The careful student of the medical institutions of the United States must most certainly admit that there is much to be desired, and much rottenness to be rooted out before they can become what they should be, and worthy of so wealthy a country and so energetic and practical a people But in speaking of the "Medical Institutions" of a country it must not be thought that the Schools alone are to be the subject of consideration *They* form one unit among many, but unfortunately for many schools, as well as for the people and the nation, it is the most important and fundamental unit in the whole organism If the foundation be weak, the whole super structure must be in a like condition

Before entering upon the discussion of this, the educational part of our question, it is necessary that we come to a clear understanding of what we mean by the "Medical Institutions' of a country To this end it is necessary that we define our ideas of medical science The ultimate endeavor, or purpose, of medical science, as we understand it to day, is not to educate *practitioners in medicine, i e*, to make "Doctors," alone, but rather to subject all disease to the most searching intellectual, physical, chemical, macro- and microscopical analysis possible, in the hope that we may thus be enabled to discover, not only the *nature of a given disease*, but also the *nature of its cause*, for all diseases have their internal, organismal or predisposing causes, as well as external or exciting causes, in order that we may elucidate means by which *to prevent the generation of such diseases* so far as possible in the future Up to the present time our endeavors in this direction have been almost entirely limited to diseases of an infectious or contagious nature

Our work in the future must also include the so-called "sporadic," or as I would term them, common, diseases of animal life, the chief cause of which is to be sought in the utter ignorance of humanity of the laws of life The "Bacillus of Ignorance" plays a much greater rôle in the causation of disease than that of phthisis, cholera, or septicæmia, will be fully as difficult of exposure, and much more difficult to combat The world needs an applied physiology suitable to the intelligence of the educated and thinking masses, as much as it does for the medical student

While Prevention is the Alpha and Omega of our endeavors, it is not always of possible attainment so that the world demands the practitioner to treat its diseases, or accidents, as well as the investigator to search into their nature and causes, and to make experiments as to their treatment The individual man naturally looks upon the practitioner as the most important of the two, because it is with him alone that he comes in immediate contact For the mass, however, and by that we mean the nation as a whole, the investigator is of far greater importance, though ignorance still so rules the world that none but the exceptionally educated have as yet recognized the value of this fact The practitioner needs to learn that even he would be at an intellectual standstill were it *not* for the men in the laboratories whom he so often styles "the theoretical and impractical men of his profession"

The medical institutions of a country are
1st The Schools
2d The Boards of Health, or its Preventive Force
3d The Practitioners

The Science of Medicine is the great *Life-saving Service of the World* The medical institutions of this country should be as much a part of its "Life Saving Service" as that brave body of men that has been organized along our sea-board and lake-coasts during the past ten years Every intelligent person must admit that if the medical institutions of this country should be a part of its "Life Saving Service," and in reality almost the whole of it, that they should also be organized and regulated in the same manner as any other branch of the public service The division of this service has already been stated, but such a classification has also another practical value

This service has been divided as follows
1st The Educational Part
2d The entire Hygienic Organization

---

[1] Read in the Section on State Medicine at the Thirty Sixth Annual Meeting of the American Medical Association

These two departments must be entirely regulated and supported by the State.

3d. The Practical Part, which must be controlled by the State, as it is subject to the Hygienic Department, but receives its remuneration directly from the individual receiving its services.

The Medical Schools are the foundation of this entire service. It has already been said that "if the foundation is weak the entire organization must be of the same character." To the Schools we have to look as the nurseries out of which we are to draw our supplies for all parts of this extended and complicated branch of the Public Service. What then is the work of the Schools?

I. The education of scientists capable of teaching others so that they may follow in their paths and become able and enthusiastic Investigators into the nature of disease, and everything having an etiological connection therewith.

II. The education of Practitioners in the principles which have resulted from such scientific researches, as well as the practical experiences of the world.

Do our schools fulfil these conditions? Emphatically, *No!* If we make a careful survey of the literature of original research, we shall be made aware of the fact that the medical schools of the United States are conspicuous by the almost total absence of recognized contributions to this important field of preventive medicine.

Practitioners are, and have been, well educated at some of these schools, but the fundamentals upon which teaching depends are nearly all borrowed from Continental authors, the practical side is largely American, and if due regard be given to what our European confreres are doing, leaves nothing to be desired in that direction.

Why is it that our schools do not fulfil all the demands that we have to make upon them?

1. Because there is not a single medical school in this country that is *properly supported and regulated by the State.*

2. Because there is not a medical school in which all the teachers have been selected for their abilities not only to *teach well, but to investigate better.*

3. Because there are no schools offering free opportunities to men of distinguished ability to work and teach as "private docents," thereby giving genius a chance for self support, and enthusiasm an opportunity to extend over the land.

4. Because we have no school where education is free, where the one purpose is to fulfil its whole duty as a *branch of the public service.*

These ends can only be attained by a National Institute of Medical Sciences, supported and regulated by the Government through a well selected National Board of Health.[1] To this should be added a department of Comparative Medicine and Vegetable Physiology and Pathology.

Endowed schools can never meet these requirements. All such schools are private, in that they form no part of the Public Service of the State. They can never, to eternity, shake off the evil influences which they have inherited from their inception. Speculative schools will not even let science enter their doors, save as they must in the form of honeyed misrepresentations to attract the students flying round after cheap and easily-obtained diplomas. Up to the present time every medical school that has been established in the United States has been for the sole purpose of making practitioners. The majority of those that I have classed as "Endowed" *are honest schools*, and were established in the earlier days of their respective States to meet a public necessity. The country was young then, almost the entire population being busied in developing it. Drones and sick people were a luxury the earlier settlers could not afford to have with them. The first they drove out, and they desired the sickness driven out of the others. The intelligence of the country has not augmented in any proportion to its increase in wealth and population. It still fails to grasp the mission of medical science in the world, and to realize that its executive institutions should be a part of the Public Service of the State. It does not realize that research is the foundation of all knowledge, or that "*Knowledge is*—the—*Power*" by which alone we are enabled to prevent the ravages of disease. It still demands *curers* only.

If we are called before a committee of one of our legislative bodies with regard to any disease that is making itself unpleasantly frequent, they ask us, "What can you do to cure it?" not what is its nature, and if we speak of research into its nature, and the necessity of money and time to make investigations with the hope of preventing it, they immediately put us down as a "crank."

The other class of schools, the speculative (to which should be added a new variety, lately imported, of veterinary schools, that run their hospitals upon a "subscription" basis), although incorporated, are only to be condemned. They are the result of unscrupulous greed on the part of selfish and ambitious men, who desire to increase their influence and incomes—at any cost to the profession—by being thus enabled to pose as "the learned Professor" before an unreflecting public, as well as from the fees of students for whom they feel no responsibility either with regard to the quantity or quality of education given them, and on the other hand, of the action of ignorant, irresponsible and unthinking legislators that are willing to charter anything. In their endeavors to get students—and the faculties of these speculative schools have very capacious maws—they send the most astonishing catalogues broadcast over the land, in which they state their advantages one over the other. These illustrated pamphlets remind one very strongly of the advertisements of summer hotels and boarding houses. The buildings and surroundings are very imposing—upon paper—and there is very great similarity in the characters of the proprietors.

In the one case they care nothing about the intellectual food which their patrons receive, as in the other with regard to the bodily, they are both alike in demanding prompt and full payment.

In 1876 we had some sixty, while in 1885 we are credited with having 134[1] medical schools in the United States. In some States there are as many as eight of these institutions and in at least one of our cities there is the same number. The majority of these schools are of the speculative variety. As they are in no sense of the word of public service, there is no valid reason for their existence. No branch of the public service should have even the suspicion of speculation hovering over it, though all parts of this service should be conducted after the the most rigid and exact business principles. What do we mean by "business principles" with reference to medical schools? The returns which the people have a right to expect are the same as in any other branch of the Public Service. *Absolute devotion to the duties of the State.*

---

[1] The time has come when we should agree to make Washington the Central Light of America in Medicine.

In this Public Health Service, especially its educational part, only the enthusiast is fitted for the work. This spirit can never result from our present medical school system.

It is said that "there are no classes in America." This is not true; we have every class of worthy and unworthy society save the most important one of all to the continued development of the country, the preservation of the Public Health and increase of the Public Wealth—the Scientific class. We must have a class of original investigators in the service of the Government as teachers also, who, like the army, are paid by the Government, and subject to pension on retirement. Un American or not, in the face of the ignorance of the land, I say, we must adopt this system before we can be called an enlightened nation. This class forms the sappers and miners who prepare the way and make possible the success of every other class in the world. Without this class of what worth is the accumulated wealth of the world when disease threatens? In the face of cholera the millionaire for once bows in proper humility to knowledge; the practitioner for the nonce loses some of his self conceit, and the world looks at the work of the investigator. The people cease to cry for "cure-alls," but rather demand that the pest be prevented from landing on our shores. Science is the continued search after new facts, and the truth. Without science the world would finally come to a standstill, and riches be valueless; they would simply consume themselves. Science is the equalizer which makes possible new endeavor, and by her discoveries revolutionizing business frequently breaks the back of monopolies, giving new courses to wealth.

Let us look at some of the evil results of our medical school system.

I. Not being scientific, *i. e.*, investigating, schools, they have exerted but little influence towards the advancement of medicine in the country.

a. The reason for this is

1st. Not being State schools, they have constantly to struggle for existence, which gives

2d, Lack of funds.

This condition has been rendered still worse by the idiotic chartering of speculative, opposition, or special schools of medicine in numerous States and cities, so that the income from students' fees has been rendered unnecessarily small.

b. The endowed schools have, for this reason, been obliged to depend upon men as teachers in the fundamental branches of medical education who had had no especial fitness for the work, *except that they were born rich, and that some relative had been one of the original founders of the school.*

c. These two conditions—poverty and nepotism—have exerted a most unfortunate influence in limiting the freedom of the trustees in their selection of teachers and preventing them from seeking genius wherever they could find it.

They are not permitted to buy their goods in an open market, but like the American ship owner, must take what he can get, "cheap and nasty" or not, as the Germans said of their Centennial exhibit in this country.

II. The great number of these medical schools, and the fact that the majority of them are speculative, tends to lowering the standard of education, and to the production of an utter want of uniformity in the quantity and quality of education acquired by graduates from different schools either in the same or different States, or what is more disgraceful, in the same city.

III. This evil condition of things has resulted in bringing unnecessary disgrace upon an honorable profession, and of lowering the appreciation of the same in the public mind. More incompetent than really trustworthy practitioners have thus been enabled to represent themselves as "M. D.'s" or "Doctors."

IV. So little appreciation have the people of the majority of the States of the value of thorough education in medicine, that it has thus far been impossible to find intelligence enough in their representatives to *regulate the practice of medicine* in order to protect the public and reward honest endeavor by passing a law to prevent charlatans from using the title "Doctor" as a manner of deception.

Medicine being a part of the Public Service, it should be regulated by the State. If one introduces the questions herein brought to discussion to the attention of the most intelligent of our teachers, or practitioners, he is invariably met with this answer: "*Yes, these things are all too true, but how are they to be obviated? You must remember that we are but a young country yet.*" I may be mistaken, or perhaps over conceited, but I think I have given more thoroughly honest and sceptical study than any one in this country for the reasons: 1. That I desired to have all these evils avoided with regard to veterinary schools; 2. That it is my present ambition to do my part towards out-rooting these evils from all medical teaching in the United States.

The causes of these unfortunate conditions are not to be sought in the youthfulness of the United States in comparison with other nations, for it must be remembered that the settlers and immigrants to this country brought and bring with them the average intelligence of their native lands, but to two other circumstances, and nothing else. 1st. Our English inheritances. 2d. That we have a representative form of government—i.e., are a Republic—which does not represent the acme of intelligence in the country by any means.

---

[1] Boston Herald.

Our English Inheritances.—There has been, or is, no better appreciation of the true relation of medical science to the public in Great Britain than America. There is no such thing as organized State Medicine in Great Britain or in any of her dependencies. There, as here, all the medical schools are either endowed, or chartered speculative institutions. There, as here, you can find the only veterinary schools in the world that are conducted on the "subscription plan," regardless of every principle of professional honor. They are all "Doctor" makers, nothing more. The government assumes no responsibility as to how the instruction is being given or the examinations conducted in the British medical schools. There is scarcely any organized research at the schools, the British government is opposed to it. It believes in upholding ignorance and putting restrictions upon knowledge. It does not support "Preventive Medicine." It places itself on the side of ignorance, prejudice and sentimental gush—a Holy British Trinity—by enacting a law against the intelligent use of vivisection. It drives such men as Lister to the Continent to gain knowledge by which human life is to be spared and disease prevented by this senseless law. The British government is an improvement on ours in some respects, in that if it does not regulate the medical schools, it has allowed the respective professions to select their own examining and diploma granting bodies, and by prohibiting to charlatanry the use of titles belonging to the regular graduate has shown that it has some regard for honesty and its duty to the public. Great Britain has neither a well organized Public Health or Veterinary Police Service. All this ignorance our ancestors brought with them, and we have not improved an iota since that day, in fact, we are far behind Britain yet, for she does not protect, cherish and nourish the pestiferous diploma mills which disgrace many of the States of this Union.

The absurd degree to which we have nationalized the idea of the "rights of the British freeman," or individual citizen, and failed to appreciate the fact that all such rights at once cease when they cause injury to another, or to the masses, finds its expression in our doctrine of "State rights," and in the senseless opposition to all laws having relation to questions of public health, animal diseases, or for regulating the practice of medicine. We do not yet know, either as a people or as governments, the meaning of either of these terms. In the United States, the people of which boast so much about their prosperity and intelligence, there is scarcely any such thing as State Medicine. No efficient Boards of Health, no trustworthy milk inspection, no inspection of dairies in order to guarantee to the public that the milk they consume or feed their babes upon is not drawn directly from ill fed and housed cattle, or from cows diseased with garget, or what is far worse, tuberculosis, no thorough meat or market inspection. Not a State in this Union gathers reliable statistics upon these vital questions. Our Boards of Health are a farce, composed of men the majority of whom have more knowledge of "ward politics" than of their technical duties. Not one of the States has a suitable laboratory at its disposal wherein investigations and experiments can be constantly made.

The question of questions is: Why are these conditions peculiarly characteristic of English speaking countries? It is an axiomatic fact that the more "English" a people are the more inefficient their government upon all questions of the kind we are considering. Another fact of like nature has long since made itself evident to every careful student of the industrial sciences. That original research has prospered and at present flourishes among the great civilized nations of the world in a direct ratio to the non republican character of their governments. In other words, the history of Republicanism gives direct evidence that thus far it has been utterly unequal to the appreciation of the great cardinal principle of national prosperity, that "*Public Health is Public Wealth*," that this condition cannot be attained, or maintained, without the careful regulation of the medical institutions of a country as a part of the Public Service, that the entire system is embraced under the term of State Medicine. From these standpoints every Republic and every extremely liberal government has been a failure.

Again, wherever we see science flourishing, and original research flourishing under a republican banner, as at present in France, it is not due to republican statesmanship, but rather that the Republic has inherited, and had sense enough to retain, or indolence enough to let alone, the good of the monarchical institutions which in other ways it superseded. Monarchical France made possible the work of Bichat, Cruveilhier, Laennec, Dupuytren, Magendie, Claud Bernard, Pasteur, Chauveau, Toussaint and others, and monarchical Germany has given opportunity to Mueller, Helmholz, Du Bois-Reymond, Ludwig, Webber, Rokitansky (of Vienna), Gegenbauer, Virchow, Koch, Gerlach, Bollinger, and so many others that the world can never pay the debt that it owes such governments for appreciating the fact that the world owes such men a living, and giving it to them, so that they have been enabled to devote their lives to its service.

Put Britain and America upon the stand, and question the Hand that records the immortal deeds of the men of medical science. *How much have you done to support original research?* We turn over the book in vain, the leaves devoted to the American and British governments are—blank. Perhaps it is thought that I am in favor of a monarchical form of government? Of that there is no danger, but here we are faced by conditions necessary for the well being of every nation, and by the singular phenomenon that thus far in the history of the world wise legislation has not been adopted by or flourished under the banners of liberal governments. Everything that is of public importance is of a political nature, and not one deserves a higher, more disinterested, or non partisan statesmanship than the question of Public Health. All questions with reference to the medical institutions of a country bear so intimately upon its prosperity that all wise thinking men who neglect them, or who would leave them to the consideration of the ordinary lay-politician, are false to their duties

The question then left for us to consider is Why is it that original research in medicine has prospered under energetic monarchical governments, and public health organizations found their most complete development, and not under liberal governments?

The answer is In governments "of the people, by the people, for the people," the masses never think of anything outside of their daily routine life they follow in the ruts already made for them, and leave the interests of the country entirely in the hands of party leaders who make a business of politics and not a science of statesmanship Only when the political affairs of a country become pathological,—that is, the life of the body politic is threatened, does the the average citizen,—the intelligent masses—awaken from his political self complacency and place his intellectual horoscope beyond the party ruts and take any active interest in the welfare of the public of which he is a member Pathological politics leads to the development of the mugwump, and to true statesmanship If the pathological conditions threaten the vitality of the ordinary citizen's pockets he awakes to the danger much quicker than when only his health is endangered, and even less quickly when the danger is of a general and not local nature So long as the cholera is in Europe and business prospers in this country, the American citizen scarcely thinks it of any account

The American Government takes no part in the etiological researches of the world It offers $25,000 as a prize to the discoverer of the cause of yellow fever, but not a cent to pay him for, or during, his labors, and if he dies of the disease during his studies, it cares nothing what becomes of his family

With cholera at our doors, the citizen suddenly wakes up and begins to wonder how it came there He now wants legislation, which, like his restaurant dinner, must be half done and served in a hurry It is the result of practical experience that has led monarchial governments to the appreciation of the fact that "public health is public wealth," and that there must be such a thing as State Medicine

Whatever tends to render the State prosperous is directly beneficial to, or shared in, by the government, and whatever tends to *injure* any national interest, and the public health is the greatest, at *once* reacts unpleasantly upon the government Let us make this apparent by some examples The balance of power, other things being equal, was at *once* placed on the side of Germany by the presence of cholera in France during the past summer The loss of 100,000 men by either of these nations from disease would be liable to have an instantaneous effect upon the peace of Europe and the stability of some of its governments Again, there is a bovine pest, unknown to this country, but known to Europe as the "rinderpest," which is to cattle what the cholera is to men Were this cattle plague to break out in either of the countries named, it could cause such losses in both food material and resources as to decidedly weaken the afflicted nation Hence it is that an active veterinary police and public health organization is not only in the interests of every individual citizen, but also to the self interest of every government No government is true to its duties that does not support State Medicine and regulate it

In speaking of these conditions previously I have called attention to the favorable geographical and political situation of the United States We are "monarch of all we survey" We have no jealous and powerful neighbors to force our government to make a careful study of every little thing which may advance or interfere with the strength and prosperity of the country Public health is not, as in Germany, a national necessity We are not, as Heine said of his married countrymen, "*raising food for French cannon*" It is not necessary that we watch over the healthful condition of this food, or to see that it itself has food enough that the cannon may not suffer for material, or that we have not more food for them than an opposing nation can consume, and thus overrun our boundaries and wage war among our cities, or devastate our harvest fields Not one of these questions strikes directly at the vitality and prosperity of our Government, and the same is true of that of Britain itself But if public health is not with us as a national necessity for these reasons, it is still of vast importance as a matter of public wealth, *i e*, to our national prosperity

No one organ of a body can become badly diseased without the others suffering, so, no one locality of a nation can become the seat of some death dealing epidemic without influencing the remainder according to the violence of the outbreak and the importance of the interests thus interfered with The rinderpest starting on the Atlantic coast and extending westward over the country would cause an immense amount of loss and misery to many individuals, the cholera may cost us many lives, and interfere with business, but not one, or all of these things will, or can, cause the least trouble to the Government on account of our situation The unharmed citizen does not fear that because his country is thus momentarily weakened, his sleep will be broken by the clarion sounding 'To arms!" Stocks rise and fall, and he profits thereby

It is the duty of every government to study the needs of the people, to support research in order that all the resources of the country may be developed, and new ones found, that the people may, in confidence, pursue their daily vocations, and not wait, as is the case with us, until public excitement makes the government act There is always danger in delay The "wolf" finally comes to governments, and nations as well as the sheep suffer All true governments must be parental, whatever their constitutional form may be

I have already shown what form it should take so far as the medical profession have a duty in the matter Coming back, then, to the question of State Medicine, we find that we have in reality to deal with very serious pathological conditions The first difficulty is to know what to do with our school system and its numerous inequalities? We are well aware that there are altogether too many medical schools in the country. In the future we must endeavor to increase the quality, and not the quantity of graduates. We cannot fall back upon Examining Boards elected by the profession, and authorized by the Government to issue diplomas, as is the good fortune of our confrères in Britain. The schools are too many, the profession too split up to make this practicable. A reform can only be made possible by the concerted action of every true man in the medical profession in the United States.

Every medical school in the country must be made, by laws common to each State, to begin and end its course on the same day of the same month each year, and to have exactly the same number of courses.

The education must be made approximately the same in all of them from the qualitative point of view.

We must unite and have a legal stop put to the endowing, or incorporating of any more schools in States where one endowed school already exists.

There is no necessity for any special schools. The charters of any schools that cease teaching in any State where one endowed school still exists—it matters not to me if the surviving school be Homœopathic—must be cancelled forever, and no new one chartered, the remaining school must be made scientific by State force.

We must all do our best to strengthen the best endowed school in our respective States—irrespective of our Alma Maters—no matter how conservative, or mismanaged it may be. It is a better policy to reform such than to weaken it by starting a weaker opposition school. We must remember that medicine is a profession and not a business, and the schools must be made to pay by delivering good goods.

The question of what shall be the examining and diploma granting power is surrounded with difficulties, many of which would be removed were all the above conditions complied with. Given, State schools, then none but the Faculty should be the examiners. Under existing circumstances, it would seem as if this power should rest in the State Board of Health, which should not be, as in Massachusetts, one of lunatics and paupers as well. A Board of Health should be composed of a number of the most advanced specialists upon Hygiene in the State, and a Hygienic Engineer and competent jurist. It matters not what party they belong to or what church they attend.

The Regulation of the Practice of Medicine.—It is now too late to make all the schools State institutions, still, they should all be made to wheel into line and be made a part of the Public Service of the State. This is not the difficult task it appears to be. The Board of Health must be the examining, diploma-granting, and licensing-to practice body for each State, and the schools must govern themselves accordingly.

Schools not coming to terms, or persisting in sending out too many incompetent graduates, to be permanently closed by law after due notice. The thing is to kill out this school pest, which is as infectious as the cholera. It must be made impossible for any person to practice medicine in any State as an "M. D.," "Doctor," "Doctress," "Physician," or "Surgeon," without having first passed the legal examination, and received the diploma and license of the Board of Health of said State. A record must be kept of all students graduating, description of person, age, parentage, etc., and number of license. When said graduate settles for practice in a given locality in said State, said license must be shown to the local health officer, or selectmen, who should take its number and verify it by correspondence with the State Board of Health.

Practitioners who have practiced medicine under the above conditions in another State should, on leaving said State to remove to another, have their license endorsed by the Secretary of the Board of Health and local officer of the State where he has been in practice. If the conditions in said State are accepted as equal to those of the State into which he moves, the Secretary of the Board of Health will simply verify his license, and he shall be allowed to practice under the above conditions.

The public health organization is thus made to hold in its hands the keys by which to lock up quackery and incompetency within the narrowest possible limits. We have already removed the charm of the charlatan by taking away from him all the titles by which he can misrepresent himself to the public. The power to check swindling of the same nature should also be given to the State Board of Health with reference to the use of the same titles by the "patent medicine" proprietors in their advertisements. Honesty is all we demand. We want no protection—but the public does.

The medical service of the country should form one comprehensive Public Health Organization. It should include the veterinary police, all kinds of animal, vegetable and food supplies, and the regular, veterinary and irregular practitioners in its group. It should begin with a National Board of Health at Washington, and State Boards in each State.

We will limit ourselves to the consideration of a State organization. Aside from the State Board, there should be local boards in each city and large town. The country districts are now conveniently divided into counties, each of which should have its chief health officer and veterinary police official, the counties should be districted, and each district should also have its official representing preventive medicine in each profession. The markets and slaughter houses in the State should all be State or local property, no large food animals should be killed outside of them. The State should appoint the inspectors. None of these officials should be appointed by the local authorities. All should be paid by the State. All should hold position during active life, or up to an age fixed by law, no removals should occur except for cause, not political. The medical official should replace the coroner in his district. If injured during public service so as to unfit him for future usefulness, or dying from injuries received therein, the public health official, or those directly dependent upon him, should be subject to pension.

The medical officials of the State Board of Health must of necessity be at first appointed by the Governor, the engineer and jurist should be selected by the medical officials. All local officers should receive their appointment only after having shown their fitness by examination before the State Board. All vacancies should be filled, as far as possible, by the advancement of local officers from the lower grades, the latter to be filled by competition when necessary. Vacancies in the State Board to be filled by promotion from the most able of the county officials.

The pay of this health organization should be graded accordingly. Before being eligible for competition for the positions in this organization each competitor should be obliged to attend a special course of studies, for which the State should supply all the means and opportunities free. The State Board of Health of each State should have at its disposal a well ordered laboratory with funds sufficient to make continued chemical, biological and pathological researches and experiments. A place also where any one desiring so to do could go and devote himself to the same kind of work, the State supplying the material, but not paying any such person a salary unless it made use of him. This laboratory should also serve as the place for the instruction of those desiring to compete for appointments on the health organization, and also as an advanced school of medicine for those desiring special courses in the above branches. The private workers could thereby pay their way and become useful servants to the State as well, at no cost.

Having almost completed our task, it is simply left us to show the only practical way of regulating the practice of medicine without interfering with the personal rights of the American citizen. The whole practicing fraternity, regular and irregular, human and veterinary, should be obliged by law, to report to the nearest State medical official the existence of the suspicion of any infectious or contagious disease in any person, or animal, to whom or which their services should be called. The State Board of Health should publish a list of such diseases, as well as a code of instructions and laws for the guidance of the officials and public where they occurred. Any violation of these regulations should be punished by fine, or imprisonment, according to the nature of the case. Ignorance should never be accepted as a mitigating circumstance.

THE PROMISE AND POTENCY OF CLEANLINESS.[1]

BY GEORGE HOMAN, M.D.,

OF ST. LOUIS.

The soundness and value of any opinion held concerning the origin or impulse of infectious or contagious movements taking place in the human system, or amidst human populations, must of necessity depend upon the reasonableness of the evidence brought forward in support of such view or opinion; and, of the various hypotheses advanced by different writers to explain their occurrence or beginning, as the vital cell (Beale), the nervous theory (Richardson), or the parasitic-life doctrine, as expounded by Pasteur, Koch and others, the evidence afforded by observation and experiment in favor of the last named, seems to largely out-weigh the arguments put forth in behalf of the two first mentioned.

Aside from the many nearly conclusive showings yielded by experience and demonstration—all pointing to the active presence of living particles as the influential causes and movers of displays of infectious or epidemic power—there are additional strong arguments in its favor drawn from analogy, so that the reasonableness of the statement that certain life-forms, in varied and multiplied shapes and phases, do exist, and descend in size, and recede in vital aptitude, until they pass beyond the reach of even the assisted human vision, does not admit of doubt or valid questioning.

The inquiries and findings of searchers in this domain of nature, both those who work in the panoramic field disclosed by the microscope, and those others who test and turn to useful every day account, in medical and surgical practice, the available profitable knowledge thus gleaned and gained, all tend with increasing force toward this conclusion, and toward the identification and arraignment of suspected, or accused, disease bearing or disease causing entities. Observers in this field of miniature activity and life, gave the needed substantial backing and scientific confirmation to the already existing conviction in the professional, if not public, mind that therein was to be found the lucid explanation and rationale of many morbid processes observed, which were always consistent and symmetrical in the main as regards their individual evolution and sequence, but which differed widely when compared one with another in respect of intensity of action and effect upon the economy and health of humankind, whether considered in the individual person or in the aggregate mass.

Prior to the light yielded by such investigations, that which is commonly known as dirt was generally thought to be inert, if not positively wholesome, in its nature; and the suggestion that systemic hurt, and lasting harm to health could be caused thereby was likely to be received and treated with scornful surprise and disbelief. The inflammation that often followed slight traumatic hurts, as scratches by the claws of animals, or the human finger nails, was ascribed to the poisonous nature of these structures themselves, or to a constitutional fault or vice in the recipient, and not to the foreign matter, carried or admitted by these weapons into the inflicted wounds.

The practical and dominating recognition by Lister and others of the fact that multiplying organisms, capable in themselves of much harm to health, and danger to life, may and do dwell or lie hidden in matter impalpable, and that which is seemingly most inert and innocent, compelled and centered general attention inflexibly towards this point; and from this epoch dates the gospel of exacting cleanliness which is now preached and practiced with results that mean more positive good to susceptible, diseased or wounded in primitive matter resided the promise and the po humanity than any before recorded in the annals of medicine The forms, features, functions, aptitudes and belongings of these denizens of the lesser world are being searched out, studied and described by enthusiastic explorers with as much zeal and care as the fauna and flora of the larger world have been scrutinized and arranged in classes, families, etc , their true offices in nature, and precise relationship to man, either as helpful servants, harmless visitors or guests, or as invaders warring fiercely against the powers of his life, are likewise being closely studied and defined, with results that betoken increasing good, and only good, to the human race, and, also, to the animals that have been domesticated to serve the comforts and needs of man

[1] Read in the Section on State Medicine and Public Hygiene at the Thirty Sixth Annual Meeting of the American Medical Association.

Cleanliness of the body and physical sphere of the individual, in sickness or health, is godliness already attained in the flesh, the soap and water crusade long time proclaimed for the outward cleansing has no novelty, but the suggestion of a general systemic befouling of a country or community, and in the sick, wounded or lying in, through the medium of organisms filth born and bred and dirt borne, is much newer to the public mind, and the term dirt must needs be understood as being generic in nature, and comprising matter volatile as well as solid, aqueous as well as earthy

The effective warfare waged against dirt and its abounding mischievous offspring, in the fields of medicine, surgery and midwifery, began less than a generation ago, although the vital spirit of preceding generations had been influenced somewhat by the definite, but not widely concerted, efforts of those whose minds discerned the coming light, and whose faith and works were inspired and guided by clear perceptions of the dawning and desired era of skilled and accomplished hygiene If the statement be true that "crime is begotten by sin, and sin is begotten by disease, and disease is begotten by filth, and filth is begotten by ignorance," then truly the fulness of time has come for the revelation of the truth of the generally close and evil union of disease and dirt, in the average human body, to receive full recognition and general acceptance

The term cleanliness thenceforth took on a new and deeper meaning, for with no less regard paid to the palpable and external, it descended and penetrated to the minutiae in everything designed to cripple, baffle or destroy the clearly recognised existences whose survival was not compatible with safe or wholesome human living It searched the recesses of earth, air and water, to find and purge away every possible source of harm to man, singly or collectively, by physical forces, by mechanical means, by chemical agents, by forethought and afterthought, this warfare is being carried on, and cleanliness in a public health or surgical sense, no longer means a mere soaping and wiping of hands, or a whited and pleasing exterior, but a thoroughgoing radical safeguarding, from top to bottom, and from centre to circumference, of everything and everybody susceptible or liable to the invasion or influence of the emissaries of infection that proceed from either palpable dirt or invisible foulness

The memorable declaration made [illegible]ndall [illegible] tency of every form of life, may with confidence be paralleled by the assertion that sooner or later around, about, or within us, above us, or below us, there lurk or lie dormant, awaiting the time and soil and circumstance of their fit development, the seeds or agencies that have in themselves the promise and the potency of all the spreading or wasting ills, that tell most grievously against human health and life

The purport and the practice of cleanliness carries the sanitarian, the physician, the surgeon and the obstetrician alike into a realm towards whose inhabitants it is his conscientious duty to bear no message of peace or good-will The good of the individual and the public alike requires that no truce be declared in the conflict waged against the septic or noxious generations, issuing from material uncleanness of whatever sort, circumstance or degree To unsparingly lay waste the soil or breeding places that give birth or cradle to the active causes of the fevers and fluxes of persons and populations, and to urge others to do the same, is the bounden duty of every one whose knowledge or instincts that way lie To do less is to go back to darkened times in civilization and medicine, when human habits and customs favored the uprising of disease in many forms, while the light of to day compels every reasoning person to bestir himself and starve and slay whatsoever it may be, in lowly predatory form, that finds refuge, or power, or habitation in dirt, and issues thence to threaten may be his life, or to assail the integrity of his health or physical well being

How this may best be done, may not even yet be settled to the satisfaction of all, but fortunately, along with the recognition of the untoward influence of minute organisms upon individual or general health came a widening knowledge of means and measures useful and efficient to ward off or neutralize their hurtful power The employment of sewerage and other sanitary measures and methods in behalf of population health, was followed by the development and employment in all branches of medi

OBSERVATIONS ON THE CAUSE AND TREATMENT OF INFANTILE ECZEMA AND ALLIED ERUPTIONS[1]

BY HENRY T BYFORD, M D,
OF CHICAGO

In the winter of 1880, I was called to attend Mrs R, in confinement with her fifth child Two of her other four had been born dead, the other two, born apparently healthy, had died in convulsions at the ages of three and ten months Both of the last had, before death, suffered from a scabby eruption, and become somewhat emaciated, but had not, as far as I could determine, been considered syphilitic The child born at this time was, at first, apparently healthy, but in a short time, broke out with an eruption that had the appearance of an ordinary eczema pustulosum, and which affected its scalp and different parts of its body The only other noticeable symptom was progressive emaciation

A physician seeing the child for the first time at the age of three weeks, would have been excusable, without the family history, in considering this a strumous case, and in treating it with cod liver oil Minute doses of calomel and mercurial inunctions quickly transformed the unsightly, emaciated sufferer into a healthy, well nourished infant

In the summer of 1876, I was called upon to treat a young child, Augustus G, with pustular eczema confined to the scalp, excessive nocturnal restlessness and progressive emaciation This being the first child, there being neither copper colored areolæ nor other characteristics of a syphilide, but for the acknowledgment of the father of a former but seemingly perfectly cured attack of syphilis (an acknowledgment not always made), mercurials would, as a rule, have been avoided by an attending physician Yet the eczema rapidly disappeared, and the infant was soon gaining in flesh upon calomel powders and mercurial inunctions

To contrast with these syphilitic cases, I wish to relate another in which I know there was no possibility of a syphilitic taint, as I had been in daily communication with the father for three years before his marriage, and have often treated his family since The patient, E H, one year old, was unusually fat and well nourished, and had an eczema on the head which spread over the body in patches, in spite of the prolonged local treatment of one of our most intelligent practitioners I recommended one fifth of a grain of calomel to be given twice a day, and an ointment composed of one dram of carbolic acid in an ounce of the oxide of zinc ointment After ten powders had been taken the eruption began to give up some of its area, and had almost disappeared by the time the thirty powders, first prescribed, were gone Soon afterwards the eruption began to spread again, but was promptly cured by more of the powders The child, having been overfed, was of course put upon a proper diet, by diluting the milk and infant food it was already taking, and withdrawing all other The child has since remained well

I have notes of a case of eczema, attended in 1880, in which the eruption extended to the eyelids, causing such conjunctival sensitiveness that the child lay motionless in its cradle, with its eyes bandaged by day and night Every attempt to move it or remove its bandages elicited either moans or screams I thought the child, which was a little over a year old, the most miserable one I had ever seen I prescribed quarter grain doses of calomel twice a day, to be given until they produced a laxative effect, then once a day only Carbolized oxide of zinc ointment (ʒj to ℥j) and a borax eye water were prescribed for external use Improvement did not take place until the powders had been taken regularly for several days, when it commenced, and, in a few days, rendered the little patient comfortable, and able to endure a moderate light When, later, the calomel treatment was neglected, the case relapsed, in spite of external applications, but a return to it soon cured the eruption, and improved the condition of the patient

Many other severe cases of the disease have come under my care, and whether the eruption confined itself to the head or ran all over the body, whether the patient was syphilitic or not, strumous or plethoric, they were all similarly affected by calomel When treated without this remedy, their recovery has usually been very slow, uncertain, and often temporary

It is an old popular belief, not utterly unfounded, I think, that the rapid drying up of these head eruptions by strong applications does some harm to the system, especially the nervous system With the aid of calomel and external applications, I have rapidly dried up scores of such head eruptions without having observed any but good results, and consider the coexisting digestive disorders as the causes of any head symptoms that may arise

The frequency of occurrence of eczema in infants, the large size and great activity of the liver in early life, and the striking, I might say specific, action of calomel have led me to associate liver indigestion with infantile symptoms of eczematous nature in the relation of cause and effect Even in many syphilitic cases the sallow complexion of the skin, and nocturnal restlessness, have seemed to indicate liver disorder of syphilitic origin In these cases, the alterative powders often produce an amelioration in the skin troubles, sooner than they could through their direct action upon the blood poison, and hence the mercury should be used so as to affect the liver as well as the blood

A properly regulated diet is necessary, and in some cases is all that need be recommended But the negative action of diet alone, and the increased debility that would, in the meantime, follow with strumous children, whose disordered and debilitated digestive organs would be slow to assume healthy, vigorous function, makes it very injudicious to wait for such action Some of my earlier cases were cured without any regulation of diet

While disordered digestion is usually considered an important factor in certain instances, and a regulated diet, with occasional laxative doses of mercury, are often advised, I know of no authority who has humanity than any before recorded in the annals of medicine. The forms, features, functions, aptitudes and belongings of these denizens of the lesser world are being searched out, studied and described by enthusiastic explorers with as much zeal and care as the fauna and flora of the larger world have been scrutinized and arranged in classes, families, etc., their true offices in nature, and precise relationship to man, either as helpful servants, harmless visitors or guests, or as invaders warring fiercely against the powers of his life, are likewise being closely studied and defined, with results that betoken increasing good, and only good, to the human race, and, also, to the animals that have been domesticated to serve the comforts and needs of man.

[1] Read before the Chicago Medical Society on August 17 1885

Cleanliness of the body and physical sphere of the individual, in sickness or health, is godliness already attained in the flesh, the soap and water crusade long time proclaimed for the outward cleansing has no novelty, but the suggestion of a general systemic befouling of a country or community, and in the sick, wounded or lying in, through the medium of organisms filth born and bred and dirt borne, is much newer to the public mind, and the term dirt must needs be understood as being generic in nature, and comprising matter volatile as well as solid, aqueous as well as earthy.

The effective warfare waged against dirt and its abounding mischievous offspring, in the fields of medicine, surgery and midwifery, began less than a generation ago, although the vital span of preceding generations had been influenced somewhat by the definite, but not widely concerted, efforts of those whose minds discerned the coming light, and whose faith and works were inspired and guided by clear perceptions of the dawning and desired era of skilled and accomplished hygiene. If the statement be true that "crime is begotten by sin, and sin is begotten by disease, and disease is begotten by filth, and filth is begotten by ignorance," then truly the fulness of time has come for the revelation of the truth of the generally close and evil union of disease and dirt, in the average human body, to receive full recognition and general acceptance.

The term cleanliness thenceforth took on a new and deeper meaning, for with no less regard paid to the palpable and external, it descended and penetrated to the minutiæ in everything designed to cripple, baffle or destroy the clearly recognised existences whose survival was not compatible with safe or wholesome human living. It searched the recesses of earth, air and water, to find and purge away every possible source of harm to man, singly or collectively, by physical forces, by mechanical means, by chemical agents, by forethought and afterthought, this warfare is being carried on, and cleanliness in a public health or surgical sense, no longer means a mere soaping and wiping of hands, or a whited and pleasing exterior, but a thoroughgoing radical safeguarding, from top to bottom, and from centre to circumference, of everything and everybody susceptible or liable to the invasion or influence of the emissaries of infection that proceed from either palpable dirt or invisible foulness.

The memorable declaration made by Tyndall that tency of every form of life, may with confidence be paralleled by the assertion that sooner or later around, about, or within us, above us, or below us, there lurk or lie dormant, awaiting the time and soil and circumstance of their fit development, the seeds or agencies that have in themselves the promise and the potency of all the spreading or wasting ills, that tell most grievously against human health and life.

The purport and the practice of cleanliness carries the sanitarian, the physician, the surgeon and the obstetrician alike into a realm towards whose inhabitants it is his conscientious duty to bear no message of peace or good-will. The good of the individual and the public alike requires that no truce be declared in the conflict waged against the septic or noxious generations, issuing from material uncleanness of whatever sort, circumstance or degree. To unsparingly lay waste the soil or breeding places that give birth or cradle to the active causes of the fevers and fluxes of persons and populations, and to urge others to do the same, is the bounden duty of every one whose knowledge or instincts that way lie. To do less is to go back to darkened times in civilization and medicine, when human habits and customs favored the uprising of disease in many forms, while the light of to day compels every reasoning person to bestir himself and starve and slay whatsoever it may be, in lowly predatory form, that finds refuge, or power, or habitation in dirt, and issues thence to threaten may be his life, or to assail the integrity of his health or physical well being.

How this may best be done, may not even yet be settled to the satisfaction of all, but fortunately, along with the recognition of the untoward influence of minute organisms upon individual or general health, came a widening knowledge of means and measures useful and efficient to ward off or neutralize their hurtful power. The employment of sewerage and other sanitary measures and methods in behalf of population health, was followed by the development and employment in all branches of medicine of resources and expedients to protect the individual patient or person from the bad effects of agencies begotten or nursed by the hoarded dirt of hospitals or households. Having well founded confidence in cleanliness, in the full modern meaning of the term, the surgeon for example may to day explore serous and synovial surfaces and cavities with as little fear of evil result as the skin, or mucous surfaces, were approached by him a generation ago.

The potency of cleanliness is shown by its wasting and destructive effect upon the sources and energies of the living forms that beset the health and life of man, its practice means annihilation to the many forms of existence that spring into noxious activity because of his ignorance, apathy or improvidence. The power of cleanliness being known, its promise is that mankind may, by increasing knowledge, vigilance and care, both in person and population, attain health and length of days unknown before—an achievment that will sufficiently vindicate the claim of this department of science, that increase in the span of generations and in physical capacity to enjoy life, are among its legitimate and appointed fruits and offspring.

OBSERVATIONS ON THE CAUSE AND TREATMENT OF INFANTILE ECZEMA AND ALLIED ERUPTIONS[1]

BY HENRY T. BYFORD, M.D.,

OF CHICAGO.

In the winter of 1880, I was called to attend Mrs. R., in confinement with her fifth child. Two of her other four had been born dead, the other two, born apparently healthy, had died in convulsions at the ages of three and ten months. Both of the last had, before death, suffered from a scabby eruption, and become somewhat emaciated, but had not, as far as I could determine, been considered syphilitic. The child born at this time was, at first, apparently healthy, but, in a short time, broke out with an eruption that had the appearance of an ordinary eczema pustulosum, and which affected its scalp and different parts of its body. The only other noticeable symptom was progressive emaciation.

A physician seeing the child for the first time at the age of three weeks, would have been excusable, without the family history, in considering this a strumous case, and in treating it with cod liver oil. Minute doses of calomel and mercurial inunctions quickly transformed the unsightly, emaciated sufferer into a healthy, well nourished infant.

In the summer of 1876, I was called upon to treat a young child, Augustus G., with pustular eczema confined to the scalp, excessive nocturnal restlessness and progressive emaciation. This being the first child, there being neither copper colored areolæ nor other characteristics of a syphilide, but for the acknowledgment of the father of a former, but seemingly perfectly cured attack of syphilis (an acknowledgment not always made), mercurials would, as a rule, have been avoided by an attending physician. Yet the eczema rapidly disappeared, and the infant was soon gaining in flesh upon calomel powders and mercurial inunctions.

To contrast with these syphilitic cases, I wish to relate another in which I know there was no possibility of a syphilitic taint, as I had been in daily communication with the father for three years before his marriage, and have often treated his family since. The patient, E. H., one year old, was unusually fat and well nourished, and had an eczema on the head which spread over the body in patches, in spite of the prolonged local treatment of one of our most intelligent practitioners. I recommended one fifth of a grain of calomel to be given twice a day, and an ointment composed of one dram of carbolic acid in an ounce of the oxide of zinc ointment. After ten powders had been taken the eruption began to give up some of its area, and had almost disappeared by the time the thirty powders, first prescribed, were gone. Soon afterwards the eruption began to spread again, but was promptly cured by more of the powders. The child, having been overfed, was of course put upon a proper diet, by diluting the milk and infant food it was already taking, and withdrawing all other. The child has since remained well.

I have notes of a case of eczema, attended in 1880, in which the eruption extended to the eyelids, causing such conjunctival sensitiveness that the child lay motionless in its cradle, with its eyes bandaged by day and night. Every attempt to move it or remove its bandages elicited either moans or screams. I thought the child, which was a little over a year old, the most miserable one I had ever seen. I prescribed quarter grain doses of calomel twice a day, to be given until they produced a laxative effect, then once a day only. Carbolized oxide of zinc ointment (ʒj to ℥j) and a borax eye water were prescribed for external use. Improvement did not take place until the powders had been taken regularly for several days, when it commenced, and, in a few days, rendered the little patient comfortable, and able to endure a moderate light. When, later, the calomel treatment was neglected, the case relapsed, in spite of external applications, but a return to it soon cured the eruption, and improved the condition of the patient.

Many other severe cases of the disease have come under my care, and whether the eruption confined itself to the head or ran all over the body, whether the patient was syphilitic or not, strumous or plethoric, they were all similarly affected by calomel. When treated without this remedy, their recovery has usually been very slow, uncertain, and often temporary.

It is an old popular belief, not utterly unfounded, I think, that the rapid drying up of these head eruptions by strong applications does some harm to the system, especially the nervous system. With the aid of calomel and external applications, I have rapidly dried up scores of such head eruptions without having observed any but good results, and consider the coexisting digestive disorders as the causes of any head symptoms that may arise.

The frequency of occurrence of eczema in infants, the large size and great activity of the liver in early life, and the striking, I might say specific, action of calomel have led me to associate liver indigestion with infantile symptoms of eczematous nature in the relation of cause and effect. Even in many syphilitic cases the sallow complexion of the skin, and nocturnal restlessness, have seemed to indicate liver disorder of syphilitic origin. In these cases, the alterative powders often produce an amelioration in the skin troubles, sooner than they could through their direct action upon the blood poison, and hence the mercury should be used so as to affect the liver as well as the blood.

A properly regulated diet is necessary, and in some cases is all that need be recommended. But the negative action of diet alone, and the increased debility that would, in the meantime, follow with strumous children, whose disordered and debilitated digestive organs would be slow to assume healthy, vigorous function, makes it very injudicious to wait for such action. Some of my earlier cases were cured without any regulation of diet.

While disordered digestion is usually considered an important factor in certain instances, and a regulated diet, with occasional laxative doses of mercury, are often advised, I know of no authority who has considered derangement of the liver, and its accompanying digestive disorders, as the chief predisposing cause, nor of one who has recommended calomel (or its equivalent of blue mass or mercury with chalk) as the chief remedy for the vast majority of cases In fact, most authors remind the reader that no one remedy can be generally relied upon

---

[1] Read before the Chicago Medical Society on August 17, 1885.

From the fact that many of my earlier cases got well without a regulated diet, that so much calomel produced such prompt relief, and that improved digestive power usually follows, rather than attends, the action of the remedy, I am led to believe that the cure is brought about, not merely by improvement in digestion, but by a removal of waste, irritating materials from the system, which are often the main exciting cause of the eruption And from the great efficiency of mercurial over other laxatives, I believe that the irritating materials are not only in the retained fæcal matter but also in the blood—the products of imperfect digestive assimilation and excretion There is no doubt that mercurials do much to clear up the urine and to restore normal ingredients to the fæces

Occasional doses of phosphate of sodium, and other saline aperients, act in a similar way, but much less promptly And the same may be said of castor-oil, which has proved efficacious in the hands of L Duncan Bulkley (JOUR AM MED ASSOC, July 25)

The strumous and nervous conditions so often observed may, I think, be the causes or effects of the disordered digestive organs, but are seldom the direct causes of the eruptions Even the beneficial action of cod liver oil is explainable upon dietetic principles, for pure oil is a much more proper and natural aliment for young children than oatmeal, potatoes, fresh bread, stale cow's milk, and many other table articles of diet that are daily imposed upon their immature stomachs This oil helps, like castor oil, to remove fæcal accumulations With infants fat is a normal ingredient of the healthy fæces

My excuse for ever resorting to such heroic dosing with calomel, was that a large proportion of my severe cases was traceable to a syphilitic origin, and noticing that these cases bore the remedy so well, I began to try it where I only suspected syphilis, and finally in all cases I have usually given from a quarter to an eighth grain powder, according to the age, twice a day, leaving directions that they should be discontinued as soon as purgation commenced, and afterward given as often as the bowels would tolerate them without much disturbance Their effect, more than the age of the patient, determines their size and frequency of administration

As children over two and one-half years are very liable to be salivated, I usually give them a single purgative dose of calomel every six or eight days, and trust to diet and other remedies in the meantime For instance, I was called two years ago to see a boy four years old suffering with patches of eczema about the head and upper part of body, who, although under active medical treatment, had been in about the same condition for several months, except that he was getting worse While poorly nourished and pale, he was a hearty eater, and was fed upon eggs, potatoes, oatmeal and other stimulating food, with fruit sufficient to keep the bowels regular I ordered two grains of calomel to be given at bedtime, and some powders containing each one gr of ext of pancreas (F Bros & F), three grs of bicarb of sodium, and eight grs of subnitrate of bismuth one before each meal The diet was restricted to milk, beef extract, bread, toast, crackers, rice and fruits In six days, finding some improvement, I ordered the same medicines and diet In a week more I found him greatly improved in general health and partly rid of the rash Recovery was uninterrupted, rapid and permanent, the parents having in the meantime learned how to feed him

Acute cases may, of course, be greatly benefited by protecting the inflamed skin from all external irritation This may be done by keeping it constantly covered by simple cerate purified by a few grains of carbolic or salicylic acid to the ounce, or by vaseline, the object being, as already stated, to protect, not to medicate, the skin In chronic cases, I know of nothing that will allay the itching and stimulate the skin to healthy action as quickly as an ointment composed of one dram of carbolic acid to the ounce of oxide of zinc ointment, constantly applied I have used this formula in nearly all chronic cases, and have found the combination soothing instead of irritating

That I am somewhat out of fashion with my calomel I will admit In one of our latest and best exponents of the present state of dermatological science, I find the following sentence "Lastly, patients of both classes (of eczema) are to be saved from mercury, arsenic and iodide of potassium" I can only offer as my excuse, that I have found the treatment under consideration almost uniformly successful, and that I would like to do what little I can to aid others in simplifying the management of this most fickle of all diseases, in finding the centre of this Chinese puzzle of dermatology

Finally, I would like to say that I do not think it really best to treat the majority of cases in this heroic manner, being usually forced into it by the critical impatience of parents and friends, or by the impossibility of securing a prolonged and intelligent attention to the diet I would also like to remind any who may chance to thus prescribe calomel, that unless they give it with a proper understanding of the conditions and requirements of the case, they will be just as apt to fail with it as druggists and nurses are apt to fail in curing malaria with quinine, and much more liable to do injury

FEMALE EDUCATION FROM A MEDICAL STANDPOINT[1]

BY S H HAMILTON, M D,

OF MONMOUTH ILL

The human organization ought to be, and under favoring circumstances is, much like unto a well constructed and well-regulated piece of machinery, each part of it performing its function by drafts of power upon the nerve centres sufficient for its wants. The central power should be in exact proportion to the demands of all the parts, each of which should bear a just co-relation to every other, thus securing a just division of labor, and a machine-like accuracy of movement, constituting what we see *sometimes*, perfect health. *Mens sana in corpore sano.* This perfectly developed and perfectly acting human machine is but rarely met with, from a variety of causes, some of which reach far back in the embryonic stage of existence, where the hereditary weaknesses and imperfections are no doubt stamped upon the very germ of life, and follow it to the death. Added to these hereditary causes of imperfect development, which are beyond our control, are a host of others brought about by careless management of this complex machine during its period of growth, and after maturity, which are amenable to intelligent care and professional treatment.

---

[1] Read before the Military Tract (Ill) Medical Society May 12 1885

The sexual system of woman, up to about the fourteenth year of her age (more or less) is but little beyond the embryonic state, and practically exercises no influence over her general organization. The next four or five years form an epoch in her life full of danger to her future health and happiness.

This complex group of organs must obtain, if at all, its complete development within this period. If from any cause it is sought to be deferred to a more convenient season, the golden opportunity is forever lost. The woman remains for the rest of her life a maimed creature. The responsibilities and burdens of womanhood come upon her all unprepared, and she is destined to the miserable existence of an invalid. It is not held that all sexual maladies are caused by imperfect development. Lack of intelligent care during the menstrual nisus, vicious habits, bad management in child-bed, and many other causes, produce similar results. It seems clear, however, that a very large percentage of these diseases are directly traceable to an imperfectly developed sexual system, favored by an imperfect and ill-timed system of education. Imperfect, because that the knowledge necessary for the proper care of her life as a woman cannot in the nature of things be imparted. Ill-timed, because that severe mental labor at the period required cannot be indulged in without serious injury to physical health.

I do not believe that intellectual culture necessarily dwarfs the reproductive faculty in women but it seems quite clear that it does so, obtained, as it is under our present system of education. Statistics all over the land, especially in the New England States, reveal the alarming fact that the increase of population is entirely in the lower and uneducated classes of society. The vicious, the ignorant, and the poverty-stricken hordes from over the water are multiplying rapidly, whilst the better part of our people, those most valuable to the State and society, are actually decreasing year by year. Small families or no children, is the rule among educated people.

That this deplorable condition of things is chargeable largely to our present system of education for girls, seems clear to any careful observer of its workings. There is no way of accounting for the extreme laxity in morals, and apparent recklessness of bodily injury, pervading the so-called educated class of society, than on the hypothesis of extreme ignorance. The unnatural and disgusting means of one kind or another preventive of conception, the wide-spread habit of producing abortions in the early stages of fœtal life, are surely oftener chargeable to lack of information than downright wickedness.

Co-education of the sexes, which means "identical education," under our present high school and college system, is entirely unsuited to anything like proper education for girls. It does seem like the very essence of folly to set up a common system of training, for two sets of human beings, so essentially different, in both their physical and moral needs. It is admitted that as much of mental culture as is consistent with good health, is especially required for women. The welfare and improvement of the race demand it, the happiness and comfort of both sexes require it, and it is a well established fact in the physiology of generation, that children, male or female, inherit the intellectual faculties of the mother rather than the father. Mental discipline acquired in the schools is as necessary for women as for men, but it should not be forgotten that the most important to them of all studies is the study of *themselves* as *women*, so that they may cooperate with, and intelligently use, all the necessary appliances to secure a full and healthful development of the sexual system, take proper care of the same, and be able to meet and solve correctly the various moral questions growing out of her duties as wife and mother. I know that in these days of *womanish men* and *mannish women* it has become almost a crime to talk even in a whisper about the true "sphere of woman" being confined to the so-called "narrow limits of home." Nevertheless, we will take the risk of saying, what all observation proves to be true, that just so soon as she steps outside the charmed circle of her duties as wife and mother, and wilfully neglects their fulfilment, she throws away her best chance for a happy and useful life.

The best education for girls, then, is that which best prepares them for the legitimate duties of womanhood. The time selected for its accomplishment should be chosen, and the thoroughness of the course regulated, so as to be consistent with good physical health. High intellectual culture, valuable as it is, and so much to be desired, costs too much when the price paid for it is a ruined or greatly damaged physical constitution.

The sexes are essentially different intellectually as well as physically. Extreme nervous impressibility, the strong reflex movements from the sexual system upon the intellectual nerve centres, in health and disease, the notable lack of the logical faculty, as well as muscular power, show conclusively that the requirements in the education of the female are widely different from the opposite sex, and that a system such as ours, framed as it is specially for the boy, is unsuited to the girl. She is practically cut off from the most useful of all studies, to her, minute sexual anatomy and physiology, for it is plain to any one, that these subjects cannot be properly and effectively taught to mixed classes of boys and girls Our system, as it is now framed to suit the boy, tends to *unsex* the girl If changed to suit the girl, it would unsex the boy A hybrid system would be unfit for either, and dwarf the strong characteristics of both A plan of education should be devised for each, *non-identical* and unlike, as the non identity and *unlikeness* of the mental and physical lives of the parties Our objection to identical, or, as it is called "co education" for girls, is not limited to considerations of the kind or quality of instruction they receive As before said, it is a plan of instruction elaborated specially for the boy

As a rule, girls enter high school or college about the time, or shortly after the commencement of the epoch of puberty At this time, the whole physical and intellectual being is strongly impressed by the rapid development just begun The vital forces of the body are largely employed in building up this most important portion of the human anatomy The growth of bone and muscle ceases, or is greatly retarded for the time Deposit of fat is made in the subcutaneous cellular tissue, giving to her face and figure that roundness, and softness of outline, so attractive to all who look upon her She becomes easy and self possessed in her manners, and graceful in her movements Everything about her shows that important changes are rapidly going on in her mental and physical organization, the interruption of which must be attended with peril The nerve centres are no doubt, during this time of active development, using all their surplus nerve force in this work Is it safe to subject the girl at such a time to hard and continuous intellectual labor?

It is a well established fact that brain work uses up the vital forces of the body much faster than muscular exertion, and to divert this nerve power largely from interstitial growth to mental labor, can have but one result, partial or complete arrest of the building-up process in the other direction, and if continued, the foundation is laid for long years of suffering, suffering from the vain efforts of a half formed organ to perform the duties of one fully grown "Nature can be helped or hurt, but rebels against entire suppression" The time for the education of girls established by a well grounded, but erroneous public sentiment, and by all-powerful fashion, is the most improper possible, considering their physical needs Ambitious mothers are anxious to have their daughters married at twenty (and the daughters generally concur) A good education (so called), and *accomplishments*, must be obtained against that time, be the consequences what they may As a rule, the result is, greatly impaired or permanently ruined health, a life of sterility, general unhappiness, and uselessness

It is not held that *all* female graduates of our co educational institutions are ruined thereby in physical health A few escape unhurt Many are badly injured, many ruined for life Enough damage is done year by year, to excite the gravest alarm, and the subject ought to elicit the best thought, and the serious attention of the community

With co education as a fixture any reform, in the range of possibility, can only be palliative The system is wrong from foundation to turret, and no amount of patching can make it perfect nor strip it of all its evils Nevertheless something might be done, in the way of improvement As thus Let the girls learn all they can in school, whilst they are children Then so soon as the first signs of approaching puberty appear, withdraw them at once from close application to study Let them learn domestic economy, and for this purpose, the kitchen is a rich mine of useful knowledge They should learn sewing, plain and ornamental, embroidery, music, read the daily papers, and other well selected light literature, and, above all, should take plenty of fresh air, moderate outdoor exercise, and good food Then when girlhood has given place to womanhood, the functions of ovulation and menstruation fully established, the muscular and bony structures up to their maximum of growth, then let her take two or three years of earnest, solid work, in school She will be better educated thus, and better equipped at the same time for the great duties of her life, those growing out of her surroundings as wife and mother This seems to us the best that could be done with cooperation, but the system is intrinsically faulty, in that it takes no notice of, and makes no provision for the most important fact that girls are unfitted, by the claims of exacting nature for mental labor, as a rule, about one fifth of the time They cannot work effectively, nor safely, during the menstrual period, and yet "co education" requires of them, during this period of disability, the same work exacted from the boys, who are not so disabled

Radical reform of these grave faults, in our really meritorious system of education, will be found in "schools for girls," founded upon correct physiological principles, where the girl will be recognized, and the peculiar mental and physical needs of her organization provided for One such school at least, has been in operation for several years with admirable success

Let us hope then, as it is not an experiment, but a well digested, and well tried enterprise, founded upon the soundest reason, it will hereafter be an important factor in the solution of our educational problem

MEDICAL PROGRESS

ANATOMY AND PHYSIOLOGY

HEMIALBUMOSE OR PROPEPTONE —Another one of the proteid substances sometimes found in urine, and to which increased attention has been called by reason of the introduction of the so called delicate tests for albumen, is hemialbumose

This substance is an intermediate product in the conversion of albumen into peptone, in the act of gastric digestion It is therefore abundantly present along with albumen in the gastric contents, and, unlike peptone, is also found in the blood during digestion It is identical with the albuminous substance known as Bence Jones's albuminous body or Mulder's proteindeutoxyd found by Virchow in the bone marrow in osteomalacia, and by Fleischer in normal bone marrow

Hemialbumose, like albumen, is insoluble in alcohol, also insoluble in pure water, but very soluble in water containing only traces of acids, alkalies, or salts It is not precipitated by heat from its watery solutions as is albumen, but if the solution be made strongly acid and concentrated salt solution be added thereto, it is precipitated If the cloudy fluid be now heated it becomes transparent, but again turbid on cooling A further large addition of salt maintains the precipitate in spite of heating It is precipitated by pure nitric acid, but redissolved with the production of an intense yellow color on heating, and reprecipitates on cooling An excess of nitric acid redissolves the precipitate even in the cold, with the production of the same orange red color

In these respects hemialbumose differs strikingly from both peptone and albumen It is like peptone in that it exhibits the biuret reaction with an alkali and salt of copper, and like albumen in that it is precipitated by acetic acid and ferrocyanide of potassium

In order to test the presence of hemialbumose the albumen must first be removed This is accomplished by acidifying the urine with a few drops of acetic acid, adding about ⅙ its volume of concentrated salt solution, boiling and filtering off the precipitate The filtrate is then allowed to cool, and if a turbidity arises or is produced by the further addition of salt solution, which disappears by heating, and reappears with cold, propeptone is present

Hemialbumose is removed from fluids by adding acetate of iron and boiling, or by boiling with hydrated lead oxide

Hemialbumose was first found in urine by Macynter and Bence-Jones, in the disease known as osteomalacia, and by Lassar in artificial nephritis —*Medical News*, Aug 15, 1885

MATERIA MEDICA AND THERAPEUTICS

Jequirity in Lupus Exedens and other Chronic Ulcerations —Dr Arthur Hawies gives the following as his experience

The berries are macerated for 24 hours to soften the husks, which are then carefully picked out after bruising in a mortar The remainder is crushed with half its weight of glycerine and three times its weight of water, until a *smooth paste* is produced This is plastered thickly over the diseased surface and retained in position by a piece of beef After 24 hours the patient begins to complain of malaise, with slight thirst and some quickening of the pulse, these symptoms lasting 48 hours, never less There is scarcely any increase of temperature (in one case the temperature rose to 100 5° on the third day after application)

On the third day suppuration has commenced, and an unpleasant smell from the dressing is perceptible On the fourth day and subsequently, the suppuration is more profuse, the *smell* is very marked, to the extent of necessitating the placing of deodorants in the ward and in the neighborhood of the patients, the malaise disappears, and the patient's appetite improves in spite of obvious inconveniences

On the tenth day the dressing is removed, a healthy granulating surface is exposed, having the following peculiarities The circumference is diminished by about one-third, the new skin at the margin exhibiting the typical bluish tint of a healing ulcer, and from the sides of the sore a little promontory of new, healthy tissue is seen attempting to reach a fellow projection on the opposite margin The appearance of this new tissue is like that of the margins After two or three days' dressing with a simple astringent lotion (in his cases consisting of the potassio tartrate of iron dissolved in water, gr iv ad ℥j), these projections have coalesced, thus bisecting the original sore, while the edges of each part continuing to granulate healthily, the isthmus becomes broader, the sore surfaces smaller, until, at the end of about ten days after removal of the dressing, a fairly sound surface is left

He has not found the treatment applicable to dry tuberculous conditions of the skin, even after scraping, so as to present a raw surface to the action of the remedy The pus escaping from the dressing swarms with bacilli, but Dr Hawies is not prepared to state whether they are active factors in the healing process, or whether they are present merely as concomitants of the conditions of application of the dressing

In jequirity he is convinced that we have a treatment of great value in *chronic* ulcerative conditions, and he certainly thinks it worth trying in rodent ulcer, and possibly even in epithelioma Jequirity should not be used in recent ulcerations—in them action is already too marked, and his experience of one case treated by a colleague has been that it caused extension rather than diminution of the sore surface —*Provincial Medical Journal*, Aug 1, 1885

Iodoform in Gout —Professor Testa (*Gazz Med di Torino*, 1885), having previously ascertained experimentally that iodoform fulfilled the requirements of a remedy for gout, *i e*, that it accelerated oxidation processes within the system, increasing the excretion of urea, and diminishing that of uric acid and oxalic acid, tried it in seven cases of gout and continued the use of the drug for months together The dose varied from 7 to 25 cgrm daily, given in two doses The remedy exercised on the whole a very favorable effect The attacks became less frequent, and their intensity and duration were diminished He thinks its use is contra indicated, or, at least, that it should be given with extreme caution, when the gout is complicated with kidney disease, as, in case it is not duly eliminated by the kidneys, accumulation of it in the system might lead to serious results —*The Medical Press*, July 1, 1885

MEDICINE

Diabetes Mellitus Cured by Removal of the Uterine Appendages —Dr Francis Imlach reports the following interesting case

K G, a widow, aged 31, consulted me on February 12, 1885, on account of leucorrhœa and pelvic pain A diagnosis of pyosalpinx was made out, and, as she seemed ill and wasted, operative treatment was suggested On the 22d, she mentioned that for a month she had been afflicted with insatiable thirst and sleeplessness, that the bowels were habitually constipated, and the urine greatly increased in quantity On testing a sample of urine, of specific gravity 1036, no albumen was found, but, on boiling with Fehling's solution, it became evident that she was passing sugar Menstruation was regular, and, though painful, not profuse All thoughts of operation were abandoned She undertook to live upon gluten-bread and biscuits, fish, meat, and buttermilk, to give up starchy food and sugar, and as much as possible to restrict her drink Soap-and-water enemata were ordered, and bromide of ammonium prescribed for the sleeplessness Under this treatment, the urine became reduced (from an unknown quantity) to five or six pints *per diem*, but, when samples were tested with Fehling's solution and by the differential density method, there was little diminution in the sugar On March 16, three minims thrice daily of Clemens's solution of arseniate of bromine were substituted for the bromide of ammonium, and, a fortnight later, the dose was increased to ten minims, but, roughly estimated, the excretion of sugar continued unaltered On April 15, she passed 2,560 grains in 24 hours As she was becoming rapidly weaker and more emaciated, she was admitted into hospital on May 15, where the anti-diabetic diet was strictly maintained On May 16, 1,200 grains of sugar were excreted On May 19, the uterine appendages were removed The right Fallopian tube was thickened in its walls, occluded at both ends, and distended with pus The left tube was thickened, but not occluded at its fimbriated extremity, and contained only a little muco-pus Both ovaries were so firmly adherent in the pelvis, that their removal was somewhat difficult The fundus of the uterus, which was bound by dense adhesions to the sacrum, was liberated The patient recovered without a bad symptom, and with a surprisingly level temperature-chart She got out of bed on the ninth day, and left hospital on June 3 Unfortunately, I am unable to add a complete account of the urine passed subsequent to the operation, as, through an error, no quantitative measurements of the sugar were made During the first 24 hours, between six and eight ounces of urine containing sugar were drawn off every six hours The specific gravity during the first six hours was 1028, next it fell to 1014, and then rose to 1034

The sugar, tested daily with Fehling's solution, gradually diminished until May 26, when it finally disappeared On June 12, the urine was normal, and of specific gravity 1020 For a week previously she had been at home on ordinary fare, except that she took no rice-pudding, and put no sugar in her tea She then took rice-pudding daily, with unlimited sugar, until June 19, when the specific gravity of the urine was 1010, and not a trace of sugar could be detected There is no longer constipation, and her strength is already almost completely restored

Glycosuria being persistent under anti-diabetic regimen, and the health worse, operation was offered as a forlorn hope Sir J Paget makes no allusion to diabetes mellitus among "the various risks of operations," but Dr Dickinson, in his able work on the subject, says that "surgery is attended with unusual danger," and Dr Wm Roberts states that "operations for diabetic cataract generally fail from uncontrollable suppuration of the eyeball" Beyond this element of danger, there was the fear lest the operation should do no good Diabetes and pyosalpinx are not known in association The patient was married ten years previously, had a still born child a year later and became a widow two years before I saw her As the pelvic pain was of indefinite origin, the pyosalpinx was probably of ancient date, whereas the diabetic symptoms were recent Still, there remained the possibility that removal of the suppurating tubes might cure the disease There was a further argument the younger the person, the less hope of ultimate recovery from diabetes "The development and exercise of the sexual functions," says Dr Wm Roberts (Renal Diseases, 4th ed , p 256), "appear to have a marked effect in increasing the liability to diabetes in both sexes, and the diminished frequency of the disease in women after the age of 45 (as compared with men) corresponds with the earlier decline of sexual activity in the female sex" And not only is diabetes less frequent among women after 45, it is also less acute, and does not kill nearly so quickly By induction of the menopause, it was hoped that the acute diabetes might become chronic —*British Med Journal*, July 11, 1885

SALICYLIC ACID IN RHEUMATISM —DR P W LATHAM, the Downing Professor of Medicine at Cambridge, in an article entitled "Why does Salicylic Acid Cure Rheumatism," lays down seven rules for its successful administration

First, the true salicylic acid obtained from the vegetable kingdom must alone be employed If you have to give large doses, avoid giving the artificial product obtained from carbolic acid, however much it may have been dialysed and purified An impure acid will very quickly produce symptoms closely resembling delirium tremens

Secondly, give the acid without any alkaline base A very good form is to mix 100 grains with 15 of acacia powder and a little mucilage Allow the mass to stand and harden, and then divide into 30 pills

Thirdly, place the patient fully under the influence of the drug—that is, let him have sufficient to produce cerebral disturbance—*i e*, buzzing in the ears or headache, or slight deafness, with the development of these symptoms the temperature and the pain in the joints will begin to decline To an adult he generally administers three doses of 20 grains (six pills), at intervals of an hour, and if the head remains unaffected, a fourth dose at the end of another hour, and then repeat the 20 grains every four hours until the physiological effect of the remedy shows itself In the majority of cases, from 80 to 100 grains are enough In severe cases, 140 to 150 may be required Afterwards about 80 grains a day are sufficient, and as the temperature declines, smaller quantities will develop their physiological effects, 60 or even 50 grains being then sufficient to produce cerebral disturbance It would appear that as long as the rheumatic poison is circulating in the system, the physiological effect—that is, the effect it produces in the healthy organism—does not show itself; acting as an antidote, the greater the amount of poison, the larger must be the dose of the remedy; but as soon as the formation of the *materies morbi* is stopped, then the excess of the remedy acts as it would in the healthy organism, and its peculiar physiological effects are developed. It is a very striking illustration of the difference between the therapeutical effect of a remedy, and its physiological action.

Fourthly, give the patient from 40 to 80 grains daily for ten days, after all pain and pyrexia have passed away.

Fifthly, let the patient's diet consist entirely of milk and farinaceous food for at least a week after the evening temperature has been normal. On the other hand, if the patient has meat and soup, you may look forward with fair probability to a relapse.

Sixthly, take care to maintain a daily and complete action of the bowels. Calomel is the best purgative, from 2 to 5 grains at night, followed in the morning, if necessary, with a saline draught. This is the most important adjuvant to the action of salicylic acid.

Seventhly, let the patient be enveloped in a light blanket, and with no more bedclothes than are sufficient to keep him from feeling cold. The object of the treatment now is to cool the patient, not, as in former times, to sweat the poison out of him, and the cooler he is kept the sooner will the temperature be lowered.

Dr. Latham has not yet concluded his observations, but so far he considers that though lactic acid has much to do with the symptoms, it is the excessive formation of glycocine and of uric acid in the tissues that develops the symptoms of rheumatic fever, and salicylic acid cures the disease by combining with the antecedents of these bodies, and prevents their formation. When salicylic acid is administered internally it passes off by the urine as salicyluric acid—that is, it has combined in its passage through the system either with glycocine or its antecedent, for on treating salicyluric acid with fuming hydrochloric acid, it is resolved into salicylic acid and glycocine. Consequently, in the system, by seizing either upon glycocine or its antecedent, salicylic acid takes away an essential constituent of uric acid, and so prevents the formation of this body.—*Lancet*, June 20, 1885.

EXTERNAL APPLICATION OF NITRATE OF SILVER IN SPINAL IRRITATION.—Krug recommends the local application of a weak solution of nitrate of silver against spinal irritation as preferable to the solid stick or the powder. He orders a one per cent. solution in alcohol, and directs its application not only to the seat of pain, but also to the whole neighborhood twice daily. The alcoholic solution has the advantage of allowing of a deeper penetration of the silver into the tissues, and of thus producing a sort of local anæsthesia by causing coagulation of albumen and abstracting water. Krug praises the beneficent and cooling effects of this procedure, which but rarely causes inflammatory irritation. He insists, however, that the treatment should be continued for weeks and months. Cold water compresses applied at night increase the usefulness of the silver application. This local treatment, of course, is to be regarded only as supplementing suitable internal medication.—*Schmidt's Jahrb.*, ix. 203.—*Therapeutic Gazette*, June, 1885.

DIAPHORETIC TREATMENT OF NEPHRITIS.—N. HESS, having made a number of observations on the treatment of nephritic patients by wet packs, hot baths supplemented by wrapping in blankets, and hot air baths, draws the following conclusions:

(1) The least rise of temperature occurs with packs, the greatest with hot baths.

(2) While the temperature is found to sink still further twenty minutes after the pack, it remains at the same height for an hour after both the other methods of treatment.

(3) After water baths the temperature regains its original height more slowly than after air baths.

(4) During the pack the pulse becomes slower; during the water and air baths, on the contrary, it is quickened for an hour afterwards.

(5) Under the influence of the pack respiration is moderately quickened; during both water and air baths it is still more quickened, but subsequently returns to its normal rate more rapidly than after the pack.

(6) The most powerful sudorific effects are produced by hot baths, the least powerful by packing.

(7) Though the baths are more stimulating, packing soothes the action of the nervous system, brings the patients on better, and produces a subjective feeling of improvement afterwards.—*Lancet*, June 27, 1885.

SHOCK AND ITS TREATMENT.—In a critical study of shock intended to elucidate its pathological relations, GRONINGER, of Berlin, defines shock as an exhaustion of the medulla oblongata and the spinal cord produced by violent excitation. This definition is no doubt perfectly proper, though it strikes us as if the term "exhaustion" is not sufficiently clear for defining purposes.

He recognises the following varieties:

1. The lowest grade of shock, which causes no appreciable effects.

2. A middle grade, which weakens sensation.

3. A high grade, which extinguishes qualitative sensation.

4. A highest grade, which eradicates both passing and permanent sensations of every kind.

His views of the treatment are noteworthy.

Energetic counter-irritations of the skin are to be excluded as useless and even dangerous.

Abstraction of blood is contraindicated.

Transfusion of blood can only be thought of in cases of great loss of blood.

Opium and chloroform are of no value whatever in shock, while digitalis is worthy of further study.

month she had been afflicted with insatiable thirst and sleeplessness, that the bowels were habitually constipated, and the urine greatly increased in quantity. On testing a sample of urine, of specific gravity 1036, no albumen was found, but, on boiling with Fehling's solution, it became evident that she was passing sugar. Menstruation was regular, and, though painful, not profuse. All thoughts of operation were abandoned. She undertook to live upon gluten-bread and biscuits, fish, meat, and buttermilk, to give up starchy food and sugar, and as much as possible to restrict her drink. Soap-and-water enemata were ordered, and bromide of ammonium prescribed for the sleeplessness. Under this treatment, the urine became reduced (from an unknown quantity) to five or six pints *per diem*, but, when samples were tested with Fehling's solution and by the differential density method, there was little diminution in the sugar. On March 16, three minims thrice daily of Clemens's solution of arseniate of bromine were substituted for the bromide of ammonium, and, a fortnight later, the dose was increased to ten minims, but, roughly estimated, the excretion of sugar continued unaltered. On April 15, she passed 2,560 grains in 24 hours. As she was becoming rapidly weaker and more emaciated, she was admitted into hospital on May 15, where the anti-diabetic diet was strictly maintained. On May 16, 1,200 grains of sugar were excreted. On May 19, the uterine appendages were removed. The right Fallopian tube was thickened in its walls, occluded at both ends, and distended with pus. The left tube was thickened, but not occluded at its fimbriated extremity, and contained only a little muco-pus. Both ovaries were so firmly adherent in the pelvis, that their removal was somewhat difficult. The fundus of the uterus, which was bound by dense adhesions to the sacrum, was liberated. The patient recovered without a bad symptom, and with a surprisingly level temperature-chart. She got out of bed on the ninth day, and left hospital on June 3. Unfortunately, I am unable to add a complete account of the urine passed subsequent to the operation, as, through an error, no quantitative measurements of the sugar were made. During the first 24 hours, between six and eight ounces of urine containing sugar were drawn off every six hours. The specific gravity during the first six hours was 1028, next it fell to 1014, and then rose to 1034.

The sugar, tested daily with Fehling's solution, gradually diminished until May 26, when it finally disappeared. On June 12, the urine was normal, and of specific gravity 1020. For a week previously she had been at home on ordinary fare, except that she took no rice-pudding, and put no sugar in her tea. She then took rice pudding daily, with unlimited sugar, until June 19, when the specific gravity of the urine was 1010, and not a trace of sugar could be detected. There is no longer constipation, and her strength is already almost completely restored.

Glycosuria being persistent under anti-diabetic regimen, and the health worse, operation was offered as a forlorn hope. Sir J. Paget makes no allusion to diabetes mellitus among "the various risks of operations," but Dr. Dickinson, in his able work on the subject, says that "surgery is attended with unusual danger," and Dr. Wm. Roberts states that "operations for diabetic cataract generally fail from uncontrollable suppuration of the eyeball." Beyond this element of danger, there was the fear lest the operation should do no good. Diabetes and pyosalpinx are not known in association. The patient was married ten years previously, had a still-born child a year later and became a widow two years before I saw her. As the pelvic pain was of indefinite origin, the pyosalpinx was probably of ancient date, whereas the diabetic symptoms were recent. Still, there remained the possibility that removal of the suppurating tubes might cure the disease. There was a further argument: the younger the person, the less hope of ultimate recovery from diabetes. "The development and exercise of the sexual functions," says Dr. Wm. Roberts (Renal Diseases, 4th ed., p. 256), "appear to have a marked effect in increasing the liability to diabetes in both sexes, and the diminished frequency of the disease in women after the age of 45 (as compared with men) corresponds with the earlier decline of sexual activity in the female sex." And not only is diabetes less frequent among women after 45, it is also less acute, and does not kill nearly so quickly. By induction of the menopause, it was hoped that the acute diabetes might become chronic.—*British Med. Journal*, July 11, 1885.

SALICYLIC ACID IN RHEUMATISM.—DR. P. W. LATHAM, the Downing Professor of Medicine at Cambridge, in an article entitled "Why does Salicylic Acid Cure Rheumatism," lays down seven rules for its successful administration.

First, the true salicylic acid obtained from the vegetable kingdom must alone be employed. If you have to give large doses, avoid giving the artificial product obtained from carbolic acid, however much it may have been dialysed and purified. An impure acid will very quickly produce symptoms closely resembling delirium tremens.

Secondly, give the acid without any alkaline base. A very good form is to mix 100 grains with 15 of acacia powder and a little mucilage. Allow the mass to stand and harden, and then divide into 30 pills.

Thirdly, place the patient fully under the influence of the drug—that is, let him have sufficient to produce cerebral disturbance—*i. e.*, buzzing in the ears or headache, or slight deafness, with the development of these symptoms the temperature and the pain in the joints will begin to decline. To an adult he generally administers three doses of 20 grains (six pills), at intervals of an hour, and if the head remains unaffected, a fourth dose at the end of another hour, and then repeat the 20 grains every four hours until the physiological effect of the remedy shows itself. In the majority of cases, from 80 to 100 grains are enough. In severe cases, 140 to 150 may be required. Afterwards about 80 grains a day are sufficient, and as the temperature declines, smaller quantities will develop their physiological effects, 60 or even 50 grains being then sufficient to produce cerebral disturbance. It would appear that as long as the rheumatic poison is circulating in the system, the physiological effect—that is, the effect it produces in the healthy organism—does not show itself, acting as an antidote, the greater the amount of poison, the larger must be the dose of the remedy, but as soon as the formation of the *materies morbi* is stopped, then the excess of the remedy acts as it would in the healthy organism, and its peculiar physiological effects are developed. It is a very striking illustration of the difference between the therapeutical effect of a remedy, and its physiological action.

Fourthly, give the patient from 40 to 80 grains daily for ten days, after all pain and pyrexia have passed away.

Fifthly, let the patient's diet consist entirely of milk and farinaceous food for at least a week after the evening temperature has been normal. On the other hand, if the patient has meat and soup, you may look forward with fair probability to a relapse.

Sixthly, take care to maintain a daily and complete action of the bowels. Calomel is the best purgative, from 2 to 5 grains at night, followed in the morning, if necessary, with a saline draught. This is the most important adjuvant to the action of salicylic acid.

Seventhly, let the patient be enveloped in a light blanket, and with no more bedclothes than are sufficient to keep him from feeling cold. The object of the treatment now is to cool the patient, not, as in former times, to sweat the poison out of him, and the cooler he is kept the sooner will the temperature be lowered.

Dr. Latham has not yet concluded his observations, but so far he considers that though lactic acid has much to do with the symptoms, it is the excessive formation of glycocine and of uric acid in the tissues that develops the symptoms of rheumatic fever, and salicylic acid cures the disease by combining with the antecedents of these bodies, and prevents their formation. When salicylic acid is administered internally it passes off by the urine as salicyluric acid—that is, it has combined in its passage through the system either with glycocine or its antecedent, for on treating salicyluric acid with fuming hydrochloric acid, it is resolved into salicylic acid and glycocine. Consequently, in the system, by seizing either upon glycocine or its antecedent, salicylic acid takes away an essential constituent of uric acid, and so prevents the formation of this body.—*Lancet*, June 20, 1885.

External Application of Nitrate of Silver in Spinal Irritation.—Krug recommends the local application of a weak solution of nitrate of silver against spinal irritation as preferable to the solid stick or the powder. He orders a one per cent. solution in alcohol, and directs its application not only to the seat of pain, but also to the whole neighborhood twice daily. The alcoholic solution has the advantage of allowing of a deeper penetration of the silver into the tissues, and of thus producing a sort of local anæsthesia by causing coagulation of albumen and abstracting water. Krug praises the beneficent and cooling effects of this procedure, which but rarely causes inflammatory irritation. He insists, however, that the treatment should be continued for weeks and months. Cold-water compresses applied at night increase the usefulness of the silver application. This local treatment, of course, is to be regarded only as supplementing suitable internal medication.—*Schmidt's Jahrb.*, ix. 203.—*Therapeutic Gazette*, June, 1885.

Diaphoretic Treatment of Nephritis.—N. Hess, having made a number of observations on the treatment of nephritic patients by wet packs, hot baths supplemented by wrapping in blankets, and hot air baths, draws the following conclusions:

(1) The least rise of temperature occurs with packs, the greatest with hot baths.

(2) While the temperature is found to sink still further twenty minutes after the pack, it remains at the same height for an hour after both the other methods of treatment.

(3) After water baths the temperature regains its original height more slowly than after air baths.

(4) During the pack the pulse becomes slower; during the water and air baths, on the contrary, it is quickened for an hour afterwards.

(5) Under the influence of the pack respiration is moderately quickened; during both water and air baths it is still more quickened, but subsequently returns to its normal rate more rapidly than after the pack.

(6) The most powerful sudorific effects are produced by hot baths, the least powerful by packing.

(7) Though the baths are more stimulating, packing soothes the action of the nervous system, brings the patients on better, and produces a subjective feeling of improvement afterwards.—*Lancet*, June 27, 1885.

Shock and its Treatment.—In a critical study of shock intended to elucidate its pathological relations, Groninger, of Berlin, defines shock as an exhaustion of the medulla oblongata and the spinal cord produced by violent excitation. This definition is no doubt perfectly proper, though it strikes us as if the term "exhaustion" is not sufficiently clear for defining purposes.

He recognises the following varieties:

1. The lowest grade of shock, which causes no appreciable effects.

2. A middle grade, which weakens sensation.

3. A high grade, which extinguishes qualitative sensation.

4. A highest grade, which eradicates both passing and permanent sensations of every kind.

His views of the treatment are noteworthy:

Energetic counter-irritations of the skin are to be excluded as useless and even dangerous.

Abstraction of blood is contraindicated.

Transfusion of blood can only be thought of in cases of great loss of blood.

Opium and chloroform are of no value whatever in shock, while digitalis is worthy of further study.

Alcoholic stimulants and subcutaneous excitation are useful. Horizontal posture, application of warmth, perfect rest, and subcutaneous injection of strychnine are the most recommendable factors of treatment.—*Therapeutic Gazette*, June, 1885.

SURGERY

Treatment of Palmar Ganglion.—*The Lancet*, June 27, 1885, lays down the following rules for treatment of palmar ganglion, as in accord with the best and most recent views of surgical authorities on the subject. The first point of importance is to attempt the cure of the cases as early as possible. No good can come of delay, which merely leads to greater distension of the cyst, and is especially to be deprecated as endangering the adjoining tendons, which become stretched, and even in some cases severed, by the pressure to which they are subjected. Second, the free evacuation of the cyst and the removal of all the "melon seed bodies" it contains, whether these be free in its interior or adherent to its walls. For this purpose an incision about an inch and a half long, not a puncture, should be made in the most prominent part of the swelling, above the annular ligament, avoiding, of course, the radial vessels and the tendons, which can be felt through the skin. Pressure should be made in the palm to force out the fluid and as many of the loose bodies as will thus escape. Then a sharp spoon should be introduced, and the whole cavity scraped, to detach any "bodies" which may be still fixed to the synovial membrane. The "spoon" is much the best means of doing this. Some have trusted to injecting a fresh stream of fluid into the cyst, but this will not remove "bodies" which are still firmly adherent to the cyst wall.

Volkmann passes a large drainage-tube through the cyst, and draws it sharply to and fro, and trusts to that to detach any adherent "bodies," this is, however, an uncertain method, and if the cyst be old and large, with pouches extending from the main cavity, they escape the friction of the tube altogether. Having thus carefully removed all the contents of the cyst, whether solid or fluid, a solution of chloride of zinc, gr. xl—℥i, should be applied to the whole interior of the sac, the purpose of this being so to modify the nutrition of its lining as to prevent any recurrence of the dropsy. A solution of iodine has been used for the same purpose, and some surgeons may be inclined to use iodoform instead. The most important steps in the treatment are those to be taken to secure healing of the wound without suppuration, at any rate without septic suppuration. As a preparatory step the parts must be thoroughly cleansed before the incision is made, and the operation should be conducted under an antiseptic spray or irrigation, and some efficient antiseptic dressing should be finally applied. A drainage-tube should be introduced into the wound and passed down beneath the anterior annular ligament, and only removed when the discharge through it is reduced to a minimum.

Dr. Weiss shows that if pressure be carefully applied over the palmar part of the cyst, all retention of fluid can be carefully obviated. The hand should be kept fixed on some kind of splint applied to the extensor aspect, until the wound inflicted is healed. As soon as that is accomplished, the fingers should be liberated and the patient be encouraged to move them. The results of this treatment are entirely different from those formerly met with. When the antiseptic precautions are carefully carried out, there is no danger whatever of blood poisoning or of profuse local suppuration, and the final result is the restoration of a thoroughly useful hand. The tendons are not bound down by cicatricial bands, and after a time it may be impossible to find any trace of the previous mischief beyond a linear scar in the forearm. Weiss considers that the process of cure of the synovial cyst is analogous to that obtained in a hydrocele by injection, or in dropsy of a joint treated by injection of iodine. At present no case of a recurrence of the ganglion after a septic incision and drainage has been reported.

OBSTETRICS AND GYNÆCOLOGY

Puerperal Convulsions Without Albuminuria.—Dr. N. Vuccino, of Rodosto, writing in the Constantinople *Gazette Medicale d' Orient*, gives the case of a lady usually enjoying excellent health, except for occasional hysterical attacks, who in the fourth month of her first pregnancy was seized with a severe frontal hemicrania of quotidian type. At the end of the sixth month she was awakened one night with intense pain in the head, followed by a slight convulsion affecting the upper extremities. In the morning the writer found her suffering from general convulsions, consciousness being lost, and a bloody froth issuing from the mouth; the pulse was small and hard, but the urine was then, and continued to be, perfectly normal. Various methods of treatment having proved fruitless, it was decided to bring on the labor, which was done by injecting hot water (32°). After this had been continued for three hours and a half, the os uteri became fully dilated, and a dead child was shortly afterwards expelled. The convulsions ceased as if by magic, and in twelve days she was able to resume her household occupations. She afterwards enjoyed good health till the eighth month of her second pregnancy, when convulsions reappeared with greater intensity than before. Chloral and chloroform proving inefficacious, the continual hot vaginal douche was again employed. In consequence of the irregularity of the contractions of the uterus forceps were required. The convulsions ceased five hours after delivery, and in seventeen days she was again in her normal condition. She subsequently became pregnant for the third time, and during the second month suffered from some premonitory convulsive symptoms, which were increased by vaginal examination, these came to an end on the patient aborting. The author considers the case interesting, as showing how convulsions, due, as he believes, to a highly nervous condition of the uterus, may simulate those connected with renal and urinary mischief.—*The Lancet*, July 18, 1885.—*Medical News*, Aug. 15, 1885.

JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION,

No 65 RANDOLPH STREET

CHICAGO ILLINOIS

SATURDAY, SEPTEMBER 19, 1885

INTERNATIONAL MEDICAL CONGRESS OF 1887

A carefully corrected and official copy of the proceedings of the Committee of Arrangements for the preliminary organization of the International Congress, at its meetings in Chicago, June 24 and 25, and in New York, September 3 and 4, has been printed and sent by direction of the Secretary-General to all the medical journals in this country Examination will show that these Rules are, in all essential particulars, in strict accordance with those which have been adopted for the organization and government of preceding Congresses They not only open the doors to membership as widely as was done either at London or Copenhagen, but they confer upon the chief officers of the Congress and the presidents of Sections, acting as an Executive Committee, full power to make such further arrangements as may be necessary for the independent and successful management of the Congress in 1887 The Rules thus adopted are in no proper sense the result of any supposed compromise, but of mature deliberation on the part of the Committee of Arrangements, after giving careful attention to the nature and organization of preceding Congresses

For the present, we simply ask every candid member of the profession to give the regulations and preliminary organization now adopted an impartial consideration

THE ACTION OF DIURETICS

Our knowledge of the action of diuretics has within a comparatively recent period received very important contributions, chiefly through anatomical and physiological sources, so that now the physiology of the renal function may be looked upon as fairly well settled While to the researches of Bowman we are largely indebted for directing investigation into the correct channel, as to the anatomical sources of the urinary secretion, yet it was reserved for Heidenhein actually to prove what Bowman had foreshadowed, that the urine consists of a compound product whose elements are derived from two sources the aqueous for the most part from the vessels composing the glomerular tuft, while the solids are the product of the epithelial cells of the convoluted tubes This at once led to a more rational and thorough understanding, not only of the physiology of the renal function and of the morbid conditions most commonly interfering therewith, but also paved the way for a more comprehensive knowledge of the action of diuretic agents, both in health and disease

Several interesting contributions to this subject have recently appeared, among which we notice that of DR E LONG FOX, in opening the discussion in the Section of Pharmacology and Therapeutics at the late annual meeting of the British Medical Association, in Cardiff, South Wales Dr Fox dealt chiefly with the physiological aspect of the subject, more especially in relation to the influence of variations in blood pressure in increasing or decreasing the excretion of the urine, as affected through nervous influences upon the circulation, both renal and systemic After refering to the now established fact, that the function of the malpighian body is mainly that of filtration, while that of the epithelium of the convoluted tubes is mostly to secrete (or excrete) the solids of the urine, *plus* a small amount of filtration, he points out that diuresis depends on conditions that facilitate filtration, in other words, the amount of urine depends upon the difference in degree of pressure between the blood in the malpighian tufts, and the pressure within the convoluted tubes The renal tubules being normally patent, all that is necessary to increase the quantity of the urine, is to raise the blood pressure within the vessels of the tuft Increase of the force, or in the rapidity of the cardiac contractions, stimulation of the vaso constrictors of arteries other than the renal, or paresis of the latter, all bring about the above result Ammonia, alcohol, digitalis, etc , act in the first-named manner, the external application of cold in the second, and the emotion of fear is an example of the last, all producing well known diuresis The cells lining the convoluted tubes performing the office of separation of solids from the blood, it is evident that conditions of vascular pressure affect this function only slightly, to some extent it must be admitted it is true, for slight filtration must take place, as Senator says, in order to carry out the solids in solution, "for no true gland yields a secretion free from water," but in the main, the epithelial cells are influenced by special stimuli, of which urea, uric acid, etc., are probably normal ones, and certain salines, notably salts of potash, lithia, soda, etc., are artificial ones. Certain agents both dilate the renal vessels, and stimulate the renal cells, thus exerting a compound action, the most important of which is juniper. Dr. Fox draws the deduction, that to call forth renal activity most efficiently as a whole, it is best to effect a union of diuretics, combining with those which cause vascular fulness, those that stimulate the renal cells, herein securing more thorough depuration of the blood.

So much for the physiological action of diuretics, unfortunately, however, in therapeutical use, this class of agents are proverbially uncertain in their action, "often proving most disappointing where most needed," partly, as might be expected from what has just been said of a few of the many influences that effect, local or general vascular pressure, but more especially as the result of the various pathological changes arising in renal disease, which interfere anatomically or vitally with filtration, or excretion, or both. Something yet remains to be done in the latter field, before the therapeutic action of diuretics become as certain, and as satisfactory, as they now are physiologically, and after all, this is the most practical and important side of the question. In a paper by DR. CHARLES W. PURDY, published in a recent issue of this JOURNAL, some new suggestions were brought forward on this point, in a chemico-pathological relation to the subject, which promise practical results. Dr. Purdy first points out, that anuria of acute nephritis is due for the most part to accumulation of colloid matter (casts) in the convoluted tubes, which blocking up the latter, counteract the blood pressure in the glomerular tufts, preventing filtration and excretion of urine, and thus the reestablishment of diuresis is an impossibility so long as the obstruction remains. He proposes to remedy the difficulty by effecting a chemical solution of the albuminous matters, which block up the renal tubes by rendering the urine alkaline. As albuminous bodies are more or less soluble in alkaline solutions, and as the urine is readily rendered alkaline by administering certain neutral salts, as acetate, or citrate of potash, he claims that the free use of the latter will dissolve and wash out the obstructing matter, reestablishing the flow of urine, and thus relieve the congestion of the glands. As facts supporting the above, he finds that casts are soluble in the course of a few hours in urine rendered slightly alkaline, and he further points out, that casts are rarely found in urine if the latter be alkaline when passed, and lastly, that experience has generally sanctioned the superior efficiency of saline diuretics in acute renal diseases.

As a result of recent investigations into the condition of the circulation in diabetes mellitus, Dr. Purdy finds that high arterial tension is always present in his experience, as shown by the sphygmograph, similar to that which accompanies chronic Bright's disease, and he suggests that many of the symptoms of diabetes which he names, are thus thrown into clearer light in their causal relations.

We can readily understand if conditions of high arterial tension constantly prevail in diabetes mellitus, that the profuse diuresis accompanying that disease is thereby more readily explainable, and moreover, the same condition of the circulation may throw some light on the hitherto obscure pathology of the disease. At any rate, these points are worthy of careful consideration, and their further investigation may lead to practical and important results.

We cannot close this subject without calling attention to the valuable suggestions in Dr. Purdy's paper, for useful physiological work. To what is the high tension in Bright's disease and diabetes to be attributed, and to what is the cardiac hypertrophy of the former due? Are we to accept the theory put forth by Dr. Walshe, and held to a certain extent by Bright, that the hypertrophy is due to the increased resistance of the tissues (capillaries) to the passage of impure blood? Is this increased resistance (if it be present) due to the action of the impure blood on the walls of the capillaries (or possibly on their vaso motor nerves)? Again, by what mechanism does the blood become impure? "Is it by failure of the kidney—by renal inadequacy—or is it a change in the blood either primary in that fluid, or secondary to some toxic agent introduced from without or manufactured within the body?" (*British Medical Journal*, August 29, 1885.) Is it not possible, again, that the high tension in Bright's disease and in diabetes may be due to some action of the altered blood on the heart itself? It certainly seems, in view of the fact that Bright's disease is accompanied by endarteritis, that the vascular complication is in some way brought about by the abnormal state of the blood, and that it is primary to the cardiac affection. Dr. Purdy's paper also suggests an interesting pharmacological question as to the cause of the good effect of subcarbonate of iron in uræmia, and the answer, it seems, must necessily be given by chemistry. The suggestions contained in this paper are quite sufficient to furnish work for physiologists for some time.

THE ETIOLOGY OF ASTHMA

Among the laity it is very customary to denote any form of difficult respiration as asthmatic, and, indeed, members of the profession are often lax in their use of the term Etymologically, asthma signifies labored respiration hence, there is some justification of its employment as synonymous with dyspnœa More over, medical men of olden times appear to have used these two terms interchangeably It would be preferable, if the term asthma could be exchanged for one expressing the true nature of the distressing malady, but the word has too firm a root in our phraseology to be supplanted, and accordingly, certain adjectives are prefixed to distinguish the varieties of dyspnœa in mind The form of suffering to which it is desirable to restrict the term, is known as nervous, bronchial, idiopathic, or spasmodic asthma while the dyspnœa arising from organic disease of intra thoracic viscera is called secondary or symptomatic asthma Occasionally its relation to some particular organ is denoted by such a designation as cardiac asthma It needs no further comment to show how objectionable is this kind of phraseology

Spasmodic asthma, as the term implies, occurs in paroxysms, its characteristic feature being a difficulty of expiration This peculiarity should not be lost sight of, since it distinguishes this form of dyspnœa from that dependent upon structural disease of the heart or lungs In most cases of nervous asthma, the attack is not attended or followed by bronchial catarrh In others the dry râles ultimately give way to moist ones, and the attack terminates in free expectoration as the spasm subsides Careful physical exploration of the chest, either during or after an attack, fails in typical cases to reveal any organic alteration of the lung structure The percussion note is everywhere resonant, respiratory sounds are faint or wholly obscured by sibilant râles The condition is one of temporary distension of the lungs with air In cases of long standing, this temporary dilatation of the air vesicles passes into a chronic vesicular emphysema Asthmatic attacks appear in most sufferers to be occasioned by external agents which irritate the bronchial mucous membrane In some the spasm is induced by internal causes, as, for example, a nasal polypus or an undigested meal Other patients, again, are extremely sensitive to certain climatic or atmospheric conditions Indeed, this last appears to be the case with all asthmatics As a rule, each patient is a law unto himself, and the idiosyncrasies of these victims are as diverse as amusing We know of one gentleman who is so sensitive to the dust of feathers that, as he says, he feels like kicking every goose he sees

Evidently, then, the asthmatic attack is reflex in its origin But what is the real explanation of its phenomena, or, in other words, what is its pathogenesis? This is a subject of much discussion, particularly among the Germans, who, as Von Ziemssen, of Munich, once remarked, are never happier than when they are pulling down some one else's pet theory

As the means of differentiating intra thoracic disease grew apace, after the discovery of auscultation, clinical observers soon discovered that many forms of dyspnœa, which had been classified by older medical writers under the head of asthma, were but examples of dyspnœa due to heart or lung disease Hence the existence of an independent or idiopathic asthma became doubtful in the minds of many, and was at length denied altogether by Rostan, Louis and others They contended that the asthma was the result of bronchial catarrh, emphysema, etc Other able observers however, took up the cudgels in defense of the old theory, that a spasmodic constriction of the smaller bronchi is the cause of the asthmatic attack Experiments were not wanting to sustain this view Williams, and after him Bert, demonstrated that irritation of terminal filaments of the vagus produced contraction of the bronchioles

This theory, which is an old one, is now the one most generally accepted English and American authors adopt this explanation quite generally Not so with our Teutonic confreres They have waged a fierce, if not bloody battle upon this subject Three other theories have been advanced and ably defended The most notable is that of Wintrich, supported by Bamberger and Lehmann These authors base their conclusions upon clinical observation and physical diagnosis rather than post-mortem appearances and experimentation, which they declare give negative results They maintain that the impediment to free expiration in asthma is due to a tonic contraction of the diaphragm Physical examination during an attack discloses a marked and permanent descent of the diaphragm, with evident distension of the lungs by air If bronchial spasm exist at all, it must be secondary, as is the contraction of the respiratory muscles Were bronchial constriction primary, there would be a collapse rather than a dilatation of the lungs Against this theory Biermer contends most strenuously, and asserts that, in consequence of the distension of the alveoli and terminal bronchioles with air, by reason of the bronchial spasm higher up, the diaphragm is forced downward Instead of this muscle remaining fixed and immovable, he has de-true gland yields a secretion free from water," but in the main, the epithelial cells are influenced by special stimuli, of which urea, uric acid, etc., are probably normal ones, and certain salines, notably salts of potash, lithia, soda, etc., are artificial ones. Certain agents both dilate the renal vessels, and stimulate the renal cells, thus exerting a compound action, the most important of which is juniper. Dr. Fox draws the deduction, that to call forth renal activity most efficiently as a whole, it is best to effect a union of diuretics, combining with those which cause vascular fulness, those that stimulate the renal cells, herein securing more thorough depuration of the blood.

So much for the physiological action of diuretics; unfortunately, however, in therapeutical use, this class of agents are proverbially uncertain in their action, "often proving most disappointing where most needed," partly, as might be expected from what has just been said of a few of the many influences that effect, local or general vascular pressure, but more especially as the result of the various pathological changes arising in renal disease, which interfere anatomically or vitally with filtration, or excretion, or both. Something yet remains to be done in the latter field, before the therapeutic action of diuretics become as certain, and as satisfactory, as they now are physiologically, and after all, this is the most practical and important side of the question. In a paper by DR. CHARLES W. PURDY, published in a recent issue of this JOURNAL, some new suggestions were brought forward on this point, in a chemico pathological relation to the subject, which promise practical results. Dr. Purdy first points out, that anuria of acute nephritis is due for the most part to accumulation of colloid matter (casts) in the convoluted tubes, which blocking up the latter, counteract the blood pressure in the glomeruler tufts, preventing filtration and excretion of urine, and thus the reestablishment of diuresis is an impossibility so long as the obstruction remains. He proposes to remedy the difficulty by effecting a chemical solution of the albuminous matters, which block up the renal tubes by rendering the urine alkaline. As albuminous bodies are more or less soluble in alkaline solutions, and as the urine is readily rendered alkaline by administering certain neutral salts, as acetate, or citrate of potash, he claims that the free use of the latter will dissolve and wash out the obstructing matter, reestablishing the flow of urine, and thus relieve the congestion of the glands. As facts supporting the above, he finds that casts are soluble in the course of a few hours in urine rendered slightly alkaline, and he further points out, that casts are rarely found in urine if the latter be alkaline when passed, and lastly, that experience has generally sanctioned the superior efficiency of saline diuretics in acute renal diseases.

As a result of recent investigations into the condition of the circulation in diabetes mellitus, Dr. Purdy finds that high arterial tension is always present in his experience, as shown by the sphygmograph, similar to that which accompanies chronic Bright's disease, and he suggests that many of the symptoms of diabetes which he names, are thus thrown into clearer light in their causal relations.

We can readily understand if conditions of high arterial tension constantly prevail in diabetes mellitus, that the profuse diuresis accompanying that disease is thereby more readily explainable; and moreover, the same condition of the circulation may throw some light on the hitherto obscure pathology of the disease. At any rate, these points are worthy of careful consideration, and their further investigation may lead to practical and important results.

We cannot close this subject without calling attention to the valuable suggestions in Dr. Purdy's paper, for useful physiological work. To what is the high tension in Bright's disease and diabetes to be attributed, and to what is the cardiac hypertrophy of the former due? Are we to accept the theory put forth by Dr. Walshe, and held to a certain extent by Bright, that the hypertrophy is due to the increased resistance of the tissues (capillaries) to the passage of impure blood? Is this increased resistance (if it be present) due to the action of the impure blood on the walls of the capillaries (or possibly on their vaso motor nerves)? Again by what mechanism does the blood become impure? "Is it by failure of the kidney—by renal inadequacy—or is it a change in the blood either primary in that fluid, or secondary to some toxic agent introduced from without or manufactured within the body?" (*British Medical Journal*, August 29, 1885.) Is it not possible, again, that the high tension in Bright's disease and in diabetes may be due to some action of the altered blood on the heart itself? It certainly seems, in view of the fact that Bright's disease is accompanied by endarteritis, that the vascular complication is in some way brought about by the abnormal state of the blood, and that it is primary to the cardiac affection. Dr. Purdy's paper also suggests an interesting pharmacological question as to the cause of the good effect of subcarbonate of iron in uræmia, and the answer, it seems, must necessily be given by chemistry. The suggestions contained in this paper are quite sufficient to furnish work for physiologists for some time.

THE ETIOLOGY OF ASTHMA

Among the laity it is very customary to denote any form of difficult respiration as asthmatic, and, indeed, members of the profession are often lax in their use of the term Etymologically, asthma signifies labored respiration hence, there is some justification of its employment as synonymous with dyspnœa More over, medical men of olden times appear to have used these two terms interchangeably It would be preferable, if the term asthma could be exchanged for one expressing the true nature of the distressing malady, but the word has too firm a root in our phraseology to be supplanted, and accordingly, certain adjectives are prefixed to distinguish the varieties of dyspnœa in mind The form of suffering to which it is desirable to restrict the term, is known as nervous, bronchial, idiopathic, or spasmodic asthma, while the dyspnœa arising from organic disease of intra-thoracic viscera is called secondary or symptomatic asthma Occasionally its relation to some particular organ is denoted by such a designation as cardiac asthma It needs no further comment to show how objectionable is this kind of phraseology

Spasmodic asthma, as the term implies, occurs in paroxysms, its characteristic feature being a difficulty of expiration This peculiarity should not be lost sight of, since it distinguishes this form of dyspnœa from that dependent upon structural disease of the heart or lungs In most cases of nervous asthma, the attack is not attended or followed by bronchial catarrh In others the dry râles ultimately give way to moist ones, and the attack terminates in free expectoration as the spasm subsides Careful physical exploration of the chest, either during or after an attack, fails in typical cases to reveal any organic alteration of the lung structure The percussion note is everywhere resonant, respiratory sounds are faint or wholly obscured by sibilant râles The condition is one of temporary distension of the lungs with air In cases of long standing, this temporary dilatation of the air vesicles passes into a chronic vesicular emphysema Asthmatic attacks appear in most sufferers to be occasioned by external agents which irritate the bronchial mucous membrane In some the spasm is induced by internal causes, as, for example, a nasal polypus or an undigested meal Other patients, again, are extremely sensitive to certain climatic or atmospheric conditions Indeed, this last appears to be the case with all asthmatics As a rule, each patient is a law unto himself, and the idiosyncrasies of these victims are as diverse as amusing We know of one gentleman who is so sensitive to the dust of feathers that, as he says, he feels like kicking every goose he sees

Evidently, then, the asthmatic attack is reflex in its origin But what is the real explanation of its phenomena, or, in other words, what is its pathogenesis? This is a subject of much discussion, particularly among the Germans, who, as Von Ziemssen of Munich, once remarked, are never happier than when they are pulling down some one else's pet theory

As the means of differentiating intra thoracic disease grew apace, after the discovery of auscultation, clinical observers soon discovered that many forms of dyspnœa which had been classified by older medical writers under the head of asthma, were but examples of dyspnœa due to heart or lung disease Hence the existence of an independent or idiopathic asthma became doubtful in the minds of many, and was at length denied altogether by Rostan, Louis and others They contended that the asthma was the result of bronchial catarrh, emphysema, etc Other able observers however, took up the cudgels in defense of the old theory, that a spasmodic constriction of the smaller bronchi is the cause of the asthmatic attack Experiments were not wanting to sustain this view Williams, and after him Bert, demonstrated that irritation of terminal filaments of the vagus produced contraction of the bronchioles

This theory, which is an old one, is now the one most generally accepted English and American authors adopt this explanation quite generally Not so with our Teutonic confreres They have waged a fierce, if not bloody battle upon this subject Three other theories have been advanced and ably defended The most notable is that of Wintrich, supported by Bamberger and Lehmann These authors base their conclusions upon clinical observation and physical diagnosis rather than post-mortem appearances and experimentation, which they declare give negative results They maintain that the impediment to free expiration in asthma is due to a tonic contraction of the diaphragm Physical examination during an attack discloses a marked and permanent descent of the diaphragm, with evident distension of the lungs by air If bronchial spasm exist at all, it must be secondary, as is the contraction of the respiratory muscles Were bronchial constriction primary, there would be a collapse rather than a dilatation of the lungs Against this theory Biermer contends most strenuously, and asserts that, in consequence of the distension of the alveoli and terminal bronchioles with air, by reason of the bronchial spasm higher up, the diaphragm is forced downward Instead of this muscle remaining fixed and immovable, he has detected slight and ineffectual movements of the diaphragm as it struggled to ascend against the cushion of air above The possibility of spasmodic stricture of the bronchi through contraction of muscular filaments, which Reisseissen demonstrated in the walls of the air tubes, Biermer regards as settled indubitably by the investigations of Bert An intermediate ground is occupied by Lebert, who finds an explanation for *asthma in a reflex spasm of first the bronchioles and* then the diaphragm, and perhaps other expiratory muscles

In marked contrast to the foregoing is the view of Weber, according to whom the asthmatic attack is the result of vaso motor disturbance In other words, owing to irritation of the bronchial mucous membrane, a dilatation or paresis of the blood-vessels takes place, producing a fluxionary hyperæmia This obstructs the lumen of the tube and hinders the free escape of air Later on this condition subsides, a copious secretion ensues, and constitutes bronchial catarrh with expectoration This theory is advocated in the main by Storck

Finally, Leyden, now of Berlin, announced his discovery in the sputa of asthmatic patients of minute octahedral crystals imbedded in a mass of granularly degenerated cells He supposes these sharp crystals so irritate the terminal filaments of the vagus within the air tube as to ultimately lead to spasm of the bronchial muscles Such are the various theories offered in explanation of the pathogenesis of bronchial asthma Spastic contraction of the bronchial muscular fibres is the most generally accepted, and is supported by the weightiest evidence

KISSING FROM A MEDICAL STAND POINT

A correspondent in our valued contemporary *Babyhood*, of September, 1885, justly condemns the custom, quite usual with some mothers, of compelling children to kiss people promiscuously The sensibilities of children are very acute, and it is not surprising that they should often strenuously object to promiscuous osculatory exercises It is enough to make even a young child lose all faith in human nature to be compelled to kiss some people And apart from the physical objections to the habit there are moral objections to it If the child objects it is a species of cruelty to compel it to kiss, and if it does not object, it may become so wedded to the habit as possibly to entail serious, moral or physical consequences in after life

We say "physical consequences" with good reason, for besides such a sore accident as rupture of the membrana tympani, which has resulted from a kiss on the ear, loathsome and deadly diseases may be communicated by kissing Any one of the contagious or infectious diseases may be so communicated, and there are certainly numerous cases on record in which diphtheria and scarlatina have been traced very directly to a kiss How is a mother to know but that the person who kisses her child has some specific *affection, that there are specific buccal lesions*, which may be the direct cause of a life time of misery to her child, or an early and horrible death From her stand point, therefore, that compulsory kissing is disagreeable to the child, the correspondent of *Babyhood* is in the right, but, as we have shown, it is doubly wrong, in that it may, after the disagreeable act is finished and perhaps forgotten, entail the most serious consequences

CHOLERA EPIDEMIC —The epidemic which has been prevailing so severely in Spain, is now gradually abating, with a good *prospect that during this season* it will not extend over Europe, or materially beyond its present limits

SOCIETY PROCEEDINGS

AMERICAN DERMATOLOGICAL ASSOCIATION

(*Concluded from page 306*)

FRIDAY, AUGUST 28—THIRD DAY

Dr C Heitzman made some

REMARKS ON ELECTROLYSIS AND OTHER PRACTICAL TOPICS

He spoke very highly of electrolytic epilation For this pupose he uses the Leclanche battery Six cells of this battery has the advantage of steadiness, lack of pain and lack of reaction when applied to the face of the patient He employs a needle devised by Leiter, of Vienna, which permits the depth to which the needle penetrates to be measured He has had good results from electrolytic destruction of dilated blood vessels in the face, less satisfactory results in the treatment of port wine marks, where a *permanent cure is only exceptionable* attainable Sodium æthyl is highly recommended by some, for the destruction of angioma of the face, but it is in no way superior to nitric acid

The speaker maintained, after observing two hundred cases of falling of the hair, caused by seborrhœa, that the method he recommended in 1876, gave fair results This is the application of a ten or twenty per cent ointment of crude oleum rusci in vaseline and parrafine

For the removal of freckles, the Doctor used an ointment *recommended to him* by Wertheim of Vienna The preparation is as follows

℞

Hydrarg ammon muriat , grm ,	3 75
Magist bismuthi , grm ,	3 5
Ungt glycerini, grm ,	30 0
M	

This is to be applied in a thin layer every other night, and in four or six weeks, the result is highly satisfactory As to the permanency of the cure the Doctor was unable to state

In regard to the reappearance of hair after removal by electrolysis, the speaker considered it to be due to the growth of the fine hairs, which was increased by the transferrence to them of the nutrition, which should have gone to the hairs removed

Dr Hyde remarked, that Heitzman had touched upon the important point in the removal of hair by electrolysis The question is not what will the result be at present, but what will it be in the future? The electrolysis produces a hyperæmia which tends to stimulate the growth of the remaining hair He had found the rectified oleum rusci very valuable, and asked what is the test of the crude oil?

Dr Fox said that in the treatment of angioma he had used nitric acid, making the application in the form of small dots, one-fourth to half an inch apart with great advantage In one case in which a nevus occupied half the body, he used this treatment with much success In regard to the return of the hair after electrolysis If the needle is carefully inserted and gentle traction is made on the hair, that hair will not return In some cases there is a constant increase in the downy hairs from some cause, but these are exceptional cases He did not think that the removal of hairs increases the growth of others In one case, that of a young woman with a strong beard, he removed by actual count, eight thousand hairs This process required two or three years Since then it has been necessary to remove only a few dozen hairs

Dr Robinson had employed a similar ointment for the removal of freckles, but its effect was only temporary He thought the growth of the remaining hairs was increased by the removal of a portion

Dr Wigglesworth said, that for the past fifteen years he had used the following ointment, which was almost identical with that mentioned by Dr Heitzman

℞

Hydrarg ammon ,	parts	10

Dr Duhring considered the oil of rusci valuable in seborrhœa of the scalp The objection to it is its disagreeable odor He had also used in chronic seborrhœa of the scalp, a preparation of sulphur, but did not consider it as efficacious as tar

Dr Hardaway had performed the operation of electrolysis for ten or twelve years, probably longer than any other member of the Association He used the irido platinum needle, which has the advantage of being bent, and it is not likely to pass through the follicle wall The moment the follicle is entered, there is an escape of sebum One case, that of a woman with a heavy black beard, has been entirely relieved Electrolysis with a fine needle, affords a method of getting rid of freckles The plan is to dot the needle over the surface covered by the freckle

Dr Heitzman said that the percentage of recurring hairs, is greater in some situations than in others In the submaxillary region, it is greatest The oil of rusci crudum is better than the rectified oil To test it, add alcohol to a small portion of the oil and paint it on the skin If it drys quickly leaving a black mark, it is the crude oil

Dr R W Taylor, of New York, read a paper on

SYPHILITIC RE INFECTION

He first referred to the literature of the subject and gave a brief review of the authentic cases on record, giving the names of the reporters The number of cases previously reported is between thirty and forty To these the speaker added the histories of three more A fourth case has been observed by him, but as the complete history was not prepared, it was not given

Case 1 —A bar keeper, aged 25 years, was first seen in 1868, suffering with gonorrhœa Three years previously had had indolent enlargement of the lymphatic glands in the groins Examination showed the presence of lymphatic enlargement in certain regions Inquiry into the history, showed the existence of a chancre three years before, which had been slow in healing About two months later, he became sick, and suffered with a roseolous eruption, sore throat, falling of the hair, and rheumatic pains, worse at night Under treatment he improved, but afterwards exhibited a papular eruption He was then seen by Dr Van Buren who pronounced the case one of syphilis, and ordered mercurial treatment He recovered after two years, but of his own accord, continued the treatment two years longer He then remained well until the attack of gonorrhœa

In February, 1870, he again appeared, presenting a typical indurated chancre on the cutaneous aspect of the pubes It presented every evidence of a primary infection Later a papular syphilide appeared over the body There were several mucous patches on the pillars of the fauces, and the throat was red and swollen The joints soon became the seat of nocturnal pains The patient also presented a form of syphilitic epididymitis Under mercurial treatment, there was some improvement, but a year later there were some tertiary manifestations By 1874, he seemed very well During the next three years, there were no evidences of syphilis, but he continued the mixed treatment

He was again seen in the fall of 1882, when it was learned that his good health had continued and that he was the father of a healthy child The child was examined and no evidence of hereditary syphilis, detected

Case 2 —Had in June, 1873, a typical indurated chancre, followed by distinct secondary symptoms, which disappeared under treatment He then passed from observation In February, 1874, he presented several ulcero tubercular lesions on the outer aspect of the forearm He then remained under treatment six months In January, 1875, he had spots of thickening of the periosteum of both tibia He was again treated with benefit In June 1876, there was a typical indurated nodule on the prepuce, from which extended indurated lymphatics passing to the inguinal lymphatic glands The incubation of this sore had been about twenty days This was followed by malaise, sore throat, swelling of the post-cervical and epitrochlear glands Over the body and arms there was a fine mottling of light pink color The patient then went to Europe, and was not seen again till March, 1885, when it was learned that the symptoms had been well marked, and that he had been treated for them by several Continental physicians

Case 3, aged 41, had had a typical indurated chancre in 1874 There had been inguinal adenitis, followed by roseola, falling of the hair, and later by severe iritis of the right side He was treated with mercury In February, 1882, he returned with a typical hard chancre In April, he became sick, had rheumatic pains and a mixed eruption of erythematous and papular syphilide In May, inflammation of the iris of the right eye again appeared In 1883, he had a late secondary rash

These cases were reported with the object of throwing some light upon the natural history of second infections of syphilis In all these cases, relapsing indurations were carefully excluded

DR HYDE had seen but two cases of reinfection of syphilis, where he was perfectly sure of the fact

DR H W STELWAGON, of Philadelphia, made some

OBSERVATIONS ON THE OLEATES

In regard to the chemistry and preparation of the various oleates, both as to their manufacture by the direct combination of the acid with the base, and by double decomposition, almost, if not entirely as much can be found in the English translation of Gmelin's "Handbook of Chemistry," published in 1866, as in the writings of the past several years

Of all the oleates, those of mercury zinc, bismuth and lead have a place in the treatment of diseases of the skin, and in view of their costliness, the seeming unavoidable frequency of badly made preparations, the disagreeable oleic acid odor, and the irritation so frequently observed following their use, it is probable that of these four, the mercuric oleate is the only one that promises to retain a permanent value This last is especially valuable in ringworm of the scalp, but for inunctions in the treatment of syphilis, it is of doubtful utility, as it is questionable whether it is absorbed Oleate of copper, which has been so highly recommended for ringworm of the scalp, is not comparable in that affection to oleate of mercury, or to tar and sulphur preparations

DR TILDEN agrees with Dr Stelwagon, that oleates are not useful as ointments

DR WIGGLESWORTH had practically renounced all oleates except the oleates of zinc, lead and mercury, as parasiticides

DR DUHRING said that his experience with these preparations was in accord with that of the reader of the paper He had employed the oleate of copper in varying strengths in thirty or forty cases of ringworm, but it seemed to exert no influence whatever These were, however, obstinate cases Other methods of treatment were afterwards tried, and they were finally cured As to its efficiency in acute forms of ringworm, he was not prepared to speak

DR HEITZMAN had tried the oleate of copper in chronic cases of ringworm, without any result, but in the acute cases, it cures after a time It is not as efficient, however, as the preparation recommended by Dr Taylor, that is, four grains of bichloride of mercury to the ounce of tincture of myrrh

DR FOX said it had been claimed that the oleic acid and animal oils are better absorbed than vaseline and other preparations As a matter of experience, he had found that vaseline makes a better base for the majority of ointments than do the animal oils Vaseline is a most soothing application to the skin

DR HARDAWAY had almost entirely discarded the oleates In some recent cases, the oleate of copper has seemed to be successful, but in chronic cases it *entirely failed*

DR L N DENSLOW then reported

A CASE OF SYPHILITIC APHASIA AND PARAPLEGIA, FOLLOWED BY DEATH, WITH AN ACCOUNT OF THE AUTOPSY

The object of the paper was simply to put on record a case in which an autopsy was obtained in early syphilitic cephalalgia The patient was seen in consultation April 29, 1885 Two months previously, the patient had begun to suffer with severe headache, worse at night There was also a papular eruption He acknowledged the existence of a sore six months previously Iodide of potassium with chloral had been given, two weeks later, the patient was free from pain, but it returned one month afterwards, when the patient stopped taking medicine Iodide of potassium was again given, with the effect of relieving the pain Aphasia and paraplegia then developed, and the patient died four days later, and within nine months of the initial lesion

At the autopsy, the dura mater along the longitudinal sinus was thickened and adherent There were numerous small gummata in the pia mater, situated along the right border of the longitudinal sinus and extended back to the fissure of Sylvius The pia mater exhibited the evidences of simple acute inflammation

OBSTETRICAL SOCIETY OF PHILADELPHIA

Stated Meeting, Thursday, September 3d, 1885

THE PRESIDENT, B F BAER, M D, IN THE CHAIR

DR B F BAER read the following report of a case of

OVARIAN CYSTOMA, COMPLICATED WITH PERITONITIS AND PHLEGMASIA ALBA DOLENS DOUBLE OVARIOTOMY

Mrs M, æt 31, has been a widow nine years She had one child ten years ago, and had enjoyed good health until about three years before I saw her

At that time she observed that her abdomen was increasing in size. This gradually progressed for eighteen months, when she was large enough to attract the attention of her neighbors. After this the growth remained almost stationary and did not affect her general health until the latter part of March of the present year, when she was suddenly seized with pain in the left iliac region. The pain was acute and radiating in character, extending principally down the anterior portion of the left thigh. She attributed the attack to an unusual exertion. Although she made an effort to continue her avocation—that of seamstress—she was compelled to give up and send for her physician, Dr. John R. Haney, of Camden. When Dr. Haney first saw her, her abdomen was very tender over its entire surface, purple from congestion, greatly distended, and tympanitic in its upper but dull in its lower portion. She was suffering great pain and had constant nausea and vomiting, her skin was hot, pulse 120, and temperature 103°. From the history, symptoms, and physical signs elicited, the doctor diagnosticated ovarian cystoma, with supervening peritonitis. He administered quinia per rectum and morphia hypodermatically, together with counter irritation over the abdomen. Within a week the patient appeared to be better, when, through the kindness of Dr. Haney, I first saw her. The tympanites had disappeared and the pain was not so severe, but the abdomen was still very tender on pressure, especially in the left iliac and right umbilical regions, her features were drawn and flushed, and presented an anxious expression, her tongue was dry and heavily coated, pulse quick, and temperature 102°. She lay quietly in the dorsal position, with her thighs flexed. The abdomen was as large as at full term of gestation, and was projecting. It was dull on percussion everywhere except along the line of the colon, and in the epigastrium, and there was evident fluctuation. The uterus was retroverted, not freely mobile, and very tender on pressure on the left side. Above and upon it could be felt the lower border of the circumscribed growth which occupied the abdominal cavity. I fully agreed with Dr. Haney's diagnosis of ovarian cyst complicated by peritonitis. As she seemed to be somewhat better, I advised a continuance of the treatment as previously pursued, with the hope of obviating the necessity of ovariotomy during the unfavorable condition in which she then was. The peritonitis continued to improve slowly, but a new trouble presented itself in a very painful swelling of the left lower extremity. This continued until the limb was greatly increased in size. Its temperature was much higher than that of its fellow, which seemed to be in a normal condition. She now required large doses of morphia to relieve her pain, and she was losing flesh and strength. She still had nausea and took almost no nourishment. Her temperature and pulse had again risen to almost the highest point noted. Both she and her friends were willing and anxious that we should do someteing more radical than simply to wait for a more favorable condition for operating, if we deemed it proper. I believed from the symptoms and physical signs, that the inflammatory action was external to the cyst and not within it, and for that reason decided to wait for a subsidence of the acute symptoms which I rather confidently expected. At the same time I held myself in readiness to operate at once, should the patient not improve or grow worse. The next day she showed signs of slight improvement. Treatment both local and general continued. The acute symptoms gradually subsided to those of a sub acute condition. The temperature had decreased to 101°, pulse 100, but weak. She was still unable to retain food, and was extremely weak. I advised further delay, but she did not improve much after this, her temperature and pulse remaining about the same as that noted above. Her stomach had regained its power to a slight degree to retain and digest liquid food. She had now been confined to her bed more than two months, and her left leg was powerless. There had not been the slightest improvement during the two previous weeks. We therefore decided to remove the tumor.

Operation.—June 19th, 1885, assisted by Drs. J. K. Haney, W. A. Davis, and H. M. Christian and in the presence of a section of the class from the Polyclinic, I made an incision three inches in length down to the peritoneum, and then checked the hæmorrhage with clamp forceps. I next very carefully incised the peritoneum and found, as I had expected, that it was closely united to the cyst wall. These adhesions of cyst to peritoneum were universal, and required careful and patient manipulation to separate them. The parts were exceedingly vascular and hæmorrhage was profuse. After separating it as far as possible I tapped the cyst and allowed the contents, which were semi-liquid and chocolate colored, to drain away. I next closed the puncture made by the trocar, and then completed the separation of the cyst from its adhesions and removed it. As there was a very general and free oozing of blood from the broken vessels, I introduced a number of large flat sponges and spread them over the bleeding surfaces. An assistant now made firm pressure upon the external surface of the abdominal walls, whilst I ligated the pedicle and removed the tumor. The cyst developed in the left ovary and the pedicle was slender, not unusually vascular, and of good length. The right ovary was diseased, contained a number of small cysts, and was double the normal size. I removed it also. Examination now showed that the hœmorrhage had almost ceased, but there were still a number of points from which blood flowed. The peritoneum was intensely injected, and I disliked very much to pick up bleeding points for fear of making the hæmorrhage worse. I therefore reapplied a large flat sponge, and had firm pressure again made from without whilst I proceeded to place the sutures for the closure of the incision. I then removed the sponge and found very little blood upon it. I replaced it by a long, narrow strip of sponge which I allowed to project from the lower angle of the wound, and then again cleansed Douglas's cul-de-sac and other dependent portions of the peritoneal cavity, after which I quickly tied the sutures from above downwards, removing the long sponge through the lower angle of the wound before I had encroachtreated with benefit In June, 1876, there was a typical indurated nodule on the prepuce, from which extended indurated lymphatics passing to the inguinal lymphatic glands The incubation of this sore had been about twenty days This was followed by malaise, sore throat, swelling of the post-cervical and epitrochlear glands Over the body and arms there was a fine mottling of light pink color The patient then went to Europe, and was not seen again till March, 1885, when it was learned that the symptoms had been well marked, and that he had been treated for them by several Continental physicians

Case 3, aged 41, had had a typical indurated chancre in 1874 There had been inguinal adenitis, followed by roseola, falling of the hair, and later by severe iritis of the right side He was treated with mercury In February, 1882, he returned with a typical hard chancre In April, he became sick, had rheumatic pains and a mixed eruption of erythematous and papular syphilide In May, inflammation of the iris of the right eye again appeared In 1883, he had a late secondary rash

Her stomach had regained its power to a slight degree to retain and digest liquid food. She had now been confined to her bed more than two months, and her left leg was powerless. There had not been the slightest improvement during the two previous weeks. We therefore decided to remove the tumor.

Operation.—June 19th, 1885, assisted by Drs. J. K. Haney, W. A. Davis, and H. M. Christian, and in the presence of a section of the class from the Polyclinic, I made an incision three inches in length down to the peritoneum, and then checked the hæmorrhage with clamp forceps. I next very carefully incised the peritoneum and found, as I had expected, that it was closely united to the cyst wall. These adhesions of cyst to peritoneum were universal, and required careful and patient manipulation to separate them. The parts were exceedingly vascular and hæmorrhage was profuse. After separating it as far as possible I tapped the cyst and allowed the contents, which were semi-liquid and chocolate colored, to drain away. I next closed the puncture made by the trocar, and then completed the separation of the cyst from its adhesions and removed it. As there was a very general and free oozing of blood from the broken vessels, I introduced a number of large flat sponges and spread them over the bleeding surfaces. An assistant now made firm pressure upon the external surface of the abdominal walls, whilst I ligated the pedicle and removed the tumor. The cyst developed in the left ovary and the pedicle was slender, not unusually vascular, and of good length. The right ovary was diseased, contained a number of small cysts, and was double the normal size. I removed it also. Examination now showed that the hœmorrhage had almost ceased, but there were still a number of points from which blood flowed. The peritoneum was intensely injected, and I disliked very much to pick up bleeding points for fear of making the hæmorrhage worse. I therefore reapplied a large flat sponge, and had firm pressure again made from without whilst I proceeded to place the sutures for the closure of the incision. I then removed the sponge and found very little blood upon it. I replaced it by a long, narrow strip of sponge which I allowed to project from the lower angle of the wound, and then again cleansed Douglas's cul-de-sac and other dependent portions of the peritoneal cavity, after which I quickly tied the sutures from above downwards, removing the long sponge through the lower angle of the wound before I had encroached so closely upon it as to compress it in its removal It was only slightly stained I quickly applied the external dressing, making an unusual amount of pressure by cotton and bandage The operation was finished, but the patient bore it badly Her extremities were cold and purple, her face livid, and pulse very weak Stimulants hypodermically and the application of external heat, which were begun during the operation, were continued after she was returned to bed She remained in an almost collapsed state for many hours, but gradually reacted and the next morning was in a fair condition Her temperature was lower than it had been for weeks, pulse 112, but weak, stomach quiet, no pain, no tympany She had taken an occasional small piece of ice, but nothing else except the morphia since the operation

June 21st Temperature 102°, pulse 120 Slight pain and tenderness in left iliac region She had been very weak and faint during the night, for which brandy had been administered in repeated small doses The swelling and pain in the limb had diminished, she had not vomited since the operation, and felt hungry Ordered a teaspoonful of milk every second hour

June 22d Comfortable and doing well Temperature 99½°, pulse 90, and strong, slight metrostaxis, passed flatus per rectum Milk increased to a tablespoonful and retained

June 24th Temperature 99°, pulse 85 General condition greatly improved, no pain, no tympany, examined wound and found it united throughout, removed sutures

June 25th Doing well, and is bright and cheerful She took nearly a quart of milk during the last twenty four hours, and digested it

June 30th She has been gradually improving Temperature normal, pulse 95 Bowels moved to day She is taking solid food, and expresses herself as feeling quite well Limb improving She can now move it

July 12th Sat up to day for the first time, the twenty-second day after the operation

August 30th A note received from Dr Haney to day informs me that Miss M is going about attending to some of her duties, but that she has not yet regained her strength fully, and that her limb is still weak

The recovery of the woman under the forlorn circumstances just narrated, is certainly a great triumph for our art, but the case serves a better purpose in forcibly illustrating the danger of deferring operative interference in ovarian cystoma, simply because the patient is comfortable, and suffering no inconvenience from the presence of the tumor The subject of an ovarian tumor is in constant danger of injury from slight causes, which may produce such changes in the tumor, as to render what might have been a simple and safe operation, one of extreme hazard This had been a simple, slow growing cyst, and had not markedly affected the health during its three years of existence, yet it suddenly became inflamed, and the patient narrowly escaped death as a result The case furnishes a strong argument in favor of operation as soon as the disease is diagnosticated Of course there are qualifications and each case must be decided on its own merits, but the rule that an ovarian tumor should be removed as soon as it is known to exist is the only safe one to follow

As a striking contrast to the case just related, and to show the value of the principle enunciated, I will report the following case of

POLYCYSTIC OVARIAN TUMOR, DOUBLE OVARIOTOMY

A K was sent to me August 5th, 1885 She was 19 years of age, single Puberty was established at sixteen, and she had menstruated regularly until six months previously She then without cause, so far as she knew began to flow more freely at her periods and they continued longer About the same time she noticed a small lump in the right iliac region This increased in size so that soon the entire hypogastrium was distended, and when I first saw her she was as large as at the eighth month of gestation Her face showed marked signs of emaciation and pallor, and the drawn, anxious expression of ovarian cystic disease She was then having a profuse metrorrhagia every two weeks She had not suffered any pain, and up to within a few weeks very little inconvenience except from the frequent metrorrhagia

During the last month, however, her health had been failing, she had lost flesh, had a weak languid feeling, and suffered much from the weight of the growth Physical examination in the dorsal position revealed a projecting slightly irregular abdomen, larger on the right side, dull on percussion over the entire anterior surface, but resonant along the line of the colon Palpation showed imperfect fluctuation and several firm irregular masses within the abdominal cavity The vagina was virginal the cervix uteri was pointing forwards, the body of the uterus retroverted, the whole organ enlarged and soft It was only slightly movable independently of the tumor The sound gave a measurement of three inches I diagnosticated polycystic disease of the right ovary, and advised immediate operation Six days afterwards, on August 11th, she entered my private hospital, and on the 13th I operated with the assistance of Drs H M Christian and J N Richards I made an incision two and a half inches in length, and came upon the surface of the tumor, which presented the white glistening nacreous appearance, especially common to thick walled polycysts Tapped with Hodge's trocar The contents were so thick, that they flowed very slowly, and it was necessary to puncture several smaller cysts, which was done without removing the instrument Even then the mass did not collapse much, because of a large number of young or child cysts After closing the puncture, I enlarged the incision to three inches, but I had considerable difficulty in removing the tumor It was necessary to make firm traction with rotatory movements whilst Dr Christian exerted a counter force and pressure through the abdominal walls Fully ten minutes were occupied in delivering the tumor after it was tapped, but I was rewarded with an incision that looked so small that it seemed almost incredible that this large mass had passed through it There had not been a single adhesion, but the pedicle was short, thick and vascular. I tied it with Tait's Staffordshire knot, cut the tumor away and dropped the stump. The tissues of the left ovary were found to be entirely disorganized and degenerated into a cyst as large as a walnut. This I also removed. The uterus presented a very vascular appearance and was somewhat enlarged. After assuring myself that the peritoneal cavity was entirely free from any foreign matter, I closed the incision, dressed the wound, and returned the patient to bed. Temp. normal, pulse, 96°, no pain but as she felt a little sore and restless ¼ grain of morphine was given hypodermically, small pieces of ice for thirst. 14th, 8 A.M., temp. 99°, pulse 84, had passed a good night. At 1 P.M., 26 hours after the operation, milk in teaspoonful doses was allowed, water when she desired it. 15th, metrostaxis began this morning. 18th, union complete, renewed sutures. Her recovery was uninterrupted. She sat up for a few minutes on the 11th day, and went home, eight miles in a carriage on the 18th day after the operation. To-day she sent a request to be permitted to go out, because she is feeling so well. Certainly nothing could have been gained by procrastination in this case.

Dr. Goodell congratulated Dr. Baer on the good results obtained in such a serious case as that first reported. Great care in the asepsis of these cases should be observed. In one of his cases of septicæmia before the operation, after complete union had been secured, the stitches had been removed, and after the patient was up, an abscess was observed, forming in the line of union and was very persistent. Finally, after careful search, a ligature which had been tied around the pedicle of one of the ovarian cysts was found and removed. Subsequently the other appeared, and after its removal the abscess healed. He did not like to remove the stitches so early as Dr. Baer removed them, and he reminded Dr. Baer of a case in which he had assisted Dr. Goodell. The operation was performed on December 5th. Convalescence was rapid, and the patient was so impatient to be home on Christmas that she could not be restrained, and on the 19th day after the operation she took the cars for home. The train was derailed, and the jolting caused the cicatrix to open. The physician who was called in closed it immediately and the patient recovered. In another case a cough caused the wound to burst open and reveal the bowels after the stitches had been removed. This patient also recovered. For these reasons he never removed the patient before the eighth day and not until the bowels had been opened. He inquired of Dr. Baer his method of closing the opening in the cyst after it had been tapped preparatory to its removal from the abdominal cavity. Does he employ pressure forceps? What method of dressing the abdominal wound?

Dr. Baer replied that he closes the cyst puncture with Well's clamp forceps when the cyst wall is strong enough. In some cases he stitches up the opening, or ties a string below it when the cyst walls are loose and soft. He closes the external wound, as he had been taught by Dr. Goodell, with silk sutures and dresses it with salicylated or absorbent cotton, adhesive strips to hold the cotton in place and take the strain off from the stitches, and over all a bandage. He removes the sutures on the fourth or fifth day in order to avoid the danger of pus forming in the suture tracks, as has sometimes occurred when he has allowed them to remain as long as eight days.

FOREIGN CORRESPONDENCE

LETTER FROM PARIS

(FROM OUR OWN CORRESPONDENT.)

The Principles of Listerism—Experiments with Trichinosed Meat—Intra Uterine Injections of Perchloride of Iron Solutions in Metrorrhagia—A Plaster Model of the Brain—Disposal of Debris of Cadavers.

In his opening address in the course of clinical surgery at the Necker Hospital, Professor Le Fort chose for his subject the principles of Listerism, or the modern system of antiseptic treatment in surgery, which he has just published under the title of "Les Pansements et la Mortalité." After examining in this essay the results of treatment of wounds and of the puerperal state from the earlier part of this century, he concludes that a large mortality used to be looked upon as inevitable, and supposed to be brought about by atmospheric influences, or by some agent whose nature was undefinable. The author believes that he was the first to indicate clearly that contagion was the sole cause of the difference of mortality in hospital and in private practice, and that consequently, surgical and other dressings ought to have for their object the destruction of germs which might be the starting point of infection. Professor Lister's doctrine "applies only to recent wounds, and does not take into consideration contagion but seeks to prevent suppuration in the destruction, by means of carbolic acid, of the fermentation-germs contained in the air."

Prof. Le Fort attributes the various infections to *contagion*, and he regards the agent of this contagion "as a contagion germ of unknown nature (but possibly a special microbe), developing primarily, if not spontaneously, under various influences in a patient who has been subjected to operation, and which emphatically requires us to guard against carrying the active principle of contagion into a wound." He considers that the doctrine of M. Pasteur, so justified in its application to fermentation and putrefaction, applies to surgery, when it is used to explain alteration of normal or pathological liquids by contact with the air. The alteration of these liquids by the ferment changes can give rise to septic poisoning, but ferments cannot create morbid entities like pyæmia, erysipelas, typhoid fever, cholera, scarlatina, etc., which are characterized by a special contagion-germ transmissible in each case. While ridiculing the minutiæ of the Listerian principles and practice, he recognizes that the adoption of the Listerian antiseptic dressing has been attended with a notable reduction of mortality in hospitals, and that many operations have been made much less dangerous In fact, in trying to oppose the fermentation-germ, the dressing of Lister has opposed the contagion-germ The good results thus obtained are, according to Le Fort, due to the principles he has himself adopted for a long time as a consequence of his belief in contagion-germs Thus it may be seen that, while both these eminent surgeons have been working with the same materials, but on essentially different theories, they have arrived at the same satisfactory results Prof Le Fort, however, accords to Sir Joseph Lister the credit of having introduced into surgical practice his special mode of dressing, which has proved such a boon to wounded patients

A great deal has been said and written on the deleterious influence of trichinosed meat used as food, but according to M Duprez, Veterinary Inspector of the butchers' shops in Paris, this is not so great as has been claimed In a note to the Biological Society of Paris, he gives an account of some experiments performed by him with trichinosed meat Two series of rats were fed with American pork, containing trichinæ One set of rats was fed daily with a mixture composed of 10 grammes of trichinosed pork, 20 grammes of bread and a little water, the second set got 15 grammes of the pork with a little water, but no bread At the end of three weeks, no accident was observed, with the exception of a slight diarrhœa Fragments of muscles taken from the animals in a living state, contained no trace whatever of trichinæ

A great many gynecologists employ intra uterine injections of solutions of the perchloride of iron in cases of metrorrhagia, which, it is true, might stop the hæmorrhage, but Dr Sirédey, of the Lariboisière Hospital, absolutely condemns the practice for the following reasons The perchloride of iron nearly always determines a violent inflammation in the parts with which it is in contact, extending even to sloughing Dr Sirédey, therefore, prefers to have recourse to the other means usually employed in such cases, such as the tamponment, subcutaneous injections of ergotine, when one is sure that it is not a case of threatening abortion He also employs cauterizations of the mucous membrane of the uterus with the nitrate of silver melted on the extremity of the uterine caustic holder, which is much easier of application than the injections of the perchloride of iron It rapidly stops the bleeding, without having any of the inconveniences of the iron, and may be employed in all cases of metrorrhagia which are not dependent on fibroma or cancer

Dr Luys has presented to the Paris Academy of Medicine a plaster model of a human brain made under his directions It is nearly four times larger than the natural size, nevertheless, it is an exact reproduction of the human brain, being enlarged from an impression taken from nature It is the first of its kind that has been made in France There is a plaster model of a human brain at the Anthropological Society of Paris, made according to the directions of Broca, but which is the synthesis of different cerebral regions copied from different subjects

Until recently, the *debris* of corpses used for dissections have been buried in the cemetery of Montparnasse only A decree just published by the Prefect of the Seine authorizes them to be incinerated in a special apparatus established in the Père la Chaise, or to be buried in one of the other cemeteries of Paris A B

DOMESTIC CORRESPONDENCE

THE INTERNATIONAL MEDICAL CONGRESS

To the Editor of the Journal

Dear Sir —In the discussion by various medical journals, of the propriety of the action of the American Medical Association in arranging for the meeting of the Medical Congress at Washington in 1887 much has been said, and with an evidently malicious animus on the part of some to discredit the action of the Association They claim that in all instances the Congress has been convened only by the action of the *profession* of the country where it meets A brief reference to *facts*, will perhaps place the position of the invitation clearly before your readers

At the annual meeting of the American Medical Association held at Washington, May 6, 1884, "at which there were more than 1,200 regularly registered members (of the profession) present,"[1] Dr Austin Flint, President, in his official address, stated the origin of the Association and the objects for which it was formed in 1847, these being for "the protection of their interests, for the maintenance of their honor and respectability, for the advancement of their knowledge and the extension of their usefulness, for exciting and encouraging emulation and concert of action in the profession, and for facilitating and fostering friendly intercourse between those who were engaged in it" He fully showed how, during thirty-eight years, these objects had been faithfully carried out, to the great benefit of medical men He then subsequently said "Our Association, both by precept and example, has aimed to facilitate and foster friendly intercourse between those engaged in the practice of medicine, and these should not be limited to our own country As the means of union for these objects of the medical *profession* of all countries, the International Medical Congress claims a warm interest, and it would prove, as I doubt not, a source of great gratification to the *profession* of our country, if the meeting of the Congress in 1887 were to be held in the United States, and I suggest the propriety of action to be taken *now*, with reference to this desirable end *Inasmuch as the invitation should be in behalf of the profession of the whole country and not of any particular section, it appropriately should come from the American Medical Association* If the suggestion be favorably received, it seems to me advisable that a Committee be appointed *with instructions* to carry an invitation *from this Association*, through *its* delegates, to the Congress at Copenhagen The Committee may also be empowered to designate the time and place of meeting of the Congress in 1887, and to take such other preliminary steps as may appear to the Committee to be requisite My suggestion in regard to the International Congress is not made solely on my own responsibility, but at the instance *of several, well known for their active interest in the welfare of the American medical profession*" The only one of these specially named was the late Professor Samuel D Gross The origin of the invitation is thus clearly established, it was an invitation by 1,200 members of the medical profession in the United States, through a committee of delegates from the American Medical Association, to the Congress at Copenhagen

[2] The italics are mine

I have no wish to discuss the action of the Committee subsequently appointed as "delegates to the Congress," with a special object Their sole status in the Congress arose from the authority given them by *the Association* By all parliamentary law, as well as courtesy to those who entrusted them with their mission, their duty was to report their action to the next meeting of the Association at New Orleans When the Association accepted their report, they were *ipso facto* discharged, and further action on the subject rested with the Association The action taken at New Orleans by the Association was correct in parliamentary law and approved by high parliamentary authority The subsequent action of the Committee to whom the subject *was recommitted*, can only be correctly known when its official report is made at St Louis, and all discussion of their action now is improper, because based on rumor and not on facts The Association alone can give a value to the acts of the Committee by accepting their report

AN OLD MEMBER OF THE MEDICAL PROFESSION

BOOK REVIEWS

A PRACTICAL TREATISE ON DISEASES OF THE KIDNEYS, AND URINARY DERANGEMENTS By CHARLES HENRY RALFE, M A, M D (Cantab) Fellow of the Royal College of Physicians, London, Assistant Physician to the London Hospital Formerly Senior Visiting Physician to the Seamen's Hospital, Greenwich, etc, etc London 8vo, pp 572 H K Lewis & Co, 1885 Philadelphia P Blakiston, Son & Co

The first chapter of this book deals with the general symptomatology of renal diseases, as manifested through derangements of the nervous, vascular, respiratory, digestive, cutaneous and urinary systems

The second chapter is devoted to the clinical examination of the urine, which the author's ready clinical knowledge enables him to render extremely practical, and clear in detail Something over a hundred pages are devoted to this very important subject

The several forms of nephritis are next considered in detail With regard to the nephritis of pregnancy, which heretofore has generally been considered as arising mostly during the last months of gestation, the author writes "it would be more accurate, however, to state, that it is rarely met with before the end of the third month, and, that it hardly ever develops after the seventh month" With regard also to the generally accepted statement, that primiparæ are more liable to nephritis than women who have already born children, the author says "this statement, however, requires modification, and it should rather be, that women who have not been the subject of nephritis in their first pregnancy, are less liable to the disease in subsequent pregnancies, and that the risk is diminished with successive pregnancies" These points it will be observed, are important as bearing on the cause of nephritis of pregnancy, which just now, is the subject of more or less dispute among authors In the treatment of ordinary cases of acute nephritis, the author advises the avoidance of the more active eliminative measures, such as cathartics, diaphoretics, and diuretics, limiting these for the most part to cases attended with suppression of urine, and acute uræmia In these last conditions also, absolute non-nitrogenous diet is advised for at least two days after which, slight relaxation of this rigid dietetic requirement is permitted, if there is manifest improvement The milk treatment, which has of late become revived, and perhaps we may say, is so justly popular, the author points out should not be employed in acute stages of nephritis, as in such conditions, he has even observed harmful results follow its use In sub acute, or chronic nephritis, however, he has found its employment often highly beneficial, fequently causing rapid disappearance of albuminuria, and other threatening symptoms

Suppurative inflammations of the kidneys, pelves, ureters, and surrounding tissues, are next considered individually Among these, of special interest will be found the section on Pyelo-Nephrosis, (surgical kidney) "catheter fever" of Sir Andrew Clark, or what is perhaps most appropriately termed by Dickinson, "uriseptic kidney" The author advises, when as is usually the case in this affection, the urine is ammoniacally putrescent, the internal administration of quinine, and boracic acid, "the latter having the advantage possessed by few other antiseptic remedies, of passing unchanged through the kidneys, it therefore acts upon the whole urinary tract" The author also suggests as a local measure, washing out the bladder with antiseptic solutions in such cases, while we believe that this fever is more often precipitated by the hyperæmia, consequent on reflex irritation produced by the introduction of instruments into the bladder, than by the actual introduction of septic matter in catheterizing, etc, yet we agree with the author that after the mischief is once lighted up, "there is less risk in completely emptying the bladder, than in allowing foul urine to accumulate" In a recent case in point, we attribute its successful issue very largely to washing out the bladder twice daily with an antiseptic solution

Degenerations, new growths, and parasites of the kidneys, constitute the subjects of the next three chapters

Diabetes insipidus and mellitus are considered at length in chapter nine In the medicinal treatment of diabetes mellitus, the author seems to rely more operations have been made much less dangerous. In fact, in trying to oppose the fermentation-germ, the dressing of Lister has opposed the contagion-germ. The good results thus obtained are, according to Le Fort, due to the principles he has himself adopted for a long time as a consequence of his belief in contagion-germs. Thus it may be seen that, while both these eminent surgeons have been working with the same materials, but on essentially different theories, they have arrived at the same satisfactory results. Prof. Le Fort, however, accords to Sir Joseph Lister the credit of having introduced into surgical practice his special mode of dressing, which has proved such a boon to wounded patients.

A great deal has been said and written on the deleterious influence of trichinosed meat used as food, but according to M. Duprez, Veterinary Inspector of the butchers' shops in Paris, this is not so great as has been claimed. In a note to the Biological Society of Paris, he gives an account of some experiments performed by him with trichinosed meat. Two series of rats were fed with American pork, containing trichinæ. One set of rats was fed daily with a mixture composed of 10 grammes of trichinosed pork, 20 grammes of bread and a little water, the second set got 15 grammes of the pork with a little water, but no bread. At the end of three weeks, no accident was observed, with the exception of a slight diarrhœa. Fragments of muscles taken from the animals in a living state, contained no trace whatever of trichinæ.

A great many gynecologists employ intra-uterine injections of solutions of the perchloride of iron in cases of metrorrhagia, which, it is true, might stop the hæmorrhage, but Dr. Siredey, of the Lariboisière Hospital, absolutely condemns the practice for the following reasons: The perchloride of iron nearly always determines a violent inflammation in the parts with which it is in contact, extending even to sloughing. Dr. Sirédey, therefore, prefers to have recourse to the other means usually employed in such cases, such as the tamponment, subcutaneous injections of ergotine, when one is sure that it is not a case of threatening abortion. He also employs cauterizations of the mucous membrane of the uterus with the nitrate of silver melted on the extremity of the uterine caustic holder, which is much easier of application than the injections of the perchloride of iron. It rapidly stops the bleeding, without having any of the inconveniences of the iron, and may be employed in all cases of metrorrhagia which are not dependent on fibroma or cancer.

Dr. Luys has presented to the Paris Academy of Medicine a plaster model of a human brain made under his directions. It is nearly four times larger than the natural size, nevertheless, it is an exact reproduction of the human brain, being enlarged from an impression taken from nature. It is the first of its kind that has been made in France. There is a plaster model of a human brain at the Anthropological Society of Paris, made according to the directions of Broca, but which is the synthesis of different cerebral regions copied from different subjects.

Until recently, the *debris* of corpses used for dissections have been buried in the cemetery of Montparnasse only. A decree just published by the Prefect of the Seine authorizes them to be incinerated in a special apparatus established in the Père la Chaise, or to be buried in one of the other cemeteries of Paris. AN OLD MEMBER OF THE MEDICAL PROFESSION
Philadelphia, Sept 9, 1885

BOOK REVIEWS

A PRACTICAL TREATISE ON DISEASES OF THE KIDNEYS, AND URINARY DERANGEMENTS By CHARLES HENRY RALFE, M A, M D (Cantab) Fellow of the Royal College of Physicians, London, Assistant Physician to the London Hospital Formerly Senior Visiting Physician to the Seamen's Hospital, Greenwich, etc, etc London 8vo, pp 572 H K Lewis & Co, 1885 Philadelphia P Blakiston, Son & Co

The first chapter of this book deals with the general symptomatology of renal diseases, as manifested through derangements of the nervous, vascular, respiratory, digestive, cutaneous and urinary systems

The second chapter is devoted to the clinical examination of the urine, which the author's ready clinical knowledge enables him to render extremely practical, and clear in detail Something over a hundred pages are devoted to this very important subject

The several forms of nephritis are next considered in detail With regard to the nephritis of pregnancy, which heretofore has generally been considered as arising mostly during the last months of gestation, the author writes "it would be more accurate, however, to state, that it is rarely met with before the end of the third month, and, that it hardly ever develops after the seventh month" With regard also to the generally accepted statement, that primiparæ are more liable to nephritis than women who have already born children, the author says "this statement, however, requires modification, and it should rather be, that women who have not been the subject of nephritis in their first pregnancy, are less liable to the disease in subsequent pregnancies, and that the risk is diminished with successive pregnancies" These points it will be observed, are important as bearing on the cause of nephritis of pregnancy, which just now, is the subject of more or less dispute among authors In the treatment of ordinary cases of acute nephritis, the author advises the avoidance of the more active eliminative measures, such as cathartics, diaphoretics, and diuretics, limiting these for the most part to cases attended with suppression of urine, and acute uræmia In these last conditions also, absolute non-nitrogenous diet is advised for at least two days, after which, slight relaxation of this rigid dietetic requirement is permitted, if there is manifest improvement The milk treatment, which has of late become revived, and perhaps we may say, is so justly popular, the author points out should not be employed in acute stages of nephritis as in such conditions, he has even observed harmful results follow its use In sub acute, or chronic nephritis, however, he has found its employment often highly beneficial, fequently causing rapid disappearance of albuminuria, and other threatening symptoms

Suppurative inflammations of the kidneys, pelves, ureters, and surrounding tissues, are next considered individually Among these, of special interest will be found the section on Pyelo Nephrosis, (surgical kidney) "catheter fever" of Sir Andrew Clark, or what is perhaps most appropriately termed by Dickinson, "uriseptic kidney" The author advises, when as is usually the case in this affection, the urine is ammoniacally putrescent, the internal administration of quinine, and boracic acid, "the latter having the advantage possessed by few other antiseptic remedies, of passing unchanged through the kidneys, it therefore acts upon the whole urinary tract" The author also suggests as a local measure, washing out the bladder with antiseptic solutions in such cases, while we believe that this fever is more often precipitated by the hyperæmia, consequent on reflex irritation produced by the introduction of instruments into the bladder, than by the actual introduction of septic matter in catheterizing, etc, yet we agree with the author that after the mischief is once lighted up, "there is less risk in completely emptying the bladder, than in allowing foul urine to accumulate" In a recent case in point, we attribute its successful issue very largely to washing out the bladder twice daily with an antiseptic solution

Degenerations, new growths, and parasites of the kidneys, constitute the subjects of the next three chapters

Diabetes insipidus and mellitus are considered at length in chapter nine In the medicinal treatment of diabetes mellitus, the author seems to rely more largely upon opium Vapor baths are highly commended also in these cases Thus the author writes with regard to the latter, "It is strange that such an efficacious aid to our treatment, should have been persistently overlooked by recent English writers on the subject" The preparations of arsenic, including the bromide, which has attained some popularity of late in America, is not spoken of with much favor, save in cases complicated with malaria

Stone and gravel are systematically considered in the succeeding chapter The author holds that the nuclei of renal calculi, take their origin in the renal cells of the convoluted tubes, by retention within them of uric acid, oxalate of lime, or phosphate of lime "owing to some vital impairment of their (the cells) function," and that this is the origin of all urinary calculi, except those formed upon some foreign substance introduced from without into the bladder

Functional albuminuria, peptonuria, and hæmoglobinuria, comprise an interesting chapter at the close of the work Of late an impression has gained some belief, that albumin occurs quite often in the urine of perfectly healthy persons, indeed, some authors, notably Senator, claim that normal urine is always "feebly albuminous" Certain experiments of late conducted on a large scale, notably those of Capitan and Chateaubourg, would seem to show that albumin is present in the urine of a majority of healthy people The author, however, does not believe in the existence of so called physiological albuminuria In his own experience, albumin has not been found in to exceed three per cent of the cases met with in applications for life insurance He points out that the discrepancy between the results obtained by different observers is probably due to the use of imperfectly corrected tests Thus, the experiments of Capitan and Chateaubourg were conducted by means of the potassio mercuric iodide test, which, the author correctly says, precipitates many other bodies besides albumin Thus, in the case of 94 soldiers experimented upon by Chateaubourg, the above test "gave a precipitate with 76 urines, whilst heat only once proved the presence of albumin"

The occasional appearance of albumin in the urine of those whose kidneys are not organically damaged, the author concedes, and discusses these under such causes as derangements of digestion, disturbed innervation, altered conditions of the blood, etc, etc An appendix is added, containing rules for quantitative analysis for urea, hippuric acid, phosphoric acid, sulphuric acid, hydrochloric acid, albumin, and sugar in the urine, and also one containing a diet list for diabetics

It will thus be noted that the scope of the work is quite extensive, including practically all renal diseases, functional and organic, the language is clear and concise, the text unincumbered by *theoretical* discussions, while the whole matter is thoroughly up with present knowledge on the subject, admirably adapting it for the use of students Footnotes are entirely dispensed with, references being inserted in their appropriate places in the text in parenthesis, and we should be glad to see this excellent example more generally followed, especially in text-books

The author is already favorably known in America as the writer of a work on "Clinical Chemistry," and also one on "Morbid Conditions of the Urine Depending on Derangements of Digestion," and the present volume more than sustains the high reputation gained by its predecessors We congratulate Dr Ralfe on having written one of the best text books on renal diseases to date, if, indeed, not the best

MISCELLANEOUS

NEW YORK STATE MEDICAL ASSOCIATION—FIFTH DISTRICT BRANCH —The first *annual* meeting of the Fifth District Branch will be held in Brooklyn, on Tuesday, October 13th, 1885 There will be a morning and afternoon session

All Fellows desiring to contribute to the meeting, either by reading papers, notes or communications, or by exhibiting specimens, are respectfully invited to notify the Secretary, E H Squib, M D, 36 Doughty Street, Brooklyn, to that effect at their earliest convenience

REVACCINATION IN GERMANY —The commission appointed by the German Government last fall on the subject of vaccination and its effects as a preventive of small pox, report that since 1874, when revaccination was strictly enforced (it had been partially in vogue for some years before), not one death has occurred in the German army, while in those of Austria and France, where revaccination is not enforced, and where the soldiers mix with a population but imperfectly vaccinated, the mortality has been high, ranging from ten to twenty five per hundred thousand in the Austrian, and from seventeen to twenty nine in the French Comparison of the ravages of the disease in the large cities of Europe was also made, in all cases the results being largely in favor of Germany These facts are held to show that revaccination confers almost complete immunity from small pox, and justify the enforcement of the ordinance by the German health authorities

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT U S ARMY FROM SEPTEMBER 5 1885 TO SEPTEMBER 11 1885

McKee J C, Major and Surgeon, sick leave still further extended three months, on surgeon's certificate of disability (S O 204, A G O, Sept 7 1885)

Patzki, J H, Capt and Asst Surgeon, assigned to duty as post surgeon, Jackson Barracks, New Orleans, La (S O 192, Dept of the East, Sept 8, 1885)

Kane, Jno J, upon expiration of his present leave of absence to be relieved from duty at Willet's Point, N Y H, and to report to the commanding general Dept of Texas for assignment to duty (S O 201, A G O, Sept 3 1885)

Richards, Chas, Capt and Asst Surgeon, to be relieved from duty in Dept of the East, and to report to the commanding officer Willet's Point, N Y, for duty at that station (S O 201, C S, A G O

Polhemus, A S, First Lieutenant and Asst Surgeon, when relieved at Ft McDermit, Nev, assigned to temporary duty at Presidio of San Francisco, Cal (S O 87, C S, Dept of California)

Kendall, Wm P, First Lieutenant and Asst Surgeon, relieved from duty at Presidio of San Francisco, Cal, and assigned to duty as post surgeon at Ft McDermit, Nev, relieving Asst Surgeon Polhemus S O 87, Dept of Calif, Aug 31, 1885)

THE SURGICAL TREATMENT OF CYSTS OF THE PANCREAS[1]

BY N SENN, M D,
OF MILWAUKEE WIS

TOPOGRAPHICAL ANATOMY

For a correct interpretation of the signs and symptoms of cysts of the pancreas, and for an accurate understanding of the relations of this organ to surrounding parts in their surgical treatment, it becomes necessary to allude briefly to the topographical anatomy of the pancreas The pancreas is a tongue shaped gland placed transversely in the abdomen, at a point opposite the first lumbar vertebra behind the stomach, reaching from the hilus of the spleen to the concavity of the duodenum Its right end, termed the head, is embraced by the curvature of the duodenum, whilst its left or caudal extremity is in contact with the spleen After opening the abdominal cavity in cadavers, it can be distinctly felt as a firm body through the walls of the stomach The organ is made accessible and exposed to sight by cutting the ligamentum gastro colicum transversely, and by pushing the stomach upwards and the transverse colon downwards In the saccus epiploicus, which has now been opened, the gland is seen in front of the large vessels It presents three surfaces for examination The anterior surface, somewhat concave, is in contact with the stomach throughout its entire extent, but separated from it by a covering from the omental bursa which renders the surface smooth and well adapted for the free movements of the stomach The posterior surface is separated from the spine by the vena cava, aorta, the superior mesenteric artery, and vein, the pillars of the diaphragm, and towards the liver, the vena porta, as well as numerous lymphatic vessels and glands, all of which are firmly connected with this surface, and the spine, by connective tissue To the left of the vertebral column it is attached in the same manner to the left suprarenal capsule, kidney, and renal vessels The superior mesenteric artery and vein are embraced by the substance of the gland, so as sometimes to enclose these vessels in a complete canal The inferior surface is narrow and directed toward the transverse colon, it rests at one end on the junction of the duodenum and jejunum, at the left end on the extremity of the transverse colon The intervening middle portion of the inferior surface has a special peritoneal covering derived from the lower layer of the mesocolon *Along the posterior surface and upper border of the gland are placed the splenic artery and vein, both pursuing a tortuous course from right to left* The cœliac axis is above the pancreas The common bile duct is in close relation to the head of the gland, passing down along its posterior surface, and is generally received into a groove or canal in its substance

The common pancreatic duct, or canal of Wirsung, is widest near its entrance into the duodenum, where it is from one twelfth to one ninth of an inch in diameter Before its termination it unites with the common bile duct in the wall of the intestine, at the junction of the second and third portions of the duodenum, between three and four inches below the pyloric orifice of the stomach The lower extremity of the head, where it curves behind the mesenteric artery and vein, is sometimes marked off from the rest, and is then called the *lesser pancreas*, with a special duct which joins the common duct in the substance of the head of the pancreas The pancreas receives its blood supply from the superior and inferior pancreatico-duodenal branches of the hepatic and superior mesenteric arteries The venous return takes place through the splenic and superior mesenteric veins The nerves are derived from the solar plexus

ACCESSORY PANCREAS

The pancreas, like many other glandular organs, sometimes presents rudimentary duplicities, and it is necessary to call attention to this fact for the purpose of considering the possibility of the origin of a pancreatic cyst from one of these appendages Rokitansky[1] mentions, as an exceedingly rare occurrence, duplicity of the pancreas and excessive development of accessory appendages A frequent variety is represented by the head of the gland—the pancreas minus—the duct of which usually terminates in the common duct, but sometimes as was first ascertained by Winslow it takes an independent course and empties into the duodenum about one to one and one half inches below the opening of the common duct More recently, Hyrtl has called attention to an accessory pancreas consisting of a few isolated acini of the gland behind the superior mesenteric artery and vein Klob has described an accessory pancreas distant and distinct from the normal organ, which was found between the muscular layers of the stomach, about the middle of the great curvature On another occasion he found a similar organ in the posterior wall of the jejunum, near its upper termination In both instances, the true glandular structure of these bodies was confirmed by microscopical examinations

[1] Nebenpancreas in der Darmwand Virchow's Archiv vol xxi, p 369

Zenker met with six instances of supernumerary pancreas The accessory organ was invariably in the walls of the intestine, three times in the highest convolution of the jejunum, twice near the duodenum, and in the last case in the upper portion of this portion of the intestinal tract In size the glands varied from a lentil to a silver dollar They were situated between the intestinal tunics, and presented a prominence on the serous surface Klob found no excretory duct in his specimens Zenker detected the terminal end upon the mucous surface of the intestinal canal in the shape of a slightly raised papilla which could be seen with the naked eye or by means of a magnifying glass The presence of pancreatic juice in the glands was also determined In all instances, the gland proper was found in its normal location and of natural size All patients were adults Like other accessory organs, the supernumerary pancreatic glands owe their origin to embryonal deposits of gland tissue Although, as yet, no instance has been observed of cystic formation from an accessory pancreas, there is no reason why such an occurrence should not take place, for the same reasons and in the same manner as has been observed in cases of cysts from supernumerary thyroid glands

PATHOLOGY AND MORBID ANATOMY

Cysts in the pancreas always result from retention of the secretion, and subsequent dilatation of the secretory duct, or, in case of laceration of this structure, *from extravasation of the secretion into the* parenchyma of the gland and subsequent distension of its capsule The size of the cyst is modified by the character and seat of the obstruction and its relative position to the secreting gland structure The walls of the cyst are usually thin, from over distension, in cases of rapidly growing cysts, or much thickened when the growth of the tumor has been slow and accompanied by chronic proliferation and induration of the connective tissue The cyst walls in chronic cases may become cartilaginous or even ossified The inner surface is either smooth, or it presents evidences of degeneration similar to those which occur on the internal surface of arteries in the later stages of endarteritis If the canal of Wirsung is obstructed at or near its proximal end, the entire duct and its branches may become dilated, presenting the appearance of varicose veins, or a more uniformly rounded cyst may form of the size of an orange, of a child's head, or even so large as to occupy the whole abdominal cavity, as in Bozeman's case As the cyst increases in size, the gland structure disappears by absorption in consequence of *intra cystic* pressure The same cause which constitutes the obstruction will often also lead to destruction of the parenchyma of the organ, by inducing a chronic *interstitial* pancreatitis which is followed by cirrhosis or fatty degeneration of the organ Virchow[1] alludes to cysts of the pancreas under the name of ranula pancreatica, and describes two essential and distinct varieties In the first class, the entire duct is found dilated, and resembles in appearance a rosary In the second variety, the outlet of the excretory duct is obstructed, and behind the seat of obstruction the duct undergoes cystic dilatation He mentions a case that came under his observation where such a cyst had attained the size of a fist" He believes that cicatricial contractions or pressure of tumors upon the duct constitute the most frequent source of obstruction Pancreatic juice in its purity is only found in small and recent cysts Later on, in old or large cysts, various accidental products are added Albuminoid degeneration or suppuration not unfrequently take place, or hæmorrhage may occur, so that the cyst contents assume a bright red or chocolate-colored appearance Pepper found in such a cyst numerous crystals of hæmatoidin, while Hoppe found in another instance urea in the proportion of 0 12 per cent as one of the constituents of the contents of the cyst The pressure of the cyst upon neighboring organs will result in secondary pathological conditions which will interfere with the physiological performance of the functions of other organs, thus endangering the life of the patient

ÆTIOLOGY

The causes which result in the formation of small cysts of the pancreas, or cysts which result from *compression by tumors, which in themselves do not* admit of an operation for the removal and at the same time constitute a source of danger to life, do not come within the scope of this paper In the latter instance the cyst is simply a sequence of the primary cause, and as such it will seldom, if ever, become the sole or direct object of surgical treatment The causes of retention in cysts amenable to operative treatment, are such which in themselves do not imperil the life of the patient They may be classified as follows 1 *Obstruction to the outflow of the secretion from impaction of calculi in the com* mon duct or its branches 2 Partial or complete *obliteration of a portion of the duct from cicatricial* contraction 3 Sudden or gradual obstruction of the duct without diminution of its lumen from displacements of the pancreas

1 Calculi —The impaction of the pancreatic duct at its outlet may be caused by the presence of a biliary calculus in the ductus communis choledochus, at the junction of the former with the latter A case of this kind has been reported by Engel[3] In such cases *the obstruction gives rise to retention of the* secretions from the liver, and the pancreas, and dilatation of the excretory ducts in both organs Calculous concretions in the pancreatic ducts have been frequently observed to give rise to retention cysts Johnston[4] has collected 35 cases, in which, upon post-mortem examinations, stony concretions were found in the pancreas. Incrustations are not as frequent as free concretions. Gendrin has described a pancreatic cyst where the normal pancreatic secretion was converted into a fatty, chalky pap. The causes which produce a concretion in the pancreatic duct are chemical changes in the secretion itself, or, an obstruction to its free exit by inflammatory changes in or around the common duct. The degree of dilatation, other things being equal, is in direct proportion to the completeness of the obstruction to the outflow of the secretion. It may be well to allude to the possibility that in some instances a pancreatic calculus may remain stationary for an indefinite period of time in the duct, giving rise to no symptoms, and only partial obstruction, until by the action of some determining cause, it is forced into a position where it effects complete mechanical obstruction to the outflow of the fluid, and a rapid increase in the size of the cyst. As an impacted biliary calculus may give rise to pancreatic obstruction, so a pancreatic calculus, when it is impacted at a point where compression of the common bile duct can take place, will produce icterus and dilatation of the gall bladder and bile ducts. Meckel has reported such a case.[1]

[4] Calculous and other affections of the Pancreatic Ducts Am Jour Med Sciences Oct 1883

Among the specimens of pancreatic cysts so far examined, which were caused by concretions, none of them had attained the size of those which have been submitted to surgical treatment. As in most of these preparations the calculi did not completely fill the calibre of the duct, they caused only partial obstruction which would furnish an explanation of the slow growth and comparatively small size of the tumor. In the specimen described by Gould,[2] it appears that the common duct was completely closed by two calculous concretions at its entrance into the duodenum, and this cyst had attained considerable size, in fact, it is the largest cyst on record where it was proved that the dilatation was caused by the presence of a calculus. As in the successful operations on cysts of the pancreas it has been impossible to ascertain the exact nature of the obstruction, the possibility of retention from a calculus cannot be eliminated with certainty.

2. *Cicatricial Contraction.*—Cicatricial contraction is always the result of an antecedent inflammation. The cicatrix may be located in the peri-pancreatic tissue or in the substance of the gland itself. Hoppe[3] made a post mortem examination of a patient who had been deeply jaundiced during life. The gall-bladder and bile ducts were distended with bile which contained blood, the pancreatic duct was also cylindrically dilated, and many of its branches were distended into cysts the size of a hazel nut. The cause of retention of both secretions was found in a dense cicatrix which surrounded both ducts at their duodenal termination. Interstitial inflammation in the gland itself and subsequent cicatricial contraction is one of the most frequent causes of retention. Wyss has reported a case where the interstitial inflammation was limited to portions of the head of the pancreas, through which the common bile duct and the ductus Wirsungii passed, and which had resulted in dilatation of the latter and its branches, which again compressed the bile duct, producing in this manner intense icterus.[1] Bécourt has given a description of a similar specimen which he found in the Strassbourg Pathological Museum. The patient had died of icterus. The gall bladder and bile ducts were found distended, the pancreas was converted into a dense tissue which, being cut into, presented a chalky deposit four to eight inches in length and of a yellowish color. The duct of Wirsung was dilated to such an extent as to form a large cyst which occupied the whole length of the pancreas, its walls being inseparable from the substance of the gland. In this case the interstitial inflammation was more extensive and the cyst was much larger. In the cases reported by Pepper and Hjett the obstruction was due to the same cause. In Curnow's case the common duct had become obliterated at its entrance into the duodenum by catarrhal inflammation. The pancreas was atrophic, and its duct was filled with numerous calculi. The pancreatic juice had become inspissated. The cystic duct of the gall bladder was impermeable, while in the common bile duct a number of small gallstones were found.[3]

I have failed to find in the literature an allusion to stricture of the duct, the result of traumatism. The pancreas is an exceedingly slender organ of loose and somewhat friable texture, and hence, although remotely located and well protected by surrounding organs, I am of the opinion that it is more frequently the seat of injury than has been generally supposed. If the stomach is empty and the abdominal muscles relaxed, a blow over the region of the pancreas may result in serious contusion or laceration of the organ without rupture of its envelope. Again, a well directed blow over either extremity of the gland may cause a laceration of its tissues by traction force, the organ being securely fixed in its place by firm connective tissue attachments. The clinical history of several cases of rapidly growing cysts tends to prove that obstruction occurred in this manner. If the duct escapes injury, the cicatricial contraction attending and following the reparative process in the lacerated gland tissue will gradually compress the duct, or by lateral traction change its direction and thus impede the outflow of the secretion. If the duct is ruptured at the time of injury its lumen may become completely filled by a thrombus which renders it impermeable, giving rise to retention and extravasation of the secretion primarily and secondarily, to definitive occlusion of the duct by cicatricial contraction at the point of injury. I am quite convinced that in the case which I have reported the retention was the direct result of traumatic stricture of the common duct. Although this view is not supported by evidence from post-mortem examinations, it is confirmed by analogous production of cysts in other locations. It is evident that this class of cases would furnish the most favorable conditions for successful surgical treatment.

3. *Obstruction from Displacement of the Pancreas.* As the pancreas is retained in its normal transverse position by the surrounding organs and connective tissue attachments, a relative change of position of portions of the gland would result in a bending of the organ and obstruction in the duct at the point of flexion. This condition was the cause of retention in a case related by Engel,[1] who found in a woman 60 years of age that the tail of the pancreas formed a right angle upwards with the principal duct of the gland. A dislocation of this kind can occur in one of the following ways:

1. Abnormal relaxation of the connective tissue attachments of the gland permitting a portion of the organ to descend by its own weight lower in the abdominal cavity.
2. Pressure upon the gland by tumors or exudations.
3. Cicatricial contractions in the substance of the organ or peripancreatic space.

That the whole pancreas can become displaced is proven by the case reported by Dobrzycki. A man 50 years of age fell from a distance of some yards. Symptoms arising after the fall similar to those of a floating kidney. By palpation the displaced organ could be located. Saline fluid was vomited, resembling pancreatic juice. In the hypogastrium a movable tumor could be felt corresponding in position and shape to the pancreas.

DIAGNOSIS

The question of diagnosis can only be entertained in cases where the cyst has attained very considerable proportions. The most important points to be taken into consideration are the history of the case, the anatomical location of the tumor, and its relations to the surrounding organs. The cases which have been reported have occurred exclusively in adults. Sex appears to exert no determining influence. In a number of cases the clinical history alludes distinctly and forcibly to traumatism as the exciting cause. In Gussenbauer's case the beginning of the illness was traced to indiscreet eating and drinking.

In all instances of cystic tumors in the region of the pancreas, close inquiry should be made to ascertain the existence of antecedent inflammatory affections of the organ, or in its immediate vicinity. A history pointing towards the existence of a biliary or pancreatic calculi will also prove valuable in arriving at positive conclusions. Rapid growth of the tumor speaks in favor of its pancreatic origin. In Gussenbauer's, Kulenkampff's, and my own cases the tumor attained an enormous size within a few weeks. Considering the relations of these cysts to important surrounding organs, it is remarkable that they give rise to no serious symptoms aside from the pressure they exert upon adjacent organs. Pain is not a constant symptom, and when it is present it is due more to the causes which produce the cyst than the cyst itself. In this respect cysts of the pancreas form a counterpart to malignant disease when it affects this or neighboring organs. Emaciation is due either to coexisting affection of the gland, or the impairment of function of important organs by pressure of the cyst. It is never as marked in these cases as in malignant disease. The supervention of fatty stools would point towards the existence of some coexisting serious lesion of the pancreas rather than the existence of a simple cyst of the organ. This symptom was not found present, or it was overlooked, in all cases which have been operated upon. Of twenty-eight cases of stearrhœa, which were compiled by Ancelet, sixteen were examined post-mortem. In five of these there was occlusion of the ductus choledochus and pancreaticus; in three, occlusion of the pancreatic duct alone; in one, inflammation of the pancreas and some of the adjacent organs. In the remaining cases disease of the liver and the bowels or only marasmus, was found. In thirteen cases of pancreatic calculi collected by Johnston, only in three were fatty stools observed; in six cases, diarrhœa; in four cases, melaena; and constipation in the remaining six. The presence of fat in the stools is a symptom of great importance in the recognition of pancreatic disease, but that it is not of absolute diagnostic significance is proved by the well known fact that the same condition will follow upon the obstruction of the biliary passages and affections which impair the functional activity of other organs of digestion.

Obstruction of the principal duct impairs digestion more than when its distal extremity or one of the accessary ducts is involved. The actual illness of the patient is usually preceded, for a variable length of time, by more or less marked symptoms of gastro intestinal derangement, accompanied in some instances by pain in the region of the pancreas.

A peculiar color of the skin, which is believed by some to be characteristic of pancreatic disease, must be mentioned, as it was observed in several cases of calculous affection and cysts of the pancreas. The appearance presented by these patients is variably described as being unhealthy, pale-yellow, dirty, or earthy. The intimate relations of the cyst to the cœliac plexus will explain the cause of cœliac neuralgia which is met with in some of these cases. Atrophy of the cœliac plexus, from long continued pressure, may give rise to mellituria for the same reason that Klebs has affirmed, that partial extirpation or atrophy of the cœliac plexus will cause the presence of sugar in the urine. Diverse diseases of the pancreas have also been known to produce diabetes mellitus. Cases of this kind have been reported by Cowley (1788), Bright, Elliotson, Frerichs, Fles, Hartsen, Silver, Recklinghausen, Munk, Seegen, and Friedreich. Klebs demonstrated by his experiments that complete extirpation of the pancreas or ligature of its duct invariably gave negative results, as far as diabetes was concerned, and this may account for the fact that no sugar was found in the urine of the cases reported in this paper. The cyst, when exam med early, before it has attained considerable size, is always found in the region normally occupied by the pancreas The exact location, however, is not always uniform, as it will depend upon the portion of the pancreas from which the cyst has taken its primary origin It may be situated below the right lobe of the liver, as in Kulenkampff's case, in the epigastric region, as in Gussenbauer's case, or in the left hypochondrium, as noted in my case When the tumor has attained a large size, or occupies the whole abdominal cavity, it will be difficult, and in the latter instance impossible, to determine by any known means its primary origin In such cases it is of paramount importance to study its relations to adjacent organs The tumor is always and invariably situated in the bursa omentalis, and from this point, as it increases in size, it encroaches upon the space occupied by adjacent organs The stomach is pushed forward in all cases, and later to the right The transverse colon is displaced downwards, the spleen to the left, and the diaphragm and contents of the chest upwards The cyst being in direct contact with the diaphragm, it usually ascends and descends with the respiratory movements of the chest

[2] Fall von beweglicher Bauchspeicheldruse. Virchow u. Hirsch's Jahresb. 1878, vol. ii, p. 215.

[1] Etudes sur les maladies du pancréas. Paris, 1867.

[2] Op. cit.

In doubtful cases it will become necessary to inflate the stomach and colon, with a view to ascertain their relative position to the cyst If the patient is a female, and the tumor occupies the entire abdominal cavity, it will simulate cystic disease of the ovary so closely that a differential diagnosis between the two is impossible The cases reported by Luecke, Bozeman, and Rokitansky furnish adequate proof of the correctness of this statement The proximity of the abdominal aorta is such that the impulse of the artery is imparted to the tumor, which, however, pulsates only in one direction—away from the artery—a fact which will always distinguish it from an aneurism Unless the cyst is exceedingly tense a sense of fluctuation is always imparted by palpation Palpation is rendered difficult on account of the deep location of the pancreas and the rigidity of the recti abdominis muscles The normal pancreas can only be felt under certain favorable conditions Concerning this point Sir William Jenner says "By deeply depressing the abdominal walls about a hand's breadth below the umbilicus, by then rolling the subjacent parts under the hand (the stomach and colon must be empty), it might be possible to detect it in an individual who is thin, and whose tissues are lax" In case the examination is rendered difficult on account of great rigidity of the abdominal muscles, this obstacle can be overcome by examining the patient while under the influence of an anæsthetic An exploratory puncture with a fine and perfectly aseptic needle of a hypodermic syringe will not only add material diagnostic information by revealing the character of the cyst contents, but the procedure will also settle the question as to the existence or absence of adhesions between the cyst walls and the parietal peritoneum In the differential diagnosis the following affections will come up for consideration 1 Malignant disease of the pancreas or adjacent organs 2 Aneurism 3 Echinococcus of liver, spleen, or peritoneum 4 Affections of retroperitoneal lymphatic glands 5 Hydro or pyo nephrosis 6 Cystic disease of supra renal capsule 7 Circumscribed peritonitis with exudation 8 Ascites 9 Cystic disease of ovary

1 *Malignant Disease of the Pancreas or Adjacent Organs*—Carcinoma, or sarcoma of the pancreas or adjacent organs, as in every other locality, always manifest their presence by their most characteristic clinical features—pain, emaciation, and progressive local and general infection The age of the patient and the previous history of the case will also furnish important diagnostic information Large pancreatic cysts are unilocular, while, on the other hand, if a malignant tumor has undergone cystic degeneration, usually more than one cyst can be recognized Hardness and irregularity of surface speak in favor of malignancy, on the other hand, smoothness and a regular round or oval contour of the tumor are constant features of a pancreatic cyst The time which has elapsed since the beginning of the illness is also of importance A rapidly growing pancreatic cyst will assume a size in two or three weeks which even for a malignant tumor would require as many months

2 *Aneurism*—An aneurism of the abdominal aorta can be distinguished from a pulsating pancreatic cyst by its pulsations being felt in all directions, and by the presence of a bruit As a further test, the suggestion of Dr Pepper may be resorted to, which consists in placing the patient in the genu pectoral position, when the tumor, by gravitation, will leave the aorta and all pulsation will cease Steady pressure will diminish the volume of an aneurism, but will have no effect on a cyst of the pancreas

3 *Echinococcus Cysts*—Echinococcus cysts of the liver, spleen, or peritoneum could be easily mistaken for a cyst of the pancreas The peculiar fremitus sometimes felt on palpating an echinococcus cyst should always be sought for Multiplicity of cysts would decide in favor of something else than a pancreatic cyst The presence of hooklets in the aspirated fluid would furnish positive evidence in favor of the presence of an echinococcus cyst, while their absence would not exclude the possibility of the tumor being a sterile echinococcus cyst As the surgical treatment in both instances would be identical, it is sufficient for practical purposes to narrow the diagnosis down to a probable existence of either affection

4 *Affections of retroperitoneal lymphatic glands*—Neoplasms, inflammation, suppuration, or hypertrophy of the retroperitoneal glands behind the pancreas might simulate a pancreatic cyst, and as a wrong diagnosis in such an event might prove disastrous to the patient, and reflect discredit upon the surgeon, every diagnostic resource should be exhausted in order to prevent such error Enlargement of the lymphatic glands, from any cause, sufficient in extent to simulate a pancreatic cyst, would almost of necessity give rise to serious constitutional disturbances and extension of the disease to neighboring organs

5 *Hydro- or Pyo nephrosis*—In hydro- or pyonephrosis, the early clinical history will present a group of symptoms pointing toward some lesion in

the pelvis of the kidney, or ureter. A chemical and microscopical examination of the urine may furnish conclusive evidence of the existence of some renal affection which has produced the obstruction. Tumors of the kidney usually occupy a lower place and are more laterally located than tumors originating in the pancreas. In case of a pancreatic cyst, the lumbar region below the kidney is tympanitic, which is not the case in hydro- or pyo nephrosis. In case of doubt an exploratory puncture may enable us to arrive at a positive conclusion.

6. *Cystic disease of the suprarenal capsule.*—The suprarenal capsule may be the seat of cystic degeneration, and simulate a cyst of the pancreas so closely that a differential diagnosis is impossible. In Gussenbauer's case, the diagnosis remained doubtful between a cyst of the pancreas and a cyst of the suprarenal capsule. The bronzed skin so frequently observed in diseases of the suprarenal capsule has been also seen in affections of the pancreas. As the operative treatment in either case would be the same, it is not essential for practical purposes to make a positive diagnostic distinction between the two.

7. *Circumscribed peritonitis with exudation.*—Primary peritonitis, with a circumscribed exudation in the region of the pancreas, would reveal a history pointing toward an inflammatory affection accompanied by the usual symptoms attending inflammation of this membrane. Fever, pain, and tenderness are symptoms which are either foreign to the history of cysts of the pancreas, or, when present, they are less intense than in peritoneal inflammations. In peritonitis, the exudation would be necessarily in the peritoneal cavity, while pancreatic cysts always occupy the omental bursa.

8. *Ascites.*—The question of diagnosis between a cyst of the pancreas and ascites can only arise in case the whole abdominal cavity is distended by the tumor or effusion. The causes which produce ascites must be considered separately and individually, as they are usually of such a character as to exclude a suspicion of pancreatic disease, a satisfactory diagnosis can be reached without an exploratory puncture; but, if any doubt remains, this harmless procedure will furnish the requisite information.

9. *Cystic disease of ovary.*—From the cases reported we have gleaned that, in at least three cases, large cysts of the pancreas were mistaken for cystic disease of the ovary by surgeons of prominence and ability who made thorough and repeated examinations. It is not difficult to conceive that in case the tumor has assumed such dimensions as to fill the entire abdominal cavity, it would be impossible to differentiate between a cyst of the pancreas and the ovary, even by a most scrutinizing examination. The physical signs presented by either resemble each other so closely that they cannot be relied upon in discriminating one from the other. The early history of the case, if it can be obtained from a reliable source, is of more diagnostic value. In pancreatic cysts, the early symptoms are usually referred to disturbance of the digestive functions, and the patient has been aware of the presence of a tumor in the upper portion of the abdominal cavity. An ovarian tumor necessarily begins in the opposite portion of the abdominal cavity, and gives rise to pelvic distress and disturbances of the menstrual function. As the surgical treatment in both instances would be the same, it is practically not essential to make a positive distinction between the two before an exploratory incision will reveal the true nature and origin of the cyst. In recapitulation it may be stated that a positive diagnosis has so far not been made in a single instance, and that for all practical purposes it is only essential to make a probable diagnosis between a pancreatic cyst, or some other kind of a cyst, which would call for the same kind of surgical treatment. In very obscure cases, an exploratory incision, under antiseptic precautions, for diagnostic purposes, is a justifiable procedure.

PROGNOSIS

Physiologists are agreed in assigning to the pancreas a most important function in the digestion of organic food. We know that by a special ferment it assists in the transformation of starch into dextrine and sugar, and in the digestion of albumens and fat. We should naturally expect that in diseases of this organ the digestion of these substances would be impaired in proportion to the amount of gland tissue destroyed. *On the other hand, we have abundant* evidence to show that even total disorganization or destruction of the pancreas is not incompatible with normal digestion and perfect health. It would seem to appear that in the absence of the pancreatic secretion other organs assume a vicarious action, and digestion proceeds unimpaired. It is also important to remember that even a large cyst of the pancreas does not necessarily result in extensive destruction of the gland, and that the remaining gland tissue continues to secrete and discharge a sufficient amount of pancreatic juice. In Bozeman's case, the cyst occupied the entire abdominal cavity, and yet, at the operation, the greater portion of the gland was found healthy in structure. The integrity of the structure and function of the gland depends less on the pressure of the cyst than the causes which were concerned in its production. *The dangers arising from the cyst* itself consist in: 1. Its interference with the functions of other abdominal organs by pressure. 2. Rupture of cyst and escape of its contents into adjacent hollow organs or peritoneal cavity. Compression of the stomach and interference with its normal peristaltic action is a constant occurrence when the cyst has developed to any considerable size. When such is the case, vomiting soon after meals takes place, as was noted in a number of cases which have been reported. When the cyst is of very large size most all of the abdominal organs suffer by compression, and both digestion and absorption are impaired by mechanical pressure. The diaphragm being at the same time pushed upwards, the heart and lungs are displaced in the same direction, and embarrassment of circulation and respiration follows as a necessary sequence. Like any other benign abdominal tumor, the cyst proves dangerous to life by interfering mechanically with the functions of more essential and important organs. The second source of danger is rupture of the cyst and escape of its contents into adjacent organs, an accident which may be followed by immediate death from hæmorrhage, or the life of the patient is placed in jeopardy by suppurative inflammation in the interior of the cyst, or peritonitis in case the contents have escaped into the peritoneal cavity. In Pepper's case, the immediate cause of death was hæmorrhage consequent upon rupture of the cyst into the stomach.[1] At the post-mortem examination a large quantity of blood was found in the stomach and intestine, which had entered through an opening about one half inch in diameter, close to the proximal termination of the ductus communis. A probe passed through this opening directly entered a cyst in the head of the pancreas. A communication with any portion of the gastro-intestinal tract would almost of necessity lead to infection and suppurative inflammation in the interior of the cyst, which, under unfavorable circumstances, might lead to a fatal termination from septicæmia or extension of inflammation to adjacent organs. The prognosis may be said to depend: 1. On the nature and cause of obstruction. 2. Size of cyst. 3. The absence or presence of complications.

TREATMENT.

In the treatment of a pancreatic cyst, the indications are the same as in the treatment of any other kind of cysts, viz.: 1. Extirpation of the cyst. 2. Evacuation of its contents and obliteration of the cyst.

Extirpation was attempted in Bozeman's and Rokitansky's cases, in the former instance with complete success, in the latter the operation was not completed, and the patient died a few days afterwards, of septic peritonitis. It is proper to state that in both cases the operation was done for the removal of a supposed ovarian cyst and that a correct diagnosis was made in the first case during the operation, after the pedicle was traced to the pancreas and the intact portions of the gland were identified. In the second case the post-mortem examination revealed the true nature and location of the cyst. The brilliant result obtained by Dr. Bozeman is well calculated to stimulate others to follow his example. Extirpation of the cyst would guard most effectually against the formation of a permanent pancreatic fistula, but, on account of the deep location of the pancreas, shortness or absence of a pedicle, and the many obstacles thrown in the way of the operator by adjacent organs, the procedure becomes one surrounded by innumerable difficulties, and in the present state of our science, of doubtful propriety. Simple evacuation of the cyst contents by means of the aspirator, offers two principal objections against its adoption in the treatment of cysts of the pancreas: 1. Escape of cyst contents into the peritoneal cavity. 2. Re-accumulation of secretion.

Reasoning from analogy, we should naturally expect that when pancreatic juice is brought in contact with the peritoneum, it would produce a destructive effect upon it by its digestive properties, or, it might be even followed by diffuse peritonitis. In opposition to this assumption it is affirmed that in experiments on the pancreas it happens quite frequently, that pancreatic juice escapes into the abdominal cavity from the canula introduced into the pancreatic duct, without any bad results on the animals. Concerning this point Heidenhain[1] says: "The animals do not suffer from this circumstance as the duct is regenerated in spite of the wounded surface being bathed in the secretion. Nevertheless it is difficult to explain this. Why do not the wounded and suppurating tissues undergo digestion by the pancreatic juice? The efficacy of the albumin ferment is destroyed in some way I presume, probably by being changed into zymogen, the living tissues having the same effect on the juice as Podolinski observed by treating the pancreatic juice with pulverized zinc or yeast ferment." Although small quantities of pancreatic juice may escape into the peritoneal cavity of an animal without any serious consequences, we have no evidence to show that the peritoneal cavity in man is possessed of the same immunity against such accident, and it would not be prudent to expose a patient to such risk until more light is thrown on this subject by further observation and experiment. At the same time we must not forget that pure pancreatic juice is only found in small cysts, as the contents of large cysts have undergone various transformations, and are mixed with different accidental products, which might prove an additional source of danger in producing peritonitis. In all of the cysts where a pancreatic fistula was established, the artificial opening continued to discharge the secretion for a variable period of time, and in two cases the discharge had not ceased at the time the report was made, and hence re-accumulation would have been inevitable, in case the fluid had been removed by aspiration. For these reasons, the treatment by aspiration should be limited to cysts of moderate size, and where adhesions have formed between the cyst and the anterior walls of the abdomen. In cases presenting these favorable conditions, aspiration deserves a trial, and may be repeated as often as required, or until symptoms arise, which call for more radical measures. The needle should always be thoroughly disinfected by passing it through the flame of a spirit lamp, and by dipping it in a five per cent. solution of carbolic acid. The puncture is made obliquely, so as to prevent the formation of a fistulous opening. The fluid should be withdrawn slowly and the cyst emptied as completely as possible.

After the operation gentle pressure should be made over the cyst, by applying a compress and elastic bandage. The safest, and at the same time the most efficient treatment, consists in establishing a pancreatic fistula. The operation which accomplishes this purpose most safely and in the shortest time, consists in exposing the cyst by an incision, stitching its walls to the margins of the wound. The same aseptic precautions must be observed before, during, and after the operation, as in any other abdominal operation. The stomach being generally pushed forward, upward, and toward the right by the cyst, it is advisable to empty this organ completely as a preliminary measure by abstinence of food, and the use of the syphon irrigator Except in my case the incision was always made in the linea alba It seems to me that the incision should always be made over the most prominent part of the tumor, and as near as possible over the seat of obstruction In following this rule, we select the place where we are most apt to find adhesions, at the same time we establish the straightest and most direct route to the primary origin of the cyst An incision through the linea alba, or parallel with the costal arch, will afford the easiest access with a minimum risk of injury to important parts The external incision should be at least four inches in length, while the peritoneum should only be opened to the extent of two inches for the purpose of making an exploratory examination, to be enlarged as occasion may require If adhesions are found between the cyst and the omentum, and the omentum and the parietal peritoneum, the cyst is punctured with an exploratory needle, and, if the diagnosis is corroborated, the operation is finished by incising and draining the cyst If no adhesions are found between the omentum and peritoneum, the former is incised so as to expose the cyst wall, when either of the following plans may be pursued The parietal peritoneum is stitched to the skin with catgut The margins of the omental wound are pushed back under the abdominal walls so as to expose the cyst freely, when the wound is packed from the bottom with iodoform gauze, and an antiseptic dressing is applied and retained for six or eight days, or until adhesions have formed between the cyst and the margins of the wound which have effectually shut off the peritoneal cavity, when the cyst is incised and drained

---

[1] Amer. Journ. Med. Sciences, 1871, p. 159.

[1] Archiv f. d. gesammte Physiologie, vol. xii, p. 466.

Suturing of the cyst wall to the margins of the wound as a preliminary operation should never be resorted to, as on account of thinness of the cyst walls there is danger of escape of fluid into the peritoneal cavity from the punctures made by the needle, an occurrence which the procedure was intended to obviate With proper care, however, the operation can be completed at once The cyst wall is grasped with two many toothed forceps, and drawn forward so as to bring it in accurate and close contact with the margins of the wound, when the fluid is removed with an aspirator or trocar with the same care as in emptying an ovarian cyst As the cyst becomes empty it is pulled through the wound, which obviates any further danger of escape of fluid into the peritoneal cavity When the cyst is nearly empty it is freely incised and sutured to the peritoneal lining of the abdominal wound The drainage tube should be fully three-quarters of an inch in diameter, and must reach from the bottom of the cyst to the surface of the wound After emptying the cyst completely by compression, and placing the patient on his side, a large Lister dressing is applied for the purpose of guarding against infection, and to absorb the secretions Frequent change of dressing may be required on account of copious escape of pancreatic secretion Past experience would dictate the advisability of protecting the skin against the digestive action of the pancreatic juice by applying freely carbolated oil The antiseptic dressings should not be abandoned until the peritoneal cavity has become completely closed by firm adhesions, and the size of the cyst has been reduced to a fistulous tract The drainage tube is shortened from time to time, as the depth of the fistulous opening is diminished by obliteration of the cyst from the bottom of the tract The speedy obliteration of the cyst will depend on the continuance, abatement, or removal of the obstructing cause, or the condition of the gland tissue distal to the seat of obstruction If the stricture in the common duct of the pancreas is complete and of a permanent character, the obstruction will continue, and, if healthy gland tissue remains on the distal side, the fistula will continue to discharge pancreatic juice If the inflammation which caused the obliteration of the duct subsides, and the passage again becomes permeable, the natural outlet will be again established and the artificial duct will become obliterated If an impacted calculus has caused the retention, and the fistula continues to discharge, a careful examination should be made to detect the calculus, and, if found, an effort should be made to remove it through the fistulous opening If the obstruction has become permanent and the gland tissue on the distal side has become destroyed, either by the cause or causes which produced the obstruction, or by the intra cystic pressure, that portion of the organ has been deprived of its functional capacity, and, as no pancreatic juice is secreted, definitive obliteration of the cyst and permanent closure of the fistulous tract will take place in a comparatively short time

In recapitulation, I believe I am justified in submitting for your further consideration and discussion the following conclusions

1 Cysts of the pancreas are true retention cysts

2 Cicatricial contraction or obliteration of the common duct or its branches, and impacted calculi, are the most frequent causes of cysts of the pancreas

3 A positive diagnosis of a cyst of the pancreas is impossible, a probable diagnosis between it and some other kind of cysts amenable to the same surgical treatment, is adequate for all practical purposes

4 The formation of a pancreatic fistula under antiseptic precautions recommends itself as the safest and most expedient operation in the treatment of Cysts of the Pancreas

(To be concluded)

A SUGGESTION ON THE PROPER ALTERNATION OF REST WITH EFFORT, AS ESSENTIAL TO HEALTH AND STRENGTH[1]

BY JACOB I WILLIAMS, M D,
OF BOSTON MASS

In the early part of my professional pupilage, I heard a suggestion from the venerable Dr John C Warren, long since deceased, to this effect He said "When engaged in a long surgical operation of half an hour or more in duration, the eyes will sometimes become fatigued, and it will be difficult and unsafe to continue the operation with them in that condition

---

[1] Read in the Section of Dental and Oral Surgery at the Thirty Sixth Annual Meeting of the American Medical Association

It is better, under such circumstances, to raise the eyes and let them rest upon some object in a distant part of the room, or, if you can leave the operation, step to the window and look out for a minute or two; you will then return with the eyes refreshed, and can see as well as ever." And more recently, one of the most eminent of American oculists has written, that "one great cause of injury to vision is the *continuous* application of the eyes to book or work *after* they have become fatigued." This mention is made because the ideas therein contained represent a principle which holds good in the use of any faculty.

There is a very common belief that mere "exercise strengthens," without the recognition of any other element as necessary to that end. And so some seem to think that the more and longer they can possibly exert their faculties, the stronger they must be. As a result, we see fatigue carried to exhaustion, which is another name for weakening or debility.

Instances are common in various occupations and ages of individuals. The youth is too often crowded with study continuously through the day and perhaps a part of the night, till the mental process becomes actually debilitated, sometimes permanently. The business or professional man will not, or cannot pause for rest till he finds that he positively must, and sometimes not then, but drops at his post. The ambitious rower or pedestrian continues his exercise till his strength is absolutely gone, and sometimes his constitution shattered.

In our special department, the practitioner will labor too many hours continuously during the day, and perhaps the evening, till his nerves shake like so much loose cordage in the winds. And if he does not, as to my knowledge has occurred in one instance at least, fall dead by the chair, he finds a very long vacation needed to bring back a semblance of his former tone.

We also cannot ignore the fact that patients are too often allowed to suffer a continuance of endurance which has required days to recover from, and has sometimes been followed by more serious results. I emphasize the term *continuous* effort, because from that comes the harm when carried beyond the point of simple fatigue, on to the condition of exhaustion; that point of course, varying in different persons, and in the same person at different times.

This rule, then, should be learned, and the earlier the better, namely: to rest, if possible, just when we are tired, and to let our patients do the same.

SOME ERRORS IN PHYSICAL DIAGNOSIS.[1]

BY WM. PORTER, M.D.,

OF ST. LOUIS.

In this Association clinical facts are most in demand, and you are physicians in active practice with probably little time or inclination for the discussion of theories. I have, therefore, thought best that I should narrate briefly the history of a few cases in which errors have been made by myself and others in the early diagnosis. These have been selected not because of their rarity or because gross carelessness was exhibited in the examination, but rather because in each unusual conditions existed. In each was a hidden snag in the channel of investigation. May the record of them, and whatever of discussion may follow, make plainer sailing for all of us.

The first case is one in which the diagnosis at the initial examination was hæmoptysis. Mr. M., at 27, of slight figure but in fairly good general health, consulted me two years ago, after having had slight hæmorrhage, in which the blood came freely, though not in large quantities, mixed with mucus. At the time, he had a mild attack of acute bronchitis, and was somewhat hoarse. He referred to a well defined pain in the lower right clavicular region, and was impressed with the idea that there was the origin of the hæmorrhage. The bleeding had quite ceased before I saw him. Upon physical examination I found slight pharyngitis, some redness of the vocal cords, and laryngeal hyperæmia, and in the right infra clavicular region, at the place where he had the pain, there was some dulness and small mucous râles. There was mucous non-purulent expectoration, slight elevation of temperature, and pulse of 98. I felt, with this evidence, justified in giving a somewhat guarded opinion, though not based on his own conclusions. A few weeks after I saw him during a hæmorrhage, and he again referred to the pain in the chest. This time I found little or no dulness, and no râles or other symptoms of bronchial or pulmonary lesion. Looking into his pharynx I saw blood slowly trickling down from behind the soft palate, and with the rhinoscopic mirror found the lesion to be a ruptured superficial vessel high up on the posterior pharyngeal wall. A net work of these vessels, some of them much distended—a phlebecstasis pharyngea—explained the origin of the recurring hæmorrhage. At the first examination the local symptoms as well as the somewhat abnormal pulse and temperature were due to the bronchitis, from which he was convalescing, combined, as it may have been, with some localized lobular inflammation.

Hæmorrhage from the larynx and pharynx may, under certain conditions, be thought to be hæmoptysis, especially if there be present some abnormal bronchial or pulmonary condition. Laryngeal hæmorrhages are now well recognized phenomena, though not very often seen even by the laryngologist. Sometimes the lesion is sub mucous, as reported by Fraenkel[1] and Sommerbrodt,[2] when rapid infiltration of the laryngeal tissues results, and consequent dyspnœa. This class is not so likely to be mistaken for pulmonary hæmorrhage as where the laryngeal lesion is capillary. Here there may be a more or less profuse bleeding without pronounced subjective laryngeal symptoms. Hartman[3] reports such a case in which had there been no laryngoscopic examination, the hæmorrhage would undoubtedly have been thought to be of bronchial origin. Hæmorrhages from the pharynx may also, as in the example given, be relegated to pulmonary origin. There are few cases of bleeding from the air passages in which a pharyngeal and laryngeal examination should be omitted, if only to confirm a diagnosis by exclusion.

[2] Berlin Klin. Wochenschrift, 1878.
[3] American Laryngological Association, 1879.

The next case is one in which, while there was no doubt of the location of the disease, the error was as to the nature of it. I quote from my case book of 1876. Mr. T., æt. 50, came under notice in September of that year, with the physical signs of phthisis sufficiently well marked to warrant a diagnosis. There was a dulness over a small area two and one-half inches below the left clavicle prolonged expiration, cough, expectoration and shortness of breath. The patient was losing flesh rapidly, and was very weak. At first I did not suspect what now seems to have been the true nature of the disease, and he was treated as an ordinary case of phthisis. He returned to his home in the country, but grew worse, until October, when I saw him again. He then complained of pain over the tibia, and had frequent headaches. Upon inquiry he gave a history of syphilis contracted twelve years before but thought he had been entirely cured. Under specific treatment he was relieved of his pain, and his pulmonary symptoms became less urgent. Thinking from this that syphilis had something to do with the disease in the lung, I gave him large doses of iodide of potassium and inunctions of mercurial ointment. His cough and expectoration soon almost disappeared, and after a careful examination the following year I failed to find any evidence of deposit in the lung. During the last three months he had no treatment but the specific medication mentioned. He had improved in weight, strength, and appetite, and considered himself almost well. Though it is well not to be too confident, yet there is strong circumstantial evidence to support the theory that this patient was suffering from tertiary syphilis, that there was a deposit or syphilitic nodule in the left lung, where at first it was thought there was tubercular infiltration, and that this, under the influence of anti syphilitic remedies, was removed, at least so far as to give no evidence of its existence.

In every case the diagnosis must depend in a great measure upon the history of the disease. There can be but little difference between the physical signs of this and that of ordinary tubercular disease. In both forms there is a deposit, there may be hæmorrhage, and cavities may result from the breaking down of the infiltrated masses. It may be safe to suspect syphilitic phthisis when the physical symptoms point to slowly progressing disease in the middle and lower parts of the lung, the apices being free, in cases where there is a decided history of syphilis. The suspicion may be confirmed if, when specific treatment is adopted, improvement takes place. It is well to remember in investigating thoracic disease, that syphilis of the lung is now a recognized condition, and may closely simulate phthisis pulmonalis in the physical symptoms. While so able a writer as Hutchinson, in his essay on "Constitutional Syphilis," enumerates almost every organ of the body except the lungs as liable to invasion from tertiary disease, on the other hand pulmonary syphilis is described by Fornier, Goodhart, Von Barensprung, and Rollet, in Europe, and reports were made in this country in 1877 by Tiffanny[1] and by the writer. More recently additional evidence has been secured.

During the past year a young lady was sent to me on account of great obstruction to deglutition. There seemed to be almost a complete stricture of the œsophagus. There was a history of dysphagia, and well defined pain beneath the sternum and above the cardiac orifice for eighteen months. For eight months the patient had subsisted on liquid food alone. An attempt to pass an œsophageal sound failed. There had been no attack previous. Organic stricture was thought probable, spasmodic stricture possible. The patient was of exceedingly nervous temperament, and much reduced in strength and weight. After some time devoted to general tonic treatment, the bougie No. 12, which at the first gave much pain, was again used. This time it passed through the supposed stricture easily. That afternoon the patient had less difficulty in deglutition, and has continued to improve. I have not used the bougie since the first successful attempt at passing it two months ago, and yet she is now eating without difficulty, still in some dread of choking. In this instance the diagnosis of spasmodic stricture is assured, rather than of organic disease. The main feature here is the quick relief afforded by a single passage of the instrument. How much local and how much mental effect was produced by the procedure I know not. I only know the very troublesome condition is removed, to the great relief both of the patient and myself.

A case parallel to this is recorded by Dr. Henna, where, in a most obstinate case, the sound was passed but once, and almost immediate relief resulted. For nearly five months, *i. e.*, to date of publication, there was not the slightest return of the difficulty.

In the following case—a unique one in some respects—there was an error in the diagnosis, and an even more surprising result from slight instrumental interference. I quote again from my case book. Isaac H., a carpenter, æt. 30, came to me with this history. His general health had always been good, and he had had no trouble with his voice until the winter of 1862. At that time he was in the army, and much exposed. One day, after it had been more than usually wet and cold, to use his own words, "he caught cold in the throat." Hoarseness followed, and in twenty four hours his voice was quite gone. His throat felt sore and stiff at the time and he had some difficulty in swallowing, both these symptoms soon passed away. Since then, eleven and one half years, he had never spoken aloud. Several physicians had examined him, and had decided that there was some important organic lesion—the exact diagnosis I know not—and that the aphonia was permanent. Patient was a strong, well developed man, without any symptoms of nervousness or debility, such as are often found in cases of so called "hysterical aphonia." Upon a laryngoscopic examination, I found a slight bilateral paralysis of the adductor muscles of the vocal cords, which was barely sufficient to produce aphonia, the cords moving when phonation was attempted almost to the median line, leaving only a narrow space between them. The mucous membrane was of natural color, and there was no thickening or signs of recent inflammation. The case seemed in every way a proper one for faradization. This was done by means of Stoehrer's induction apparatus and Mackenzie's electrode, and in this way an electric current was easily applied to the affected muscles. The first day the patient was able to make a distinct vocal sound, and after the second application the following day, phonation was completely restored. Since then, his voice has remained perfect. It is needless to say that the physician was as much surprised as the patient at the unlooked for result.

---

[1] Am. Jour. Med. Sciences, July, 1877.
Missouri State Med. Association, 1877.
[3] Hospital Gazette, 1879.

From the history of this case, I have no doubt that the aphonia was produced in the first instance by catarrhal congestion, which affected the nervous supply of the adductor muscles of the cords, and after the congestion had disappeared, the nerve force was not sufficiently evolved to produce complete approximation. It is interesting to note that although there had been no complete action of the parts for so long, there was no apparent atrophy of either the cords or muscles, and that such slight treatment was enough to relieve aphonia so persistent. Mackenzie, in commenting upon this case, says that probably for a long time the patient had the power of vocalization, but that for some reason that power was not evolved. I cannot think that so little treatment could so quickly affect an organic change of so long duration. This man is now living in Western Pennsylvania, and has had no trouble with his voice since its recovery, now more than ten years ago.

Let me give the outline of two cases in which the error in diagnosis was in the location of the cause of disease. The first is one of that now well recognized class—reflex asthma. Mrs. P., of Tennessee, æt. 51, of good family history, and in former good health, had severe and frequent paroxysms of asthma during two years. She was, when I saw her, much reduced, scarcely able to walk, and exhibited all the physical signs usual in such cases. At first all efforts were directed to reach the disease *in situ*, without effect. Noticing that there was some nasal obstruction, I easily discovered the nares filled by small polypi. These being removed, the dyspnœa gradually disappeared. Since then I have seen a number of cases of asthma from reflex causes, and many more have been reported by others, but I need hardly say that this first case carried its lesson to me.

The last case is one which greatly puzzled me at the time, and was finally solved by the patient himself. Mr. J. consulted me on account of chronic naso-pharyngeal catarrh. So great was the disturbance that it seriously interfered with his duties of managing editor of a daily paper. There was profuse discharge of muco-purulent matter, both by the nostril and pharynx, with thickening and some ulceration of the mucous membrane lining the cavities. After patient treatment for some time there was an improvement in some of the symptoms and in the appearance of the cavities, but the offensive discharge, though lessened, still continued, especially from the right nostril. Finally, the patient became discouraged and abandoned treatment. Some months after, he came to see me with the statement that he was well. He showed me a small hard substance which had been expelled from the right nostril, followed by a rapid change in the quality and quantity of the discharge, which in a short time ceased. The foreign body was an embryotic tooth which had evidently ulcerated through into the maxillary sinus and so escaped into the nostril. It will be remembered that the floor of the antrum is often very thin, and conical processes corresponding to the first and second molar teeth are found; in fact, sometimes the floor is perforated by the teeth. Salter[1] says the antrum may extend so as to be in relation to all of the teeth of the true maxilla from the canine to the *dens sapientiæ*.

This is one of the few cases in which I can place a mistake to the credit of myself and the advantage of my patient, for had the cause of the persistent trouble been known, I would at least have suggested an operation. It was better as it was. In reviewing these mistakes, I trust I have not in so doing added to the list. The most proficient among us often err. We are fortunate when we can learn from our errors.

MEDICAL PROGRESS

ANATOMY AND PHYSIOLOGY

The Effect of General Anæsthesia on Cocaine Mydriasis.—Mr. Simeon Snell, in a note on this subject, says: "I am not aware that any observations have as yet been recorded as to effects of the general anæsthetics on cocaine mydriasis. So much has, however, been written respecting this remarkable and most valuable drug, that it is hardly safe to state now that any observation is original. At all events, I desire to draw attention to the following.

"A short time since, cocaine was inserted into the eye of a case of strabismus, on which it was intended to operate, but for which it was afterwards deemed desirable to administer ether to overcome the nervousness of the patient. The phenomena about to be mentioned were then noticed. The cocaine had caused wide dilation of the pupil, but during the administration of the ether, and whilst under the anæsthetic, the mydriasis was observed to pass off and the pupil to become just as small as the other. The observation has been repeated in other instances. A few days since, in a case of nævus of the orbit in a baby, about to be treated with electrolysis, the pupil of one eye was purposely dilated with cocaine (five per cent. solution of hydrochlorate). Chloroform was then administered, and whilst the child was getting under its influence, the pupil became less large, and, when fully narcosed, it was as small as the pupil of the other eye. On the day this is written, the observation was repeated in a case for which ether was administered, and, after recovery from the effects of the anæsthetic (ether), the pupil was observed to have become dilated again

---

[1] Abscess of the Antrum. Holmes's System of Surgery.

It clearly follows, from these observations, that we have in cocaine a mydriatic that acts in a different manner from atropine and other agents of the same class It is well known that atropine mydriasis remains unaffected when ether or chloroform is administered, a result in accordance with the opinion that the drug acts by paralysing the sphincter iridis, and affecting the muscles, or rather the peripheral endings of the nerves which supply them The observations I have recorded would appear to support the theory advanced by Mr Walter H Jessop He maintains that cocaine acts as an irritant to the endings of the cervical sympathetic or mydriatic nerve of the eye At all events, it is seen that, when, on the administration of a general anæsthetic (ether or chloroform), the muscular system has become relaxed, and narcosis has occurred, the cocainised eye recovers itself These observations appear to be of interest, both apart from, and in connection with, Mr Jessop's interesting investigations I am inclined to think that chloroform more fully overcomes the mydriasis than ether —*British Medical Journal, July 25, 1885*

ACTION OF CHINOLINE TARTRATE —At the close of an article on this subject, DR CONRAD BEHRENS draws the following conclusions

1 Chinoline tartrate is a powerful agent, producing death by asphyxia

2 The drug increases the force and frequency of the respirations by stimulating the vagus roots in the lung

3 It paralysis respiration finally by a secondary depressant action upon the respiratory centre

4 It does not cause convulsions

5 It lessens and finally abolishes reflex action by a direct action upon the cord, and by a slight action upon the muscles and nerves

6 It diminishes or abolishes muscular contractility respectively when applied through the circulation or directly

7 It coagulates myosin and albumen

8 It causes insalivation by paralysis of the secretory fibres of the chorda tympani, increases the flow of bile, has no action upon the spleen

9 It lowers blood-pressure by paralyzing the vaso-motor centres and by a direct depressant action upon the heart-muscle

10 It diminishes the pulse-rate by direct action upon the heart

11 It lowers the temperature by increasing the loss of heat

12 It is a powerful antiseptic, and, finally

13 Its paths of elimination are not known —*Therapeutic Gazette*, July, 1885

MATERIA MEDICA AND THERAPEUTICS

THE EXTERNAL EMPLOYMENT OF CRYSOPHANIC ACID —Under the name of traumaticine, a solution of gutta-percha has been employed for some time as an excipient in certain drugs, as the solution painted on the skin by the aid of a brush leaves firm pellicles which will serve to preserve the skin from friction DR AUSPITZ has recently employed this solution for the external application of crysophanic acid, so as to cause it to adhere to the skin and protect it from rubbing, and to prevent this drug from staining bodies which come in contact with it This preparation has been employed with success in the treatment of psoriasis, and it is evident that it may serve for the application of a large number of drugs which are soluble or capable of suspension in chloroform, and which appear to the physician a valuable method of treatment Auspitz (*Nouveaux Remedes*, May 15, 1885) dissolves one part of crysophanic acid and one part of gutta-percha in eight parts of chloroform, and the preparation so prepared has been also used with success by Dr Fournier Dr Besnier, however, prefers to apply first a solution of crysophanic acid in chloroform, and then to cover this with a varnish of gutta percha in chloroform

His formula is one part of crysophanic acid dissolved in eight or nine of chloroform for the first solution, and one part of purified gutta-percha dissolved in nine of chloroform for the second —*Therap Gazette* July, 1885

ADONIS VERNALIS AND CONVALLARIA MAJALIS —These drugs have been clinically tested by DR GLUZIUSKI (*Przeglad Lekarski*, No 46–49, 1884) as to their claim of being substitutes for digitalis Both drugs were given in the form of an infusion, and to meet the usual indications of digitalis In cases of insufficient compensation, the regulatory effects of both drugs were very conspicuous, the heart beats became more distinct and quiet, the pulse more tense but less accelerated, the entire cardiac irregularity growing less and less manifest Besides, the ventricles grew smaller and the heart-sounds more distinct The quantity of urine voided rose from 300 to 2,000 and 3,000 c c The symptoms of dropsy receded or disappeared wholly The subjective symptoms likewise visibly improved, especially the dyspnœa and palpitation of the heart Compared with digitalis, the latter seems to act more promptly than adonis, and this again excels convallaria In some cases digitalis was clearly useless, while these substitutes acted satisfactorily It is both interesting and valuable to know that, provided a few doses of digitalis were given before the substitutes, these showed an intensity of action far superior to the power of digitalis Both remedies are free from cumulative effects, and are hence very eligible for a protracted use, or in patients that lack medical control —*Therap Gazette*, July, 1885

MEDICINE

PEDIATRIC APHORISMS —The following aphorisms of PROF LETAMENDI are quoted in *El Dictatum*, of May 10, 1884

1 Children are like the mob, they always complain with reason, although they cannot give the reason why they complain

2 Always look at the lips of a pale and sickly child, if they are of a deep red color, beware of pre-

scribing tonics internally. At the outset you will congratulate yourself, but in the long run you will repent of having employed them.

3. As a general rule, a sad child has an encephalic lesion, a furious child, an abdominal one, a soporific child has both, though indistinctly defined.

4. An attendance on children produces on the mind of an observant physician the conviction that the half, at least, of adult transgressors are so through morbid abdominal influences.

5. A sunny living room, a clear skin, and an ounce of castor oil in the cupboard, these are the three great points of infantile hygiene.

6. To dispute the clinical value of tracheotomy in croup is a waste of time to no good purpose. Croup, or no croup, if there be a positive obstruction to respiration in the larynx it is but according to reason to open a way for sub-laryngeal respiration. In the days of more knowledge and less nonsense tracheotomy will be ranked among minor surgical operations.

7. Dentition is the true multiple pregnancy in which the uterus and its fœtuses become petrified in proportion as they grow. It is not the direct or the eruptive pressure, but the lateral pressure of all together that is the most dangerous. It is from this that so many cerebral symptoms appear which can in no way be relieved by incisions of the gums. The only resource against the danger of this transverse pressure is to give the child more nourishment, in the hope that as the general condition is bettered the local condition will also improve.

8. If the incisors of the first dentition are serrated it is bad, but if those of the second formation are the same it is worse. It foretells a number of lesions arising from the deficiency of mineral salts in the tissues. There is only one exception, and it is an important one. When the serrated incisors are seen in the strong children in whom the fontanelles have closed early, it is a sign of robust constitution. Instead of a number of small and sharp dentitions there are a few large blunt ones.

9. To regard the eruption of the teeth as the sole factor in the general process known as the first dentition, is to perpetrate a set of medical synecdoche. Children get their first teeth because they are at the same time getting a second stomach and second intestines.

10. The body of a child possesses such a degree of "acoustic transparency" that in cases of necessity or convenience, auscultation may be practised with the hand, converting it into a telephone which will reveal as much to the physician as even his ear could do.

11. In practise it is well to distinguish with decision a case in which disease is due to lumbricoids from one in which lumbricoids are due to disease. For in the former case anthelmintics are of service, but in the latter they do harm.

12. Since, until a child is able to talk clearly, his relations with the physician are clearly objective, it is very necessary that he should study as carefully as do the veterinarians the exact correspondence between lesions and the expression of the patient.

13. If you wish to cure rapidly and well joint disease in infants, you must treat them as you would a conflagration—douches, douches, and more douches, until you have succeeded in extinguishing them.

14. The entire system of the moral relation between children and adults should be changed. To speak to them incorrectly merely because they cannot pronounce well, to excite their fears and arouse their weird imaginations simply because they are easily frightened and impressionable, to stimulate their vanity because they are naturally inclined to be vain, these and other similar actions are not only wrong but absurd.

15. There is, finally, a danger to women of contracting a vice as yet unregistered in the annals of concupiscence—mastomania, or the sensuality of nursing. When this physiological act degenerates into a vice, nursing becomes so frequent as to be almost continuous, and the result is ruin to both mother and child. Finally, the physician must here, as always, be at once wise, discreet, of good judgment, and firm.—*Birmingham Med. Review*, Aug., 1885.

A NEW METHOD OF GIVING A BATH IN TYPHOID FEVER.—In an article on this subject PROFESSOR H. C. WOOD says: As is well known, the great difficulty in the use of the bath in fevers is the trouble which is involved in moving the patient in and out of the bath tub. The following simple device will in great part remedy this trouble and also save the necessity of providing a portable bath tub. The canvas of an ordinary bed-cot is to be made three or four inches wider than it is ordinarily arranged, and a broad board nailed at each end so as to hold the cot permanently open and project above it several inches in the form of a head or foot board. This cot is then arranged alongside the bed of the patient so as to be on a level with the bed, and at the same time firm. Over it is spread an india-rubber cloth sufficiently large to cover it entirely and to fall above and below over the head and foot-board. The patient, wrapped in a sheet, is then slipped on to the cot, of course the canvas sags down, and when water is poured over the sheet the man lies half immersed in a pool. If the attendant is provided with two tubs, one containing water and one empty, and also with a large bathing-sponge, the water in this pool heated by the body can be removed by means of the sponge, and fresh cold water soused over the body enveloped in the sheet. In this way the water lying continually between the sheet and the body as well as saturating the sheet so envelops the person that the effect of a cold bath can be achieved, and I have seen very rapid reduction of obstinate high temperatures. If the bed upon which the patient lies be a very wide one, instead of a cot being used, the mattress can be so arranged on one side as to sag down sufficiently to form a hollow for the pool, and in this way the bath be given.

I notice that Stephan, of St. Petersburg, affirms that the application of ice-bags over the super-clavicular regions is sufficient to control the temperature in fever, owing to the fact that the cold is brought into close contact with much of the blood of the body by the large superficial veins of the neck. I have had no experience, however, of this method of reducing temperature, but it is worthy of a trial, especially as it seems to be safer to reduce temperature in low fever by external cold than by our at present known depressant antipyretic drugs.—*Therapeutic Gazette*, July, 1885.

TREATMENT OF AN ACUTE FORM OF DIARRHŒA.—DR. JOHN KENT SPENCER, in a note on this subject, says that an eliminative dose of castor-oil, or of Gregory's powder (pulvis rhei compositus) has been usually considered as an essential feature in the preliminary treatment of ordinary diarrhœa. But the management of this common malady, alvine catarrh, has never been raised to the scientific level of many diseases of rarer occurrence, and hence there is always a little uncertainty in our prognosis.

In the *Practitioner* for March, 1875, a formula was published by Dr. David Young of Florence, which I have used ever since with the greatest advantage. He combined about two minims of castor oil with three or four minims of solution of hydrochlorate of morphia (*British Pharmacopœia*), and rubbed them into an emulsion with gum acacia. To this were added spirits of chloroform, and a little syrup. These were the quantities for a single dose, which might be repeated every hour, or every two hours, according to the urgency of the case. If the diarrhœa were chronic, the quantity of castor oil was increased; if there were much pain, more morphia was prescribed.

I have found Dr. Young's mixture extremely valuable for nearly all forms of sudden and acute diarrhœa, such as we see often enough during August and September, and it is scarcely less useful in treating some chronic conditions of irritable bowel which have baffled the so called routine remedies with which we are all familiar. But when the castor oil and morphia fail, or do little good after four or five doses, it may even aggravate the malady to continue them.

Warm milk and lime-water is the best food; a mustard poultice may be put on over the stomach, and there should be absolute rest in bed.—*Brit. Med. Jour.*, Aug. 8, 1885.

SURGERY

COCAINE IN VENEREAL AND SYPHILITIC DISORDERS.—The experience of BONO with cocaine in affections of the genital system (as published by the *Gazz. delle Cliniche*, 1, 1885) can be conveniently epitomized as follows:

1. An injection of a few drops of a two per cent. solution of cocaine removes promptly the pains felt in acute gonorrhœa during micturition and erection. The injection has to remain in the urethra for at least five minutes, and to be repeated four to five times daily.

2. This cocaine injection is unrivalled in rendering caustic injections or the introduction of the catheter painless.

3. The burning pains of blennorrhœa in women yield invariably to small cotton tampons saturated with a two per cent. solution of cocaine, or to the application of a five per cent. solution of cocaine or to the application of a five per cent. cocaine ointment.

4. Cocaine facilitates the examination of urethra and bladder with the bougie and the endoscope.

5. It allows of a painless cauterization in bulano prostatitis.

6. Pointed condylomatæ can be painlessly cauterized, excised, or scraped out with its aid.

7. In cauterization and excision of primary syphilitic affections, cocaine evinced very desirable analgesic virtues of a sufficiently long duration.

8. Taken internally during an antisyphilitic treatment, cocaine did not present any appreciable effects.

9. Its local effects are highly beneficent in syphilitic tonsillitis and in stomatitis mercurialis, and difficulties of deglutition.

Bono refers also to its analgesic properties in acute painful eczema, pruritus vulvæ, sore nipples, and burns.

As Bono's observations were confirmed by Blumenfeld, Frankel, Pick, and Neisser, they are entitled to attention and confidence.—*Therapeutic Gazette*, June, 1885.

COCAINE IN URETHRAL CARUNCLE.—DR. PERCY BOULTON finds, in cases of "urethral caruncle" (those exquisitively sensitive growths of the female urethra), that the effect of cocaine is marvellous. Few small troubles are more sensitive to touch, and formerly it was necessary to give chloroform for their removal. He applies a four per cent. solution of cocaine, and in five minutes snips them off with sharp scissors, and applies the cautery to the stump to stop bleeding, without chloroform, and without pain to the patient. The same solution, if applied in the nostrils with a camel's hair brush, undoubtedly produces great relief in cases of hay fever.—*British Medical Journal*, July 25, 1885.

OBSTETRICS AND GYNÆCOLOGY

DIAPHORETIC TREATMENT OF PUERPERAL ECLAMPSIA BY HOT BATHS.—DR. BREUS reports (*Archiv fur Gynakolog.*, xxi. 1.) eleven cases of puerperal eclampsia treated by the hot bath with ten recoveries. He had previously treated six cases by this method, losing in this series, likewise, one case. He first places the patient in a bath of 100° F., and gradually increases the temperature from two to four degrees. He then envelops the patient in blankets to excite an abundant diaphoresis. Of these eleven women, four had had convulsions at the commencement of labor, two during gestation, one at the moment of delivery, and four after delivery. The author affirms, from his experience with these seventeen cases, that neither abortions nor hemorrhages are to be feared from the employment of the bath, and that when the presence of albumen in the urine indicates a threatened complication, the bath constitutes an excellent prophylactic means. One of these cases reported was that of a primipara, aged twenty six, who was attacked with œdema and albuminuria. In the eighth month baths began to be given. After taking forty-five, she was successfully delivered of a large and healthy child.—*Medical Record*, Aug. 15, 1885.

THE AMERICAN MEDICAL ASSOCIATION AND THE CONGRESS OF 1887

Perhaps the action of no organized body of men was ever before so extensively and persistently misrepresented, as that of the American Medical Association at its meeting in New Orleans, regarding the preliminary organization of the International Medical Congress of 1887 Instead of wasting time and space in enumerating and refuting these misrepresentations in detail, we will oppose to them all, the following simple statement of historical facts

1st At the preceding annual meeting in Washington, May, 1884, on the recommendation of the President Professor Austin Flint, of New York, endorsed by the report of a Special Committee of which Dr J S Billings of Washington, I Minis Hays, of Philadelphia, and Lewis A Sayre, of New York, were members, the Association was induced to adopt resolutions presented by said Special Committee, authorizing the President of the Association to appoint a Committee of Seven, of which he should be a member which Committee should attend the International Medical Congress to be held a few months later in Copenhagen, and in behalf of the *profession of the United States*, extend an invitation for the next triennial meeting to be held in this country If the invitation was accepted, the same series of resolutions conferred upon the same Committee authority to add to its number and exercise all the powers of a Committee of Arrangements for effecting the preliminary organization of the proposed Congress, with an appropriation from the Treasury of the Association to defray necessary preliminary expenses The Committee thus authorized was appointed by the President and consisted of Drs J S Billings, Austin Flint, (ex officio) I Minis Hays, J M Browne, L A Sayre, Christopher Johnson, S J Engelman, to which was added Dr H F Campbell as President elect of the Association The fact that this Committee of Invitation had been appointed by the American Medical Association, which by such appointment had made itself responsible for the acts of such Committee in carrying out the instructions contained in the resolutions was published in all the leading Medical Journals and could not have been otherwise than well known in Europe In due time the invitation was extended by the Committee and formally accepted in open session of the Congress in Copenhagen The Committee returned home invited sixteen other prominent members of the profession to unite with them, constituting a General Committee of twenty five This General Committee held one meeting in Washington, organized by the election of a President, Vice-Presidents, Secretary-General, and Treasurer Rules were also adopted for the organization of the Congress, one of which made the Officers of the Committee also the General Officers of the preliminary organization of the Congress At the same meeting some of the Officers of Sections were appointed, and further details of the work were committed to an Executive Committee of five, subject to the approval of the General Committee The Executive Committee by conferences of its own and by correspondence with other members, so far completed the work of organization as to publish the results both in this country and Europe only a few weeks before the annual meeting of the Association in New Orleans, the last week in April, 1885

2d At the meeting of the Association in New Orleans, Dr J S Billings, as the Secretary-General of the proposed Congress, made a brief report of the doings of the Committee and presented a printed copy of the Rules and Official Organization adopted The report was received and made the special order for consideration the following day At the hour appointed, several members freely criticised the work of the Committee, pointing out the fact that it had appropriated all the chief offices of the Congress to its own members, that it had centered an unduly large proportion of the Officers of Sections in two or three cities, instead of making them representative of the profession of the United States in whose name the invitation had been given, and had given undue prominence to a particular portion of the profession in New York, which was well known to have arrayed itself in opposition to the State and National organizations of the profession generally The result of the discussion was the adoption of two resolutions by the Association, both of which have been repeatedly published in the columns of this JOURNAL, the effect of which was clearly to make the Committee on Organization more national in character, or, in other words, more directly representative of the profession of the United States by adding to the Original Committee of eight one from the profession of each State and Territory, in the place of the additions previously made by the Original Committee and to give the Committee thus enlarged authority to review the work previously done by the Committee on Organization, and make such changes as the enlarged Committee might think advisable. This was the sum total of the action of the American Medical Association concerning the organization of the Congress. The resolutions adopted contain not one word about Codes of Ethics, they displace no one of the Original Committee, they prescribe no rule either for the membership, government or officering of the Congress but simply enlarge the Original Committee in such a way as to make it more representative of the whole profession, and continue in the enlarged Committee the same powers substantially, as were conferred upon the Original Committee at the meeting in Washington.

3d. The Committee as enlarged by the action of the Association in New Orleans held its first meeting in Chicago June 24 and 25, 1885, and organized simply as a Committee of Arrangements, its officers having no corresponding positions in the proposed Congress as had been the case with the first organization of the Committee. After as full an examination of the work previously done as the time would permit, the Committee re-adopted nearly all the Rules previously devised except those relating to the American Membership and the Executive Committee of the Congress. The first of these it was proposed to amend in such a way as to unnecessarily restrict the membership, and all provision for the latter was overlooked. In consequence of these defects, the proper work of the Committee was continued, and a second general meeting held in New York, Sept. 3 and 4, 1885, during which the revision of the Rules was completed, the vacancies in the general offices of the preliminary organization of the Congress filled, and an Executive Committee provided for, consisting of the President of the Congress, the Secretary-General, the Treasurer, the Chairman of the Finance Committee, and the Presidents of the several Sections. The Committee of Arrangements thus deliberately completed the work assigned to it by the Association, and delegated to the Executive Committee of the Congress full power to fill all future vacancies, complete all unfinished details of organization, increase to a limited extent the number of its own members, and manage all the affairs of the Congress in accordance with the Rules adopted, without other restraint or interference from any source. The Rules in detail, together with the General Officers of the Congress, the Presidents of Sections, and the Executive Committee, were published in this JOURNAL for Sept. 12, 1885.

We have given the foregoing plain narrative of facts regarding the action of the American Medical Association and its Committee of Arrangements for providing a preliminary organization for the International Medical Congress of 1887, which would fairly represent the medical profession of the United States, and under rules as liberal, in relation to membership and in all other respects as those adopted by previous Congresses, to show, first, how utterly groundless have been the charges and denunciations so persistently hurled at the Association and its Committee; and, second, that notwithstanding all the persistent opposition of a few prominent members of the profession having control of three or four leading medical journals, the Association, through its enlarged and representative Committee, has fulfilled the obligations it incurred in inviting the Congress to hold its next meeting in the City of Washington in 1887, by effecting a preliminary organization on a national and liberal basis, with ample power to manage all the business and scientific interests of the Congress as independently as the interests of any previous Congress has been managed in Europe. The responsibility is now with the new Executive Committee and the true friends of the Congress everywhere. If the Committee will take up its work promptly and push it harmoniously, it will receive ample support both at home and abroad, and the Congress will be as successful as the most enthusiastic could desire.

THE TREATMENT OF ACUTE INTESTINAL OBSTRUCTION.

Three valuable papers were read on this subject at the recent annual meeting of the British Medical Association, all of which are published in the *British Medical Journal*, of August 29. MR. FREDERICK TREVES, who has added so much to the literature of intestinal obstruction, introduced a discussion on the subject with a paper entitled "The Operative Treatment of Intestinal Obstruction," and was followed by MR. J. GREIG SMITH, and MR. A. W. MAYO ROBSON. Two other papers, of considerable interest in connection with this subject were also read at the meeting, by MR. R. N. PUGH, who reported a successful case of operation for intestinal obstruction, in a child six years of age, and MR. E. STANMORE BISHOP, who read a paper on "Enterorrhaphy, with a description of a New Form of Suture."

Mr. Treves opens his paper with the regret that "Intestinal Obstruction" has a place in surgical nomenclature. It would be as reasonable, he thinks, "to consider retention of urine as a distinct and isolated malady, without recognizing that it may depend upon a stricture of the urethra in one case, and an impacted calculus in another." In this paper he discusses only the acute form of intestinal obstruction, and for convenience gives the collection of symptoms making up the condition known as acute intestinal obstruction as being due to (1) hernia-like strangulation of the bowel, (2) volvulus of the sigmoid flexure, and (3) acute invagination: which he discusses in turn.

With regard to the first form, "in every instance, a knuckle or loop of bowel is held and kept in bondage until it is strangulated. The mechanism of the obstruction is in all main points identical with that of strangulated external hernia, the general pathology is the same, and, with some minor modifications, the symptoms are the same." Mr. Treves would put the patient to bed, and keep him at absolute rest, relief of the abdominal pain being attempted by warm applications to the belly. Opium is given to ensure rest to the bowel, and food is absolutely interdicted. The thirst may be relieved by sucking ice, or by hot tea. The colon should be emptied by enemata. In the matter of surgical treatment he recommends that laparotomy be performed within the first twenty-four hours, if the diagnosis be clear. And he again calls attention to the fact, so often insisted upon, that laparotomy is not in itself a dangerous operation, but that its present rather high mortality is due to its being regarded as a last resort rather than a first, or early means of relief." It seems to be tampering with life to waste time over the administration of metallic mercury, and enemata of tobacco and the like. To thrust an aspirator into the abdomen, as some advise, is a stab in the dark, an empirical proceeding that leaves everything to chance. As regards the operation itself, it need only be said that Mr. Treves is a firm believer in Listerism, that he advocates a clean cut in the linea alba, below the umbilicus, and does not use "that uncouth weapon, the steel director."

In the treatment of acute volvulus of the sigmoid flexure, Mr. Treves says: "I take it that, in the first instance, the treatment by rest and starvation would be insisted on as a matter of routine. Opium would be administered, and it may be as well to empty the rectum by an enema. With regard to more active interference, I believe that all attempts at relief by enemata or rectal tubes are likely to prove not only quite useless, but actually harmful. If the precise relation of the parts be borne in mind, it will be perceived that a forcible injection into the rectum will tend to tighten rather than to relax the twist." Of operation for this form of obstruction he says that simple laparotomy is an unpromising precedure, but in any future case he will perform laparotomy in the middle line, puncture the gut, and attempt its reduction; if this fail, or the result appear unsatisfactory, he will evacuate the involved gut through an opening in the summit of the flexure, unfold the volvulus, and establish an artificial anus, using the opening just mentioned for that purpose. "By this method, the volvulus could be relieved in a very short space of time, and without much handling; and the distended colon above the twist could empty itself through the artificial anus. Inasmuch as this artificial opening would be at the summit of the sigmoid flexure, a return of the volvulus would be impossible." But however the operation be performed, it should be done quickly, on account of the rapidity with which peritonitis sets in, and the great risk of the involved loop becoming gangrenous.

If, after twelve hours of treatment of acute intussusception with opium or belladona and starvation and rest, "it will be expedient to attempt reduction by means of insufflation or forcible enemata." He thinks that in children under ten years of age the injection should be cautiously administered while the child is under the influence of an anæsthetic, but that in adults the best guide to force is the patient's own sensation. The injection—whether of air or water—should be retained for at least twenty minutes, gentle kneading of the intussusception being practised while the injection is retained. On no account should this treatment be adopted before the bowel has been placed at rest by means of opium or belladonna. These measures should be resorted to within the first twenty-four hours, if possible, in order that laparotomy may be performed early. After the operation, should the invagination be irreducible resection of the whole involved portion should be performed, and a temporary artificial anus be established. Mr. Treves does not think enterotomy a suitable operation in these cases." It will relieve the obstructive symptoms, it is true, but it will leave the invagination untouched, and leave it possibly to pass on into a state of gangrene, or a condition that may lead to diffuse peritonitis."

Mr. J. Greig Smith, in his paper, dwells chiefly on edly published in the columns of this JOURNAL, the effect of which was clearly to make the Committee on Organization more national in character, or, in other words, more directly representative of the profession of the United States, by adding to the Original Committee of eight one from the profession of each State and Territory, in the place of the additions previously made by the Original Committee, and to give the Committee thus enlarged authority to review the work previously done by the Committee on Organization, and make such changes as the enlarged Committee might think advisable This was the sum total of the action of the American Medical Association concerning the organization of the Congress The resolutions adopted contain not one word about Codes of Ethics, they displace no one of the Original Committee, they prescribe no rule either for the membership, government, or officering of the Congress, but simply enlarge the Original Committee in such a way as to make it more representative of the whole profession, and continue in the enlarged Committee, the same powers, substantially, as were conferred upon the Original Committee at the meeting in Washington

3d The Committee as enlarged by the action of the Association in New Orleans held its first meeting in Chicago, June 24 and 25, 1885, and organized simply as a Committee of Arrangements, its officers having no corresponding positions in the proposed Congress, as had been the case with the first organization of the Committee After as full an examination of the work previously done as the time would permit, the Committee re-adopted nearly all the Rules previously devised except those relating to the American Membership and the Executive Committee of the Congress The first of these it was proposed to amend in such a way as to unnecessarily restrict the membership and all provision for the latter was overlooked In consequence of these defects, the proper work of the Committee was continued, and a second general meeting held in New York, Sept 3 and 4, 1885, during which the revision of the Rules was completed, the vacancies in the general offices of the preliminary organization of the Congress filled, and an Executive Committee provided for, consisting of the President of the Congress, the Secretary-General, the Treasurer, the Chairman of the Finance Committee, and the Presidents of the several Sections The Committee of Arrangements thus deliberately completed the work assigned to it by the Association, and delegated to the Executive Committee of the Congress full power to fill all future vacancies, complete all unfinished details of organization, increase to a limited extent the number of its own members, and manage all the affairs of the Congress in accordance with the Rules adopted, without other restraint or interference from any source The Rules in detail, together with the General Officers of the Congress, the Presidents of Sections, and the Executive Committee, were published in this JOURNAL for Sept 12, 1885

We have given the foregoing plain narrative of facts regarding the action of the American Medical Association and its Committee of Arrangements for providing a preliminary organization for the International Medical Congress of 1887, which would fairly represent the medical profession of the United States, and under rules as liberal, in relation to membership and in all other respects as those adopted by previous Congresses, to show, first, how utterly groundless have been the charges and denunciations so persistently hurled at the Association and its Committee, and, second, that notwithstanding all the persistent opposition of a few prominent members of the profession having control of three or four leading medical journals, the Association, through its enlarged and representative Committee, has fulfilled the obligations it incurred in inviting the Congress to hold its next meeting in the City of Washington in 1887, by effecting a preliminary organization on a national and liberal basis, with ample power to manage all the business and scientific interests of the Congress as independently as the interests of any previous Congress has been managed in Europe The responsibility is now with the new Executive Committee and the true friends of the Congress everywhere If the Committee will take up its work promptly and push it harmoniously, it will receive ample support both at home and abroad, and the Congress will be as successful as the most enthusiastic could desire

THE TREATMENT OF ACUTE INTESTINAL OBSTRUCTION

Three valuable papers were read on this subject at the recent annual meeting of the British Medical Association, all of which are published in the *British Medical Journal,* of August 29 MR FREDERICK TREVES, who has added so much to the literature of intestinal obstruction, introduced a discussion on the subject with a paper entitled "The Operative Treatment of Intestinal Obstruction," and was followed by MR J GREIG SMITH, and MR A W MAYO ROBSON Two other papers, of considerable interest in connection with this subject were also read at the meeting, by MR R N PUGHE, who reported a successful case of operation for intestinal obstruction, in a child six years of age, and Mr E. Stanmore Bishop, who read a paper on "Enterorrhaphy, with a description of a New Form of Suture."

Mr Treves opens his paper with the regret that "Intestinal Obstruction" has a place in surgical nomenclature. It would be as reasonable, he thinks, "to consider retention of urine as a distinct and isolated malady, without recognizing that it may depend upon a stricture of the urethra in one case, and an impacted calculus in another." In this paper he discusses only the acute form of intestinal obstruction, and for convenience gives the collection of symptoms making up the condition known as acute intestinal obstruction as being due to (1) hernia-like strangulation of the bowel, (2) volvulus of the sigmoid flexure, and (3) acute invagination, which he discusses in turn.

With regard to the first form, "in every instance, a knuckle or loop of bowel is held and kept in bondage until it is strangulated. The mechanism of the obstruction is in all main points identical with that of strangulated external hernia, the general pathology is the same, and, with some minor modifications, the symptoms are the same." Mr Treves would put the patient to bed, and keep him at absolute rest, relief of the abdominal pain being attempted by warm applications to the belly. Opium is given to ensure rest to the bowel, and food is absolutely interdicted. The thirst may be relieved by sucking ice, or by hot tea. The colon should be emptied by enemata. In the matter of surgical treatment he recommends that laparotomy be performed within the first twenty-four hours, if the diagnosis be clear. And he again calls attention to the fact, so often insisted upon, that laparotomy is not in itself a dangerous operation, but that its present rather high mortality is due to its being regarded as a last resort rather than a first, or early means of relief." It seems to be tampering with life to waste time over the administration of metallic mercury, and enemata of tobacco and the like. To thrust an aspirator into the abdomen, as some advise, is a stab in the dark, an empirical proceeding that leaves everything to chance. As regards the operation itself, it need only be said that Mr Treves is a firm believer in Listerism, that he advocates a clean cut in the linea alba, below the umbilicus, and does not use "that uncouth weapon, the steel director."

In the treatment of acute volvulus of the sigmoid flexure, Mr Treves says: "I take it that, in the first instance, the treatment by rest and starvation would be insisted on as a matter of routine. Opium would be administered, and it may be as well to empty the rectum by an enema. With regard to more active interference, I believe that all attempts at relief by enemata or rectal tubes are likely to prove not only quite useless, but actually harmful. If the precise relation of the parts be borne in mind, it will be perceived that a forcible injection into the rectum will tend to tighten rather than to relax the twist." Of operation for this form of obstruction he says that simple laparotomy is an unpromising precedure, but in any future case he will perform laparotomy in the middle line, puncture the gut, and attempt its reduction; if this fail, or the result appear unsatisfactory, he will evacuate the involved gut through an opening in the summit of the flexure, unfold the volvulus, and establish an artificial anus, using the opening just mentioned for that purpose. "By this method the volvulus could be relieved in a very short space of time, and without much handling, and the distended colon above the twist could empty itself through the artificial anus. Inasmuch as this artificial opening would be at the summit of the sigmoid flexure, a return of the volvulus would be impossible." But however the operation be performed, it should be done quickly, on account of the rapidity with which peritonitis sets in, and the great risk of the involved loop becoming gangrenous.

If, after twelve hours of treatment of acute intussusception with opium or belladona and starvation and rest, "it will be expedient to attempt reduction by means of insufflation or forcible enemata." He thinks that in children under ten years of age the injection should be cautiously administered while the child is under the influence of an anæsthetic, but that in adults the best guide to force is the patient's own sensation. The injection—whether of air or water—should be retained for at least twenty minutes, gentle kneading of the intussusception being practised while the injection is retained. On no account should this treatment be adopted before the bowel has been placed at rest by means of opium or belladonna. These measures should be resorted to within the first twenty-four hours, if possible, in order that laparotomy may be performed early. After the operation, should the invagination be irreducible resection of the whole involved portion should be performed, and a temporary artificial anus be established. Mr Treves does not think enterotomy a suitable operation in these cases." It will relieve the obstructive symptoms it is true, but it will leave the invagination untouched, and leave it possibly to pass on into a state of gangrene, or a condition that may lead to diffuse peritonitis."

Mr J. Greig Smith, in his paper, dwells chiefly on two points in the operative procedure in which he is at variance with Mr Treves, and which he states as follows (1) The best guide to the seat of operation is not manual exploration, but visual examination, assisted, if necessary, by extrusion of bowel (2) No case of operation for intestinal obstruction is properly concluded until distended bowels are relieved of their contents Mr Smith has no scruples against examining the intestines visually, and declaims against attempts to diagnosticate the condition of the bowel by examination with the hand alone He would "substitute the finger for the hand, and supplement both by the sight, I would ignore the cæcum, I would permit the bowel to extrude if it were much distended, I would even encourage it to do so, if I had not at once discovered the seat of obstruction, and if its extrusion were any help to me in this discovery, and I would go through all this before I inserted my hand to grope for the cause" He regards it as only less than a surgical calamity to perform median laparotomy for obstruction in the colon, since in the majority of cases it must, he says, be supplemented by a transverse or lumbar incision

In regard to the second point in which he differs from Mr Treves, he is quite certain that the presence of an excess of intestinal contents is in itself a cause of obstruction—an opinion that is supported by the physical characteristics of the intestines For the removal of these contents he is inclined to think that the method recently brought prominently forward by Kussmaul is likely to prove of great value It is well known that vomiting relieves these cases, and Kussmaul, by repeated applications of the stomach-pump, empties the intestines of their fluid and gaseous contents, relieving the patient, and frequently effecting a cure Directly contrary to the opinion of Mr Treves, he places great weight on enterotomy, or enterostomy, believing that it is applicable in almost every form of intestinal obstruction If neither Kussmaul's operation nor enterostomy satisfactorily relieve the distension, he would proceed to incision and immediate suturing, if this does not suffice he would make an artificial anus

Of Mr Robson's paper we can only give his general conclusions, which are based on his own experience, on *post mortem* records, and on recorded cases

1 In chronic cases—that is, where obstruction is the prominent symptom—medical treatment, such as injection, belladonna, massage, galvanism, etc, will often relieve or cure, or colotomy or laparotomy, or some other operation will be so plainly indicated as to leave no doubt as to what should be done

2 In acute symptoms supervening on chronic, medical treatment—for example, starvation rest and opium—may still often bring about a cure but laparotomy, as a means of diagnosis, and possibly of treatment, may be demanded

3 In initially acute cases, delay is often as dangerous as it would be to wait for an external hernia to reduce itself by its own efforts

"I believe that laparotomy (which in itself is not a dangerous operation) should be performed early—(*a*) as a means of making a diagnosis, (*b*) as a means of removing the cause of strangulation if such be discovered, (*c*) as a means of giving relief, if no cause can be found, by opening the bowel above the point of obstruction and carefully suturing it to the surface"

DR FELSENREICH'S MODIFICATION OF ALEXANDER SIMPSON'S AXIS TRACTION FORCEPS

Why so much obloquy should attend the obstetrical forceps throughout its intricate history, it is difficult to say In 1723, Johann Palfyn, the surgeon of Ghent, presented to the Academy of Paris a crude obstetrical forceps, termed *manus ferreæ Palfynianæ* About the same time, De la Motte heard rumors of the existence of a more perfect instrument He rejected the possibility of the obstetrical forceps, but sagely added, that if such a thing could be true—seeing that it was false—and the inventor should die without publishing his invention, he deserved that a vulture should prey upon his entrails throughout eternity For seventy-five years, such an instrument had existed, and was the family secret of the Chamberlens From its invention by Peter Chamberlen (born 1601, died 1683), every modification of the forceps has been the subject of bitter contention In very recent times, we have been compelled to listen to Tarnier's heated polemics

Dr L E Neale, of Baltimore, publishes an article entitled "An Obstetric Forceps," in the September number of the *American Journal of Obstetrics*, which deserves particular attention After referring to the superiority of Simpson's forceps for easy cases, and the importance of Tarnier's principle of axis-traction, Dr Neale says "For these reasons principally, I have designed an instrument representing the Simpson forceps practically unaltered, capable of being combined at option with the Tarnier attachment" Dr Neale's instrument, as presented to the Medico-Chirurgical Faculty of Maryland, at its meeting in Baltimore, in 1885, consists of the following parts "I A practically unaltered Simpson's forceps II The button hole perforations, one behind each fenestra, into which traction rods are inserted and maintained by the buttons on the ends of the rods III A removable compression thumb screw which sinks into a groove made in the extremities of the handles of the Simpson forceps IV The hard rubber handle for the traction rods, like Tarnier's, in which handle is concealed a sliding bar, to be used at option, so as to render the swivel joint immovable "

The advantages of such an instrument are obvious With the single exception of the compression thumb screw at the extremities of the handles, it is an approximately perfect mechanical contrivance But the instrument, with the exception of the thumb screw, has been in active use in Vienna, since 1881–'82 Professor Alexander Simpson modified Tarnier's axis-traction forceps by the substitution of Sir James Y Simpson's forceps for Levret's This modification was published about the year 1880, and was preferred in Vienna to Tarnier's most recent model Dr Felsenreich, at that time first assistant to Professor Carl Braun, modified the Alexander Simpson instrument by the addition of the button hole joint Dr Felsenreich's instrument is thus identical with the forceps described by Dr Neale, with the exception of the thumb screw The compression screw in Dr Felsenreich's instrument is located on the middle third of the superior surface of the handles, as in the Alexander Simpson instrument With characteristic modesty, Dr Felsenreich has refrained from publishing a description of his modification, until it could be thoroughly tested The instrument, however, is used in the clinic, exhibited in the courses on operative obstetrics, and is for sale by Mr J Leiter, in Vienna Dr Neale saw this instrument employed in Vienna, and his allusion to the fact is disingenuous He says "The idea of its construction is not *entirely* original with me, as the button hole joint for the traction rods was first shown to me by Dr Felsenreich, first assistant to Prof Carl Braun, of the Vienna Clinic, in 1882 " Dr Neale is entitled to the honor of substituting the compression thumb screw at the ends of the handles for the more useful contrivance of the Felsenreich and Alexander Simpson instruments So far, we have been dealing exclusively with facts

It is not our purpose to allude to matters of opinion Dr Neale is favorably known as a zealous student of obstetrics He has placed the American and English profession under lasting obligation for his excellent translation of Pinard's brochure, on "Abdominal Palpation as Applied to Obstetrics " It is quite possible that the error in the paper, to which we have ventured to call attention, may be explained by the unconscious persistence of mental impressions

SOME DIFFERENCE —In commenting on the action of the Committee of Arrangements at its recent meeting in New York, The *Medical Record* says "The Committee have utterly eliminated and blotted out Drs Cole and Shoemaker, trusting, we presume, to gain back Philadelphia by thus making scapegoats of these gentleman " But the *Medical News* of the same date parades Drs Cole and Shoemaker with the whole Committee of which they are officers, in its columns as constituting the "General Committee" of the Congress, while it entirely omits the true General Executive Committee of that organization As usual both are wrong, and both endeavoring to perpetuate dissentions and errors "Whatsoever a man soweth that shall he also reap "

SOCIETY PROCEEDINGS

MISSISSIPPI VALLEY MEDICAL SOCIETY
(Formerly Tri-State)

Eleventh Annual Meeting, held in Evansville Ind, Sept 8th 9th, and 10th, 1885

TUESDAY, SEPT 8 —MORNING SESSION

THE PRESIDENT, DR F W BEARD, OF VINCENNES, IND, IN THE CHAIR

DR A M OWEN, of Evansville, Chairman of the Committee on Arrangements, made his report He said that the meeting had been very thoroughly advertised in the journals, and that 5,000 circulars had been sent out He explained the arrangements he had made with the railroads and hotels Report accepted

The Chair appointed Drs Chas Knapp, of Evansville, Ind, Helm of Henderson, Ky, and Edward Borck, of St Louis, as Committee on Credentials

The reading of the minutes of the previous meeting was dispensed with

The Committee on Publication reported that all papers which had come into their hands had been published as required in the organ of the Society A few papers had been published in Chicago and elsewhere The Committee thought it desirable that the papers be published promptly One paper was not published for four months after it was read

DR G W BURTON moved that a Committee on Publication be appointed by the Chair Adopted The Chair appointed Drs G W Burton, of Mitchell, Ind, A M Owen, of Evansville, Ind, and H J B Wright, of Olney, Ill

DR J E SUTCLIFFE, of Indianapolis, read a paper entitled

A CASE OF PERINEAL SECTION WITHOUT A GUIDE FOR STRICTURE OF THE URETHRA

Called to see John D, æt 56, Irish Found patient suffering from retention of urine Bladder was largely distended, reaching up toward the umbilicus

Dr Arch Dixon, of Henderson, Ky , related

A CASE OF GONORRHŒAL STRICTURE WHERE THE URETHRA WAS GROWN TOGETHER

Dr Joseph Eastman, of Indianapolis, said The paper urges the importance of a thorough knowledge of the perineum This is right, notwithstanding that Dr Bauer speaks lightly of this, and thinks that a distended urethra cannot be missed When we cut into the bladder of a female we relieve her of a suffering from cystitis worse than death Why should we not do so in the male? He thought there was here a field for study and improvement, and urged on those present to consider the matter carefully

Dr A C Bernays, of St Louis, said he thought the question whether or not impermeable stricture existed, was settled We have had two cases, one cicatricial, one gonorrhœal He considered the three operations, thought all were useful, but favored Cox's, or the English operation

Dr Sutcliffe, in closing the discussion, thought that tapping in front of the prostate gland, known as Gunther's operation, was excellent

Afternoon Session

Dr Wm Porter, of St Louis, read a letter addressed to the Society from Dr Morrell Mackenzie, of London, England, regretting his inability to be present, and wishing the Society a pleasant and profitable meeting

Dr Jas H Letcher, of Henderson, Ky , moved that the thanks of the Society be conveyed to Dr Mackenzie for his kind remembrance Passed

[Dr Mackenzie attended the meeting of the Society a few years ago, expressed himself as much pleased with it, and always remembers it]

Dr George Brinton Walker, of Evansville, Ind , read a paper on

PUERPERAL FEVER AND PUERPERAL SEPTICÆMIA

The word comes from *puer*, a child, and *parere*, to bring forth Although modern writers prefer another name in describing this condition, it is probable that the simple title, puerperal fever, will not soon be entirely abandoned The disease was recognized in the earliest antiquities Rachel, the beloved wife of the patriarch Jacob, as well as the wife of Phineas, is supposed to have died of this disease It was mentioned by Hippocrates, the discerning father of medicine First called puerperal fever by Dr Strother, in 1716 It is divided into sporadic and epidemic, or inflammatory and congestive Also divided into synochal, sthenic, or benign or typhoid, as thenic, putrid, or malignant In fatal cases patient dies three to ten days after confinement From eminent authorities we may consider puerperal fever to be an inflammatory disease, some sthenic, some asthenic It generally involves the peritoneum, occasionally the appendages of the uterus and uterine veins and lymphatics The mode of reception of the poison is divided into auto and hetero infection Here the doctor quoted largely from Thomas's recent paper before the New York Academy of Medicine, and the discussion which followed He cited the conflicting testimony of both modern and ancient authors From an impartial consideration of all authors and his own experience the doctor was lead to the following statements

1 That the fever which attacks woman in the puerperal state may consist of numerous and distinct pathological conditions It may be a sthenic disease caused by injury or shock from the passage of the child through the genital tract

2 It may be asthenic, or malignant, from some occult cause associated with the traumaticism of labor

3 It may be the result of toxemia from septic matters entering into and circulating through the vascular system

As to the agency of bacteria, he thought the subject may be regarded as undecided, and inviting further investigation Dr Byford thinks several diseases are included under the denomination of puerperal fever, especially as distinguished by the profession at large There are metritis and metro peritonitis without septic infection In the septicæmic variety treatment consists in relieving, 1st Inflammatory condition, 2d High temperature, 3d Malignant results of septicæmia, 4th Insufficient strength, tone up and stimulate the patient

In the purely inflammatory form the antiphlogistic treatment is indispensable In the malignant variety, opiates, stimulants, stupes externally, and calomel, quinine in 10, 20, 30, 60 grain doses, should be given The doctor, the nurse, and others about the patient should be clean, especially the patient herself He did not think ante-partal antiseptic injections advisable They are not only unnecessary, but really hurtful, by subjecting patient to a painful system of annoyance, which of itself may cause disease It is worse than meddlesome midwifery, because it anticipates labor and does not permit the woman to enjoy necessary rest when labor is completed

Dr S E Munford, of Princeton, Ind , recalled one case which resulted in death He had, the day previously, attended a case of erysipelas He has no doubt that physicians do carry this disease In treatment, the two great remedies are opium and quinine in large doses in the malignant cases

Dr Eastman, of Indianapolis, would insist that obstetric cases must be treated as others He wants to be put on record as saying that a woman should not necessarily lie in bed nine days, but must sit up every day to allow her bed to be thoroughly renovated, and to allow the clots to pass more thoroughly We cannot consider puerperal fever aside from surgical septicæmia He doubts if a woman was ever delivered of a child where an abrasion did not occur, in comparison with which the puncture for vaccination is small An old Irish woman had taught him a lesson by ordering the patient to get up and pass the clot in the chamber Simon recommended giving women more liberty after laceration of the cervix He was opposed to carbolic acid and in favor of the bichloride This latter he dissolved in glycerine, then diluted to 1 400 Ice or warm applications applied to the parts are both beneficial and both act in about the same way He has much faith in quinine

Pulse increased in frequency and temperature 101° F Perineum swollen, tender, and of pinkish hue, patient anxious and restless During his efforts at straining a few drops of urine would dribble away Gave no history of urethral inflammation, but stated that for a long time it had taken him nearly an hour to empty his bladder, the urine passing away by drops External hæmorrhoids were noticed, the result of the straining Found a narrow stricture at the meatus and the adjacent tissue indurated and contracted, also an impermeable stricture at the junction of the bulb with the membranous portion of the urethra and the prostate gland considerably enlarged Not even the finest cat-gut bougie or whalebone guide could be induced to enter the bladder The bladder was tapped above the pubes with an aspirator, and the urine withdrawn On the morning of the second and third days the effort at catheterism was renewed without success, and the urine was removed by the aspirator Fourth day the bladder was again distended and the general symptoms more alarming The extravasated fluid was distending the perineum and infiltrating the areolar tissue of the scrotum Pulse 116, temperature 102°, delirium Perineal section was decided upon in consultation with Dr F S Newcomer With the patient under the anæsthetic another effort was made to pass a guide Failing in this, the stricture at the meatus was freely incised, and Gouley's staff catheter, which is grooved on its posterior surface, was passed down to the front face of the stricture An incision was made through the median line of the perineum through the integument superficial and deep layers of the superficial fascia A pint and a half of pus and urine flowed through the wound The urethra was then opened on the point of the staff and the instrument slightly withdrawn A probe was passed through the stricture, the callous tissue divided, and the staff entered the bladder guided by a groove director introduced through the cut To make sure that no indurated tissue remained undivided, a good sized sound was introduced through the meatus to the bladder No catheter was left in the bladder, and the wound and bacteria were left to take care of themselves The urine flowed freely through the cut and urethra The after treatment consisted of the introduction of the sound every few days in order to maintain the normal calibre of the canal The patient recovered with no unfavorable symptom, but a slight fistula still remains, now eight months, at the point of incision This will close if the urethra is kept open The urine flows freely through the natural tract

After the limited experience of two cases it is the doctor's opinion that the danger of failure is due largely to cutting too freely after the front face of stricture is exposed This is the critical moment when we should rely largely on the probe, and keep in mind the anatomical relation of the parts Extravasated urine from stricture may pass in three directions Most frequently, as in the present case, it makes its way in front of the triangular ligament, distending the perineum and scrotum Should we be content to relieve the extravasation alone, or should we in addition deal with the stricture at the same time? Some eminent authorities claim that to relieve the retention is all that is required, and the stricture may be treated afterwards, and if necessary operated upon In the majority of instances the doctor believes that the stricture should be thoroughly divided at the time the retention is relieved Operation should be made early Rest can do much, but cannot remove the organized fibrous tissue any more than it can absorb the cicatrix of a burn Most patients will consent to but one operation, and it would be cruel not to take advantage of the opportunity and divide the stricture Its division does not add materially to the shock of the operation, and it at once places the patient on the high road to a speedy and perfect recovery

DR BYRD, of Quincy, *Ill*, spoke complimentary of Reginald Harrison's recent lecture before the British Medical Association at Cardiff,

ON URETHRAL STRICTURE

He recommended external urethrotomy as the safest operation, and gave his experience in the two hospitals at Quincy He had not found impermeable stricture, and believes in making the operation after the manner recommended by Reginald Harrison He would not advise the cutting of the prostate gland You may go beyond your legal rights He had recently used the urethral bougie, 23 American, scale 46 French He had no urethral fever to follow it

DR LEWIS BAUER said the question involved is, are there impermeable urethral strictures or not? He thought these strictures permeable When you have impermeable stricture you cannot introduce the instrument If you cannot evacuate the bladder and cannot go in through the penis, you must perform external urethrotomy He does not use chloroform, but puts the patient in the position for lithotomy, orders him to press down as if he were going to pass water, and with one quick thrust of the knife opens the urethra and the water gushes out He did not believe with Peterson that the bladder distends more upwardly than downwardly, but believes that it distends equally in every direction He thought internal urethrotomy could be performed easily and readily, and ought to be done more readily than it is There is liability to return if a fibrous stricture has been dilated by sounds He explained an instrument of his own which could be made to cut in any direction, thus opening up the different parts of the stricture He dwelt upon the necessity of disciplining the patient in the use of the catheter properly, for the urine must not pass over the wound

DR A M OWEN, of Evansville, arose to settle the point Is there, or is there not, impermeable stricture? He knows there is He had a patient who did not pass a drop of urine for ten years per urethra He met with a mechanical injury which left a cicatrix which closed the urethra *He found* ten or fifteen urinary fistulæ through the scroti He gave the particulars of the case, and explained minutely his treatment, which was successful

Dr Arch Dixon, of Henderson, Ky , related

A CASE OF GONORRHŒAL STRICTURE WHERE THE URETHRA WAS GROWN TOGETHER

Dr Joseph Eastman, of Indianapolis, said The paper urges the importance of a thorough knowledge of the perineum This is right, notwithstanding that Dr Bauer speaks lightly of this, and thinks that a distended urethra cannot be missed When we cut into the bladder of a female we relieve her of a suffering from cystitis worse than death Why should we not do so in the male? He thought there was here a field for study and improvement, and urged on those present to consider the matter carefully

Dr A C Bernays, of St Louis, said he thought the question whether or not impermeable stricture existed, was settled We have had two cases, one cicatricial, one gonorrhœal He considered the three operations, thought all were useful, but favored Cox's, or the English operation

Dr Sutcliffe, in closing the discussion, thought that tapping in front of the prostate gland, known as Gunther's operation, was excellent

Dr George Brinton Walker, of Evansville, Ind , read a paper on

PUERPERAL FEVER AND PUERPERAL SEPTICÆMIA

The word comes from *puer*, a child, and *parere*, to bring forth Although modern writers prefer another name in describing this condition, it is probable that the simple title, puerperal fever, will not soon be entirely abandoned The disease was recognized in the earliest antiquities Rachel, the beloved wife of the patriarch Jacob, as well as the wife of Phineas, is supposed to have died of this disease It was mentioned by Hippocrates, the discerning father of medicine First called puerperal fever by Dr Strother, in 1716 It is divided into sporadic and epidemic, or inflammatory and congestive Also divided into synochal, sthenic, or benign or typhoid, as thenic, putrid, or malignant In fatal cases patient dies three to ten days after confinement From eminent authorities we may consider puerperal fever to be an inflammatory disease, some sthenic, some asthenic It generally involves the peritoneum occasionally the appendages of the uterus and uterine veins and lymphatics The mode of reception of the poison is divided into auto and hetero infection Here the doctor quoted largely from Thomas's recent paper before the New York Academy of Medicine, and the discussion which followed He cited the conflicting testimony of both modern and ancient authors From an impartial consideration of all authors and his own experience the doctor was lead to the following statements

1 That the fever which attacks woman in the puerperal state may consist of numerous and distinct pathological conditions It may be a sthenic disease caused by injury or shock from the passage of the child through the genital tract

2 It may be asthenic, or malignant, from some occult cause associated with the traumaticism of labor

3 It may be the result of toxæmia from septic matters entering into and circulating through the vascular system

As to the agency of bacteria, he thought the subject may be regarded as undecided, and inviting further investigation Dr Byford thinks several diseases are included under the denomination of puerperal fever, especially as distinguished by the profession at large There are metritis and metro peritonitis without septic infection In the septicæmic variety treatment consists in relieving, 1st Inflammatory condition, 2d High temperature, 3d Malignant results of septicæmia, 4th Insufficient strength, tone up and stimulate the patient

In the purely inflammatory form the antiphlogistic treatment is indispensable In the malignant variety, opiates, stimulants, stupes externally, and calomel, quinine in 10, 20, 30, 60 grain doses, should be given The doctor, the nurse, and others about the patient should be clean, especially the patient herself He did not think ante-partal antiseptic injections advisable They are not only unnecessary, but really hurtful, by subjecting patient to a painful system of annoyance, which of itself may cause disease It is worse than meddlesome midwifery, because it anticipates labor and does not permit the woman to enjoy necessary rest when labor is completed

Dr S E Munford, of Princeton, Ind , recalled one case which resulted in death He had, the day previously, attended a case of erysipelas He has no doubt that physicians do carry this disease In treatment, the two great remedies are opium and quinine in large doses in the malignant cases

Dr Eastman, of Indianapolis, would insist that obstetric cases must be treated as others He wants to be put on record as saying that a woman should not necessarily lie in bed nine days, but must sit up every day to allow her bed to be thoroughly renovated, and to allow the clots to pass more thoroughly We cannot consider puerperal fever aside from surgical septicæmia He doubts if a woman was ever delivered of a child where an abrasion did not occur, in comparison with which the puncture for vaccination is small An old Irish woman had taught him a lesson by ordering the patient to get up and pass the clot in the chamber Simon recommended giving women more liberty after laceration of the cervix He was opposed to carbolic acid and in favor of the bichloride This latter he dissolved in glycerine, then diluted to 1 400 Ice or warm applications applied to the parts are both beneficial and both act in about the same way He has much faith in quinine and the salycilate of soda More faith in the prevention with the bichloride, and most in perfect cleansing of the bed every day

Dr Louis Bauer discussed auto infection He thinks prevention of infection to be a question of cleanliness, not one of time He thinks he has put it to the test in one of his cases He used his hands freely in a case of phlegmonous erysipelas, and did an ovariotomy the next day He took his accustomed bath, washed his hands, using a solution of ammonia, and changed his clothes He thinks the bichloride is generally accepted as the safest antiseptic, yet we find with it painful tenesmus straining, and death He thinks 1 400 too much, 1 10,000 has been found by experiment to kill bacteria Such a deadly poison certainly should not be used any more concentrated than necessary

Dr Arch Dixon, of Henderson, Ky, thought with Dr Eastman that puerperal septicæmia could not be separated from surgical septicæmia He allows his patients to get up and to pass the clots out into a chamber the second day It might be better to allow them to do so sooner He uses carbolic acid or bichloride solution, and recommends scrupulous cleanliness He believes that all cases come from the absorption of infectious matter

Dr E S McKee, of Cincinnati, thought it safe to use a post partal antiseptic vaginal injection He had been so trained in the clinic of Karl Braun, in Vienna, and had never omitted it since but that he regretted so doing Referred to a fatal case of puerperal septicæmia which he reported in the *Louisville Medical News*, Sept 5th, 1885 Preferred the bichloride to the carbolic acid

Dr James H Letcher, of Henderson, favored the greatest possible cleanliness He is not so much in favor of the routine vaginal injection as he was earlier in life The clots, he thinks, pass perfectly well in the reclining position

Dr Walker closed the discussion, saying the object of the paper had been to lay the present state of the subject before the Society and elicit discussion He had not such great confidence in large doses of quinine as some practitioners

(*To be concluded*)

OBSTETRICAL SOCIETY OF PHILADELPHIA

(*Concluded from page 333*)

Stated Meeting, Thursday, September 3d, 1885

Dr Goodell exhibited his improved uterine dilator He said that the main difficulty in the operation for the rapid dilatation of the cervical canal, lay in the liability of the blades of the instrument to slip out This he had in a great measure overcome by having shallow grooves cut into them Into these grooves the tissues sank, and the resulting friction kept the instrument in place Since he had called the attention of the Society to his instrument, not quite a year ago, he had performed the operation forty-one times for dysmenorrhœa and sterility, making in all 209 such cases In not a single instance had dangerous symptoms followed, and the average of success was a very large one He had become firmly convinced that for dysmenorrhœa and sterility the operation of rapid dilatation of the cervical canal would, except in some very rare cases of stenosis of the os externum, wholly supersede the cutting operation, the use of tents, or the slow dilatation by any means whatever, for by the former not only was the measure of success far greater, but the danger from inflammation was very much less He dilated the parts from three quarters of an inch to one inch and a quarter as measured off by the register in the handles, watching the cervix carefully to see what strain it could bear His instrument could be opened to the width of one and one half inches, but he resorted to that extreme divergence only when wishing to introduce his finger for diagnostic purposes This he could not ordinarily do unless the parts were relaxed from hæmorrhage Usually, however, when suspecting the existence of a polypus, he did not fine it needful to pass in his finger, for after a moderate dilatation he introduced a fenestrated forceps and opened it at hap hazard In this manner he has repeatedly caught and twisted off a polypus without knowing it was present, the subsequent removal of the growth through the os uteri being the most difficult part of the operation

Dr Baer was strongly impressed by the case of a lady whom he had delivered to day, as to the advisability of entirely giving up division of the cervix A year and a half ago he had slit up the cervix posteriorly, and to day he felt very anxious during the first stage of labor as to the probability of laceration of the uterus, starting from the seat of the former operation The anterior lip was very long coming down under the pubis and the posterior lip could not be felt When the uterus contains a polypus, the continued hæmorrhages reduce the contractility, and a single dilatation will sometimes enlarge the os sufficiently to admit the finger or forceps, but, if the uterus is healthy, it contracts immediately after the withdrawal of the dilator He could not recall an instance of inflammation following rapid dilatation Sterility of long standing is seldom cured by dilatation or any other means

Dr C M Wilson had seen recently, in the practice of Dr Ellwood Wilson, a uterus the cervix of which had been divided bilaterally some years ago The operation had resulted in the development of the symptoms peculiar to a bad laceration of the cervix, with ectropion Trachelorrhaphy was performed by Dr Agnew, with complete relief to the patient Dr Wilson mentioned this case to call attention to the change in opinion and practice since Emmett proposed the operation

Dr Longaker inquired as to the prevention of slipping of the dilator, and called attention to the original method of pressure over the fundus of the uterus

Dr J G Allen has performed rapid dilatation over seventy five times, and has never seen any bad results from the operation The blades of his instrument diverge as they separate, and there is no disposition to slip out The blades are more curved than in Dr. Goodell's instrument, he thinks that an advantage in holding the instrument in place, the handles are turned up so as not to touch the bed or table.

Dr. Goodell prefers the slight curve, so that in flexion of the uterus he can introduce the dilator with its curve reversed to the bend in the womb, and by opening the dilator in that position rectify the flexion of the organ. He prefers parallelism of the blades because the stenosis of the cervix is greatest at the external os, and there is no need for dilatation above the internal os. He considers it dangerous to press the fundus of the uterus down while using the dilator, for fear of wounding or even penetrating the tissues, and he uses a strong tenaculum to hold the organ, but since he had got Mr. Gemrig to roughen the blades by grooves, he had not been annoyed by the slipping of the instrument. He rarely finds it necessary to separate the blades more than one inch, but he sometimes does so to the extent of one and a half inches, especially when he wishes to introduce his finger into the uterine cavity.

Dr. Goodell exhibited two specimens of

PAROVARIAN CYSTS.

In each case the cyst was so detached from the ovary, that the former could have been taken away without injury to the ovary. He was greatly tempted to practice conservative surgery in these cases, and leave the ovaries untouched, but on account of apparently incipient cystic degeneration, they also were included in the ligature and removed. Both these cases were operated on in his private hospital, and both had recovered. In his experience, the removal of parovarian or of broad ligament cysts was one of the most successful of operations. Out of a large number which he had performed he could recall but a single fatal case, and in that the result seemed hardly due to the operation. The lady lived in a distant city, and he did not see her after the operation, which was a very easy one. At the end of a week the bowels were moved, the stitches removed, and everything gave promise of an unusually prompt convalescence. On the twelfth day, however, she was seized with uncontrollable vomiting, and she died on the seventeenth day. Six months previously, she had had an attack of vomiting from which she barely escaped with her life. Thus far this year he had had eighteen ovariotomies, and this was the only fatal case among them.

Dr. Montgomery wished to ascertain the opinion of the Society as to the advisability of removing the second ovary when, in an operation for the removal of an ovarian cyst, the other ovary was found to be slightly diseased. In his first ovariotomy, performed in 1879, the second ovary was found to contain numerous small cysts, it was not removed, and the patient has since been twice pregnant, and there has been no appearance of another tumor, nor any symptoms referable to the remaining ovary. If the climacteric has been passed there would be no question about it.

Dr. Baer inquired if tapping ever cured parovarian cysts? It was formerly reported as a means of cure. Do they always return after tapping? Would Dr. Goodell recommend tapping in an undoubted parovarian cyst? He, himself, felt strongly inclined toward abdominal section in all cases. He thinks the second ovary should be removed when it is not healthy, as the idea of a second operation is very depressing to a patient.

Dr. Montgomery knew of one instance of parovarian cyst which had been tapped and had refilled seven times. It was finally removed by him by peeling out the cyst, as on opening the abdomen he found the tumor universally adherent. Only one ligature was required, viz., on the stump of an enlarged ovary which bulged prominently into the cyst cavity.

Dr. J. G. Allen considered that, as an ovary somewhat diseased may give rise to a pregnancy, it should be left. We knew too little about the probability of the development of such small cysts into large ones. Until we have certain data on the subject, it must be considered a case of want of information and knowledge.

Dr. Parish was in accord with Dr. Allen as to the want of knowledge. He has seen diseased ovaries containing numerous small cysts in many autopsies, and there had been no symptoms during life to excite a suspicion of their existence. The existence of minute cysts cannot be considered as proving any liability to the production of large ones. If the second ovary contained a cyst as large as a partridge's egg, he would remove it, but if numerous cysts as small as a split pea were present, he would not. The possibility of conception should be considered as well as that of a cyst.

Dr. Goodell acknowledged the truth of the points made by Drs. Allen and Parish, and he believed that he had repeatedly removed the second ovary unnecessarily. Yet the history of his own ovariotomies shows a return of the disease in the remaining ovary in about two per cent., and he thought he erred on the safe and right side. The social conditions of the patient would always have a great weight with him. If an heir were wanted, or the patient were young, he would leave a suspicious-looking ovary, or try to remove the diseased portion of it. But in the majority of his cases, where there was any doubt, he removed the ovary. Of course, under such a rule, he must remove ovaries which might never give any trouble in the future. But the mental agony of women when informed that the operation must be performed a second time upon them, and, on the other hand, the great joy and satisfaction of patients when assured, after the close of an operation, that both ovaries had been removed, have determined him that, other things being equal, it is better to remove the second ovary. As to the cure of parovarian cysts by tapping, his own experience is not sufficient yet to decide absolutely. He would advise the radical operation, but if the patient, after understanding the liability of return, wishes it, he would tap, as there was but little danger from tapping such cysts. A patient was tapped by Dr. Atlee, some twenty years ago, five years afterwards the cyst filled and was tapped by Dr. Goodell. It then partly refilled, and so remained for a long while, the fluid then was gradually absorbed and never returned. He has had, beside and the salycilate of soda. More faith in the prevention with the bichloride, and most in perfect cleansing of the bed every day.

Dr. Louis Bauer discussed auto infection. He thinks prevention of infection to be a question of cleanliness, not one of time. He thinks he has put it to the test in one of his cases. He used his hands freely in a case of phlegmonous erysipelas, and did an ovariotomy the next day. He took his accustomed bath, washed his hands, using a solution of ammonia, and changed his clothes. He thinks the bichloride is generally accepted as the safest antiseptic, yet we find with it painful tenesmus, straining, and death. He thinks 1:400 too much, 1:10,000 has been found by experiment to kill bacteria. Such a deadly poison certainly should not be used any more concentrated than necessary.

Dr. Arch. Dixon, of Henderson, Ky., thought with Dr. Eastman that puerperal septicæmia could not be separated from surgical septicæmia. He allows his patients to get up and to pass the clots out into a chamber the second day. It might be better to allow them to do so sooner. He uses carbolic acid or bichloride solution, and recommends scrupulous cleanliness. He believes that all cases come from the absorption of infectious matter.

Dr. E. S. McKee, of Cincinnati, thought it safe to use a post partal antiseptic vaginal injection. He had been so trained in the clinic of Karl Braun, in Vienna, and had never omitted it since, but that he regretted so doing. Referred to a fatal case of puerperal septicæmia which he reported in the *Louisville Medical News*, Sept. 5th, 1885. Preferred the bichloride to the carbolic acid.

Dr. James H. Letcher, of Henderson, favored the greatest possible cleanliness. He is not so much in favor of the routine vaginal injection as he was earlier in life. The clots, he thinks, pass perfectly well in the reclining position.

Dr. Walker closed the discussion, saying the object of the paper had been to lay the present state of the subject before the Society and elicit discussion. He had not such great confidence in large doses of quinine as some practitioners.

(*To be concluded.*)

OBSTETRICAL SOCIETY OF PHILADELPHIA.

(*Concluded from page 333.*)

Stated Meeting, Thursday, September 3d, 1885.

Dr. Goodell exhibited his improved uterine dilator. He said that the main difficulty in the operation for the rapid dilatation of the cervical canal, lay in the liability of the blades of the instrument to slip out. This he had in a great measure overcome by having shallow grooves cut into them. Into these grooves the tissues sank, and the resulting friction kept the instrument in place. Since he had called the attention of the Society to his instrument, not quite a year ago, he had performed the operation forty-one times for dysmenorrhœa and sterility, making in all 209 such cases. In not a single instance had dangerous symptoms followed, and the average of success was a very large one. He had become firmly convinced that for dysmenorrhœa and sterility the operation of rapid dilatation of the cervical canal would, except in some very rare cases of stenosis of the os externum, wholly supersede the cutting operation, the use of tents, or the slow dilatation by any means whatever; for by the former not only was the measure of success far greater, but the danger from inflammation was very much less. He dilated the parts from three quarters of an inch to one inch and a quarter as measured off by the register in the handles, watching the cervix carefully to see what strain it could bear. His instrument could be opened to the width of one and one half inches, but he resorted to that extreme divergence only when wishing to introduce his finger for diagnostic purposes. This he could not ordinarily do unless the parts were relaxed from hæmorrhage. Usually, however, when suspecting the existence of a polypus, he did not fine it needful to pass in his finger, for after a moderate dilatation he introduced a fenestrated forceps and opened it at hap-hazard. In this manner he has repeatedly caught and twisted off a polypus without knowing it was present, the subsequent removal of the growth through the os uteri being the most difficult part of the operation.

Dr. Baer was strongly impressed by the case of a lady whom he had delivered to-day, as to the advisability of entirely giving up division of the cervix. A year and a half ago he had slit up the cervix posteriorly, and to-day he felt very anxious during the first stage of labor as to the probability of laceration of the uterus, starting from the seat of the former operation. The anterior lip was very long, coming down under the pubis, and the posterior lip could not be felt. When the uterus contains a polypus, the continued hæmorrhages reduce the contractility, and a single dilatation will sometimes enlarge the os sufficiently to admit the finger or forceps; but, if the uterus is healthy, it contracts immediately after the withdrawal of the dilator. He could not recall an instance of inflammation following rapid dilatation. Sterility of long standing is seldom cured by dilatation or any other means.

Dr. C. M. Wilson had seen recently in the practice of Dr. Ellwood Wilson, a uterus, the cervix of which had been divided bilaterally some years ago. The operation had resulted in the development of the symptoms peculiar to a bad laceration of the cervix, with ectropion. Trachelorrhaphy was performed by Dr. Agnew, with complete relief to the patient. Dr. Wilson mentioned this case to call attention to the change in opinion and practice since Emmett proposed the operation.

Dr. Longaker inquired as to the prevention of slipping of the dilator, and called attention to the original method of pressure over the fundus of the uterus.

Dr. J. G. Allen has performed rapid dilatation over seventy five times, and has never seen any bad results from the operation. The blades of his instrument diverge as they separate, and there is no disposition to slip out. The blades are more curved than in Dr. Goodell's instrument, he thinks that an advantage in holding the instrument in place, the handles are turned up so as not to touch the bed or table.

Dr. Goodell prefers the slight curve, so that in flexion of the uterus he can introduce the dilator with its curve reversed to the bend in the womb, and by opening the dilator in that position rectify the flexion of the organ. He prefers parallelism of the blades because the stenosis of the cervix is greatest at the external os, and there is no need for dilatation above the internal os. He considers it dangerous to press the fundus of the uterus down while using the dilator, for fear of wounding or even penetrating the tissues, and he uses a strong tenaculum to hold the organ, but since he had got Mr. Gemrig to roughen the blades by grooves, he had not been annoyed by the slipping of the instrument. He rarely finds it necessary to separate the blades more than one inch, but he sometimes does so to the extent of one and a half inches, especially when he wishes to introduce his finger into the uterine cavity.

Dr. Goodell exhibited two specimens of

PAROVARIAN CYSTS.

In each case the cyst was so detached from the ovary, that the former could have been taken away without injury to the ovary. He was greatly tempted to practice conservative surgery in these cases, and leave the ovaries untouched, but on account of apparently incipient cystic degeneration, they also were included in the ligature and removed. Both these cases were operated on in his private hospital, and both had recovered. In his experience, the removal of parovarian or of broad ligament cysts was one of the most successful of operations. Out of a large number which he had performed he could recall but a single fatal case, and in that the result seemed hardly due to the operation. The lady lived in a distant city, and he did not see her after the operation, which was a very easy one. At the end of a week the bowels were moved, the stitches removed, and everything gave promise of an unusually prompt convalescence. On the twelfth day, however, she was seized with uncontrollable vomiting, and she died on the seventeenth day. Six months previously, she had had an attack of vomiting from which she barely escaped with her life. Thus far this year he had had eighteen ovariotomies, and this was the only fatal case among them.

Dr. Montgomery wished to ascertain the opinion of the Society as to the advisability of removing the second ovary when, in an operation for the removal of an ovarian cyst, the other ovary was found to be slightly diseased. In his first ovariotomy, performed in 1879, the second ovary was found to contain numerous small cysts; it was not removed, and the patient has since been twice pregnant, and there has been no appearance of another tumor, nor any symptoms referable to the remaining ovary. If the climacteric has been passed there would be no question about it.

Dr. Baer inquired if tapping ever cured parovarian cysts? It was formerly reported as a means of cure. Do they always return after tapping? Would Dr. Goodell recommend tapping in an undoubted parovarian cyst? He, himself, felt strongly inclined toward abdominal section in all cases. He thinks the second ovary should be removed when it is not healthy, as the idea of a second operation is very depressing to a patient.

Dr. Montgomery knew of one instance of parovarian cyst which had been tapped and had refilled seven times. It was finally removed by him by peeling out the cyst, as on opening the abdomen he found the tumor universally adherent. Only one ligature was required, viz., on the stump of an enlarged ovary which bulged prominently into the cyst cavity.

Dr. J. G. Allen considered that, as an ovary somewhat diseased may give rise to a pregnancy, it should be left. We knew too little about the probability of the development of such small cysts into large ones. Until we have certain data on the subject, it must be considered a case of want of information and knowledge.

Dr. Parish was in accord with Dr. Allen as to the want of knowledge. He has seen diseased ovaries containing numerous small cysts in many autopsies, and there had been no symptoms during life to excite a suspicion of their existence. The existence of minute cysts cannot be considered as proving any liability to the production of large ones. If the second ovary contained a cyst as large as a partridge's egg, he would remove it, but if numerous cysts as small as a split pea were present, he would not. The possibility of conception should be considered as well as that of a cyst.

Dr. Goodell acknowledged the truth of the points made by Drs. Allen and Parish and he believed that he had repeatedly removed the second ovary unnecessarily. Yet the history of his own ovariotomies shows a return of the disease in the remaining ovary in about two per cent., and he thought he erred on the safe and right side. The social conditions of the patient would always have a great weight with him. If an heir were wanted, or the patient were young, he would leave a suspicious-looking ovary, or try to remove the diseased portion of it. But in the majority of his cases, where there was any doubt, he removed the ovary. Of course, under such a rule, he must remove ovaries which might never give any trouble in the future. But the mental agony of women when informed that the operation must be performed a second time upon them, and, on the other hand, the great joy and satisfaction of patients when assured, after the close of an operation, that both ovaries had been removed, have determined him that, other things being equal, it is better to remove the second ovary. As to the cure of parovarian cysts by tapping, his own experience is not sufficient yet to decide absolutely. He would advise the radical operation, but if the patient, after understanding the liability of return, wishes it, he would tap, as there was but little danger from tapping such cysts. A patient was tapped by Dr. Atlee, some twenty years ago, five years afterwards the cyst filled and was tapped by Dr. Goodell. It then partly refilled, and so remained for a long while, the fluid then was gradually absorbed and never returned. He has had, beside this one, two cases which he tapped, one five years ago and the other three years ago, and there has been no return whatever of the fluid. On the other hand, he has had two or three cases in which the cyst burst spontaneously several times, and yet refilled invariably. The rupture was followed immediately by some collapse and pain, and later by an excessive secretion of urine, with complete subsidence of the tumor. He had also heard of several cases of rupture, but, as far as he has learned the history of such cases, the cyst has always returned. The reports of the cure of ovarian cysts by tapping and injection of tincture of iodine *must be true only* of parovarian cysts.

Dr. Harris knew of a case of parovarian cyst in which fourteen years had elapsed between the tapping and the subsequent refilling.

Dr. E. E. Montgomery read the following supplement to his paper on

BROMIDE OF ETHYL

I read a paper on bromide of ethyl as an anæsthetic in labor, before the April meeting of this Society. Although I did not attempt a history of the early administration of the drug, subsequent investigation has shown me that I did Dr. Turnbull injustice in not mentioning that to him we are indebted for the revival of this agent, and its first use in this country. In following the German literature, by which I was led to use this drug in labor, I ascribed its first obstetrical use to Lebert, of Paris. The first case in which he used it was for the application of forceps, and occurred in March, 1881, but a paper published by Dr. Turnbull (*Med. Bul.*, June, 1880) shows that he had then used it in a second case of labor, and spoke in high terms of its peculiar advantages. Dr. H. Augustus Wilson had used it in labor prior to August 7, 1880, when he published an article upon this drug (*Med. and Surg. Rep.*, Aug. 7, 1880). It becomes quite evident that the first obstetrical trial of this agent was made in this city, and the priority lies between the gentlemen named. Various mixtures of the ethyl have been advocated in labor and minor operations. Booth, of Ohio (*Ther. Gaz.*, 1884–5, p. 159) recommends alcohol two parts, chloroform and bromide of ethyl each one part. W. H. Byrd, Quincy, Ill. (*Ther. Gaz.*, March, 1884) has used bromide of ethyl one part, chloroform three parts, alcohol four parts, in some ninety eight cases, without a single unpleasant symptom. It has not everywhere received the same condemnation that is shown by the hesitancy to use it in this city. In spite of the bad name given it by two deaths under its use, and the apparently dangerous symptoms induced by experiments upon the lower animals, its use has been revived by Chisolm (*Maryland Med. Journal*, 1882–3) and Prince (*St. Louis Med. and Surg. Jour.*, 1883, XIV, 297), who strongly urges its use in minor operations and preliminary to the administration of ether. The last named has reported 500 cases in which it was used without a single unpleasant symptom. A leading article in the *Ther. Gaz.*, June, 1885, advocates a redistillation of a mixture of bromide of ethyl and olive oil as a valuable and safe anæsthetic in labor. These facts are referred to simply to induce the profession to give this anæsthetic a fair trial in ameliorating the terrible suffering of natural labor.

Dr. Montgomery exhibited a

UTERINE FIBROID POLYPUS

Miss R., æt. 38 years, began to menstruate at 17 years. The flow was regular, quite free, lasting a week, and was attended with pain the first three days. Ten years ago she had a hemorrhage, and subsequently several such attacks. Two years later she had a severe hemorrhage followed by a bloody discharge continuing several months, since which time she has never been regular. The flow would occur too frequently, be very profuse and attended with pain and loss of flesh. The symptoms were more marked during the last year. At one of the hospital clinics, some years ago, the difficulty was ascribed to anteversion of the womb. Dr. Bournonville examined her three weeks ago, diagnosticated the condition fibroid polypus, and referred the case to me for treatment. She was quite pale, lips bloodless, complained of pelvic pain and of a constant bloody discharge which amounted to hemorrhage upon the slightest exertion. The vagina was dilated by a tumor the size of an orange, about whose pedicle could be felt the neck of the uterus. The finger passed into the os and about the tumor without difficulty. Every examination was followed by severe hemorrhage. The pedicle was cut through by means of the wire ecraseur, and the tumor removed by means of a pair of polypus forceps. Considerable hemorrhage followed its removal. As this was not controlled by application of hot water, a tampon saturated with a solution of subsulphate of iron was introduced. This was removed on the second day. On the fourth her temperature ran up to 103°, she had a chill and pains in various parts of her body. These symptoms vanished under the use of quinine, digitalis and opium. Five weeks after the operation she appeared much improved, has had no bleeding since, her appetite and strength are greatly increased, the uterus was normal is size, the cervix still dilatable and will admit the finger with pressure; the cervical membrane was in good condition. The tumor was the size of an orange, mucous membrane of the lower surface was ulcerated so that vessels were ruptured, allowing hemorrhage on any exertion. The case is of interest from the long continuance of the hemorrhage, and illustrates the importance of early and careful examination of the cavity of the uterus in cases of protracted hemorrhage.

Dr. Goodell seldom uses the wire now for the removal of uterine polypi. He prefers traction with twisting or enucleation by the finger. There is less bleeding and he is afraid of "cupping" of the fundus uteri and its injury by being included in the wire loop. He had made traction with the obstetric forceps, and enucleated tumors so large as to rupture the perineum even after lateral incisions had been made in the labia. He partially inverted the womb, enucleated the tumor and thus restored the organ to its proper form. The tumor some times occludes the os, and fetid pus from necroses of the growth is imprisoned above it, giving rise to a suspicion of cancer.

Dr Baer thinks Monsel's solution may have caused the high temperature, vinegar would have been a better hemostatic, and it is also an antiseptic From the appearance of the specimen, a portion of the adventitious growth seems to have been left behind, and it would be interesting to know the history of the stump

Dr Parish has removed many fibroids of various sizes, and sometimes with degenerated tissues and noisome odors The rapid recovery of Dr Montgomery's patient was remarkable It is much to be regretted when any portion of the tumor is left, as necrotic change is rapid and decided in such tissue and there is danger of blood poisoning The pedicle, however, generally shrinks and disappears

Dr Goodell remarked that this tumor appeared to be sessile and had been wholly removed The pedicle proper is usually simply mucous membrane without adventitious tissue, and it makes very little difference if some of it is left behind, as it shrivels away and is absorbed

Dr Allen sometimes regretted that he was compelled to leave a portion of pedicle or tumor in the uterus, but he has never seen any bad consequences follow it He prefers vinegar to iron as a hæmostatic and considers it as good an antiseptic as carbolic acid

Dr Montgomery remarked that the wire evidently brought away all the tumor There was no evidence of any remnant on examination to day In one case a portion of tumor or pedicle was unavoidably left, and he removed it some time afterwards by means of a tenaculum He wounded his finger in doing so and suffered from septicæmia The woman had an attack of cellulitis

STATE MEDICINE

GOOD HEALTH IN MICHIGAN

Sanitarians have claimed that the observance of sanitary precautions would diminish sickness from many diseases, a lessening of sickness in the summer of 1885 was, accordingly, expected On studying the combined reports of sickness in Michigan in July, 1885, compared with the average for July in the seven years 1879–1885, it is found that sickness from all the more important diseases was in July, 1885, much less than the average A supplementary bulletin was issued giving a list of diseases, arranged in order of greatest diminution of prevalence From this, and from other information received at this office, it seems very probable that much of the great decrease in sickness was due to the increased sanitary precautions on account of the expected visitation of cholera

A study of the statistics now exhibits a similar decrease in sickness from nearly every disease in August, 1885, compared with the average of preceding Augusts, 1879–1885 From fevers and bowel complaints there is shown to be a very marked decrease This seems to confirm what was claimed in the supplementary bulletin for July It is proper to state, however, that although in July, 1885, the meteorological conditions were not very favorable, in August, 1885, they were favorable to health

Henry B Baker, Sec'y

Lansing, Mich , Sept 4, 1885

DOMESTIC CORRESPONDENCE

LETTER FROM NEW YORK

Resumption of Society Meetings—Proceedings of Society of Medical Jurisprudence and State Medicine—Commissioners of Charities, etc , etc

The Medical Society season was opened on the 17th, when the Society of Medical Jurisprudence and State Medicine held its first meeting after the summer vacation On this occasion Mr Charles F Wingate, one of the leading sanitary engineers of the city, read a paper on some of the sanitary problems of New York There was room for reform, he said, in the mode of living among the well-to do, as well as among the tenement house population One great trouble was that they are too economical of their space, for while many of the rich could easily afford room for a garden and some growing flowers, it was the almost invariable custom to take up nearly the entire lot with buildings, so that the houses were insufficiently lighted and ventilated Again, the homes of the wealthy are filled with elegant upholsteries and tapestries, and these, on account of their absorbent properties, are likely to be sources of the greatest possible danger in case of there being any bad plumbing or unwholesome cellars about the premises On account of the enormous manufacturing interests of the city, he continued, the growth of industrial disease was rapid here He then dwelt for some time on the sanitary defects of the public schools by reason of which the average of days lost from sickness by children in New York was rendered much too large, in comparison with the state of affairs in many other localities Unfortunately, there was too much apathy on the part of the authorities in regard to the subject Mr Wingate spoke very highly of the efficiency of the new plumbing law, the good results of which had been repeatedly observed by him The effect of it was, that bad plumbing was now found to be confined almost entirely to the old houses As to the requisites for improving the health of the city, he suggested, among other things, better drainage, and the building of one or two large main receiving sewers, the cremating of garbage, more water, repairing of the streets with something besides cobblestones, more public baths, and more small parks or breathing spaces in down-town districts It would be a good idea, he thought, to have one or two of the city piers terraced and transformed into promenades for the people

The Commissioners of Charities and Corrections, having been empowered by the Legislature to do so, have purchased 860 acres of land near Central Islip, Long Island, to be used as a farm for the insane, where many of those now inmates of the crowded city institutions on the islands in the East river can be employed in light occupations The tract of land purchased is forty-three miles from New York, and consists of wild land unimproved, but is well watered and timbered Such a farm for the insane has long been needed here, and it will, no doubt, prove a lasting benefit to the community

The Italian brig, La Regina, recently arrived at lower quarantine with yellow fever on board, three of the crew being affected with the disease at the time of the arrival of the vessel These were at once transferred to the hospital in the lower bay The captain informed Health Officer Smith that he sailed from Cayenne, August 1st, and that shortly after leaving port Captain Kerne, of Prospect, Me, an old shipmaster, who was a passenger, was taken with yellow fever He died August 4th, and was buried at sea, and before the voyage was ended the mate and three seamen also died of the disease and were buried at sea

Dr Cyrus Edson, chief of the Second Sanitary Division of the Board of Health, who has been doing an excellent work during the past summer in seizing large quantities of fruit and other articles that were unfit to eat, was gratified to find, on making a recent raid upon the Hebrew markets in the lower part of the city, the vendors in which had previously been peculiarly troublesome in their disregard of the law, that good vegetables, fruit and meat were on nearly all of the stalls The consequence was that he had only to confiscate some five hundred pounds of unwholesome food, instead of from three to six tons, as on former occasions

That some of our prominent medical men have an eye to the main chance must be acknowledged, if the following statement, reported by a writer in one of the daily papers, is correct "That man made a clear $25,000 last year," said a friend to me the other day pointing out a well known New York physician "I mean $25,000 above and clear of the big revenue that comes from his city practice How? Two years ago he established an inebriate asylum in a village fifty miles out of town, and fancy fees for treatment there are making him a fortune Though the general public does not know that he is in this kind of business, some of the richest families in this town are sending him checks" P B P

A CRITICISM

To THE EDITOR OF THE JOURNAL

Dear Sir —While I have no ambition to pose myself in journalistic notoriety, yet I occasionally see some things so ludicrous that I almost feel like taking up my well-worn goosequill and scratching off some of my mental effusions, even though it be with no better logic or sense of propriety than I occasionally see in some of the journals I take and read

I have now particular reference to the *Columbus Journal of Medicine*, edited by J F Baldwin, M D, in the September number of which he, in speaking about the International Medical Congress, uses the following language "The International Congress muddle is in a little worse shape than when we wrote a month ago, that is, many additional resignations have been sent in" But the wise, well posted editor fails to give the names of the *many* who have resigned in the last month, and then he goes on to say "The JOURNAL of the Association still keeps a stiff upper lip, *and swears it is not going to be much of a shower, and devotes its energy to abusing those who have resigned*" Now, I am a constant reader of the JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, and I would like for the wise editor of the *Columbus Journal* to point out where and when the venerable editor of the JOURNAL indulged in abuse, either personally or professionally, of those eminent gentlemen who have seen fit to resign their position on, or participation in the Committee of Arrangements But that is not all, in the same article the editor goes on to say "The JOURNAL (meaning the JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION) at one time held the key to the situation (and I think it does yet), it could have changed the entire aspect of affairs, if it had only chosen to act the peacemaker, but the *choleric* old gentleman who acts as editor has simply made himself an offensive partisan, whose rulings fall on heedless ears"

Now, if the editor of the *Columbus Journal* had said *headless* instead of *heedless*, he would have hit the nail square on the *ear*, less the head But, to be brief, the editor of the *Columbus Journal* reminds me, in his low flung vulgar attack upon the venerable and able editor of the JOURNAL, of a very small *fist* running out in the street and barking at a noble mastiff, or a very young chicken trying to crow before the pin feathers had begun to sprout Trusting that the youthful editor of the *Columbus Journal* will learn from this hint a slight sense of journalistic propriety, and some little sense of the propriety and respect due a member of the medical profession, and especially one whose age and brilliant service in the profession have won for him the enviable distinction of Nestor, among his professional brethren J M

Ironton, Ohio, Sept 18, 1885

EARLY AND SUCCESSFUL LAPAROTOMY OPERATION

To THE EDITOR OF THE JOURNAL

Dear Sir —The other day, in glancing over a file of old newspapers, the following paragraph was observed It is copied verbatim, and though meagre in details it furnishes conclusive evidence of an early and successful laparotomy operation, by William Baynham, of Virginia This gentleman was, in his day, one of the most accomplished anatomists and surgeons He was born in Caroline Co, Va, Dec 7, 1749, and died at his residence in Essex Co, Va, Dec 8, 1814 After studying with his father, Dr John Baynham, he went to England to further prosecute his studies He remained in London, connected with St Thomas's Hospital and as a practising surgeon, for sixteen years On his return to America, which he had left as colonies, they had, in his absence, become a Nation He settled to practise his profession in Essex, and to the close of his life had a large and responsible practice At the date of this operation there were no medical journals published in the United States He may have reported it to some of the medical societies to which he belonged in London, or later to journals published in America He did report a case or cases of extra uterine conception, and this case may be the one However, as all cases of this kind are of special interest to the surgeon and gynæcologist, I venture, at the risk of a duplication, to request you to give it a place in your widely read and influential journal

I

RICHMOND, [VA ,] Jan'y 26, 1791

On Saturday, the 14th inst , Mrs Locke, wife of Mr John Locke, of Caroline county [Va], was delivered of a dead child, which she had carried for upwards of ten years The child appeared to have been of the size of a full grown one of nine months old, and was extracted through an opening made in the side of its mother by Dr [William] Baynham We are happy to hear that Mrs Locke is as well as can be expected after so uncommon and painful an operation, which she is said to have borne with great fortitude —*The Georgia Gazette*, Thursday, March 10, 1791

PLACENTA PRÆVIA

On the morning of March 30, 1881, I was called in haste to see Mrs S A , primapara, aged 22 years When I entered the room the nurse informed me that the patient had had some slight pains during the night, but thought it not necessary to send for me until daylight, but that about twenty minutes previously she felt a gush of blood, and, as she said, was then flowing "horridly" Sitting on the side of the bed I made an examination, and found the os uteri dilated nearly the size of a silver dollar, with the placenta lying across the opening and adherent

Labor pains were slow, having occurred but twice since she began to flow Forcibly passing the index finger between the placenta and cervix, I found a vertex presentation, third position Assuring the patient, who was already badly scared, that she was in no danger, but that it was best, for the safety of the babe, to apply forceps and deliver at once, I ruptured the membranes, and told the husband to give her one teaspoonful of Squibb's fluid extract of ergot with two of brandy Without waiting to change the position of the patient across the bed, I applied the forceps, and began slight traction, when strong contraction of the uterus took place I increased the traction on the forceps with the right hand, and with the left on the fundus of the uterus made gentle but steady pressure downwards As soon as the head began pressing upon the perineum I changed my hand from the abdomen and supported the perineum

Fifteen minutes from my first entrance into the room a large male child was born, to all appearances dead As I had previously ordered the nurse to bring me a dish pan of warm soft water, I placed the child into it once, and began artificial respiration I was rewarded in five minutes by its showing signs of life, and in seven minutes by hearing it cry lustily Turning my attention to the mother, I found a very slight tear in the perineum The placenta came down with and around the neck of the child

The method of procedure in this case might be called "meddlesome midwifery," but I think the end justified the means Mother and child progressed nicely, and I have since attended her in confinement, using the forceps as labor was somewhat tedious, and as she wished to be delivered as quickly as before

This note has been called out by reading the report of an interesting case of Dr H V Sweringen, of Fort Wayne, Ind , on "Placenta Prævia," published in the JOURNAL of August 29

B M J CONKLIN, M D

Alexandria, Dak , Sept 8, 1885

BOOK REVIEWS

ANATOMY, PHYSIOLOGY, AND HYGIENE A Manual for the Use of Colleges, Schools, and General Readers By JEROME WALKER, M D, Lecturer upon Anatomy, Physiology and Hygiene at the Central School, Brooklyn, and upon Diseases of Children at the Long Island College Hospital, etc , etc With Illustrations New York A Lovell & Co , 1885

In order to give an idea of the scope of this book, and the careful manner in which it has been prepared, we cannot do better than give the following extract from the author's preface

"The kind of type and paper were selected under the advice of the well known physician and oculist, Dr C R Agnew, of New York Dr L C Gray, Professor of Mental and Nervous Diseases in the New York Polyclinic Medical School, and Dr J C Shaw, Superintendent of the King's County Insane Asylum, have carefully reviewed the manuscript and proof of the chapters on the Nervous System In like manner, Dr A Mathewson, Ophthalmic Surgeon to St John's Hospital, and the Brooklyn Eye and Ear Hospital, has reviewed the chapters on Sight and Hearing Dr E H Bartley, Analytical Chemist to the Department of Health of the City of Brooklyn, and Lecturer on Chemistry at the Long Island College Hospital, has examined that portion of chapter X which relates to Water, Dr T R French, Consulting Laryngoscopic Surgeon to St Mary's Hospital, etc , and Dr S Sherwell, Physician to the Throat Department of the Brooklyn Eye and Ear Hospital, have reviewed the manuscript and proof of the chapter on Voice, and Dr J H H Burge, Surgeon to the Long Island Hospital, has reviewed the manuscript and proof of the chapter on Emergencies "

The interest of the reader begins at the very preface of this book, and does not flag until the final page is finished For the purposes for which it is written it is the most interesting and the fairest exponent of present physiological and hygienic knowledge that has ever appeared It should be used in every school, and should be a member of every family —more especially of those in which there are young people It is a pleasure to read and review such an excellent book

ASSOCIATION ITEMS

MEMBERSHIP BY APPLICATION

At the meeting of the American Medical Association held at Washington, in May, 1884, an amendment to Regulation II was adopted, which provides that membership in the Association shall be obtainable by any member of a State or County Medical Society recognized by the Association, upon application endorsed by the President and Secretary of said Society, and shall be retained so long as he shall remain in good standing in his local Society, and shall pay his annual dues to the Association Hitherto attendance as a delegate at an annual meeting has been necessary in order to obtain such membership

Application for membership, accompanied with FIVE DOLLARS, for annual dues, and the Certificate of Membership in the local Society, should be sent directly to the undersigned, on receipt of which the weekly JOURNAL OF THE ASSOCIATION will be forwarded for one year

RICHARD J DUNGLISON, M D , *Treasurer*
Lock Box 1274, Philadelphia, Pa

MISCELLANEOUS

RESIGNATION —We are informed that Prof J J M Angear, of this city, Professor of Principles of Medicine in the College of Physicians and Surgeons of Chicago, has resigned his position in that institution

THE ILLINOIS STATE BOARD OF HEALTH —The State Board of Health for Illinois sends us a number of documents regarding its work, which show that the Board is earnestly and energetically striving to instil into the minds of every one that it can reach a knowledge of the principles and practice of public hygiene Its last quarterly report contains a gratifying account of progress in this direction The most important effort of the Board at the present time is the compilation of a State Sanitary Survey, forms for which have recently been compiled, and sent all over the State The schedule to be filled up appears to contain everything that is requisite for a complete knowledge of the sanitary circumstances of each house, and thus of each district, and we can well understand that the facts which the survey has revealed are stirring up the local authorities to greater sanitary activity We wish the Illinois Board of Health all success in its praiseworthy efforts to fulfil the objects of its creation —*Brit Med Jour* , Aug 8, 1885

AMERICAN RHINOLOGICAL ASSOCIATION —The following are the subjects of some of the papers (with the authors' names and addresses) to be read at the 3rd meeting of the American Rhinological Association to be held at Lexington, Ky , Oct 6th, 1885

Address to the Association on Rhinology, by the President P W Logan, M D , of Knoxville, Tenn

Chronic Otitis Media, its Treatment in Connection with Nasal Disease By Hiram Christopher, M D , of St Joseph, Mo

Self-Deception By the same author

Hypertrophic Rhinitis, its Sequelae and Treatment By J A Stucky, M D , of Lexington, Ky

Treatment of Catarrh, Acute and Chronic By A DeVilbiss, M D , of Toledo, Ohio

Treatment of Neoplasms of the Naso-pharyngeal Cavity A New Snare By J G Carpenter, M D , of Stanford, Ky

Aural Catarrh and Treatment by Different Methods with the Theory of each System By Chas A S Sims, M D , of St Joseph, Mo

Chronic Conjunctivitis Dependent upon Intra Nasal Disease By N R Gordon, M D , of Springfield, Ill

Demonstrations (on the Cadaver) of the Nasal and Pharyngo-nasal Cavities, the Pharynx and Larynx The Sections of the Cadaver will show all the Cavities, Canals and Sinuses connected with the Nasal and Pharyngo Nasal Cavities By Thos F Rumbold, M D , of St Louis, Mo

Demonstrations of the Manner of Making Applications by means of the Spray Producers, the age of the Patients being Respectively 1, 3, 8, 15 and 20 years and older By the same author

Removal of Foreign Bodies and Tumors from the Upper Air Passages, with Demonstrations on a Phantom Head By the same author

Treatment of Pruritic Rhinitis (Hay Fever), by Spray Producers alone, Cases By the same author

On the Treatment of Secondary and Tertiary Syphilis of the Larynx, Pharynx and Mouth By Jos B Payne, M D , of Hot Springs, Ark

A few Suggestions on Hypertrophy of the Turbinated Processes By E F Henderson, M D , of Los Angelos, Cal

Seven other papers are promised, but the subjects have not yet been given to the Secretary

The full Programme will be ready to mail to any address on and after the 23rd of Sept , on application to any of the above members, or to

CHAS A S SIMS, M D , Sec'y,
St Joseph Mo

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT U S ARMY FROM SEPTEMBER 12 1885 TO SEPTEMBER 18 1885

Col John Campbell Surgeon, retired from active service, Sept 16, 1885 (S O 212, A G O , Sept 16, 1885)

OFFICIAL LIST OF CHANGES IN THE MEDICAL CORPS OF THE U S NAVY DURING THE WEEK ENDING SEPTEMBER 10 1885

Murray, J M , Passed Asst Surgeon, resignation accepted, to take effect Jan 1, 1886

Ross, J W , Surgeon, to special duty at New York

OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF MEDICAL OFFICERS OF THE U S MARINE HOSPITAL SERVICE FOR THE FOUR WEEKS ENDED SEPTEMBER 19 1885

Vansant, John, Surgeon, to proceed to New Orleans, La , Sept 16, 1885

Hutton, W H H , Surgeon, when relieved, to proceed to Mobile, Ala Sept 16, 1885

Long, W H , Surgeon, granted leave of absence for ten days, Sept 1 1885 When relieved, to proceed to Detroit, Mich Sept 19, 1885

Fessenden, C S D , Surgeon to proceed to Norfolk, Va Sept 16, 1885

Sawtelle, H W , Surgeon, when relieved, to proceed to San Francisco, Cal Sept 18, 1885

Godfrey, John, Surgeon, when relieved, to proceed to Louisville, Ky , Sept 16 1885

Goldsborough, C B Passed Asst Surgeon, when relieved, to proceed to St Louis, Mo

THE SURGICAL TREATMENT OF CYSTS OF THE PANCREAS[1]

BY N SENN, M D,

OF MILWAUKEE WIS SURGEON TO THE MILWAUKEE HOSPITAL AND PROFESSOR OF PRINCIPLES AND PRACTICE OF SURGERY IN THE COLLEGE OF PHYSICIANS AND SURGEONS CHICAGO ILL

(*Concluded*[2])

Under the benign influence of aseptic surgery the domain of operative treatment of disease has been gradually but steadily expanding, so that, even at the present time, almost every organ of the body is within reach of surgical aid when it has become the seat of injury or disease The sphere of the physician is constantly being narrowed by successive achievements of modern surgery, which have been and are still multiplying with wonderful rapidity The useless and often pernicious administration of drugs for the cure of local affections must and will yield to rational local treatment Aseptic surgery has created a new era in the diagnosis of disease All the large cavities can now be opened and the organs examined with comparative immunity In obscure cases, speculative diagnosis must give way to direct inspection and palpation

Aseptic surgery has also revolutionized that most important branch of medical science—experimental physiology and pathology The realization of the object of our experiment is no longer marred or entirely frustrated by septic inflammation Recent experimental research has established many new facts in physiology and has laid the foundation for modern pathology Organs and parts of organs which were heretofore regarded as essential to the proper performance of the functions of life have been successfully removed in animals without producing any immediate or remote effects, and the knowledge thus obtained has been applied in practice, with the result of establishing, upon legitimate grounds, a number of the most brilliant and life-saving operations The surgery of the brain, the lungs, the heart, the liver, the kidneys, the gastro intestinal canal, is only in its infancy, and yet it has contributed largely towards relieving suffering and prolonging life, and at the same time, it has added lustre both to the science and the art of surgery Abdominal surgery is equivalent to aseptic surgery, and as such it is regarded favorably by many in the light of a new specialty Modern surgery has not only added precision to the diagnosis of obscure abdominal affections, but in many instances offers the only inducement for successful treatment Surgical affections of the kidney, spleen, stomach, intestines, and the essential organs of procreation in the female, have for some time constituted a fertile soil for surgical labor, with a certain promise for a rich harvest in the future

Of all abdominal organs, the pancreas has been least frequently subjected to surgical treatment The anatomical location of the organ, and the obscurity of its affections, furnish a sufficiently satisfactory explanation for this statement Situated high up in the abdominal cavity, and hidden behind such important organs as the stomach, omentum, and transverse colon, it is the least accessible of all abdominal organs, and on this account, its affections, wrapped in obscurity, have for the most part constituted objects for empirical medication The relation of this gland to surrounding organs, and its great distance from the anterior wall of the abdomen, the only point of approach, necessarily offer serious obstacles to diagnosis and direct treatment In a diagnostic point of view I may also refer to another great difficulty—our want of positive knowledge concerning the physiological functions performed by this gland in the process of digestion As the symptomatology of all affections of the pancreas is always obscure, and a probable diagnosis can only be made in cases where the gland has become considerably enlarged by disease, it is apparent that our present clinical knowledge is limited to diseases which increase the size of the organ to a sufficient extent to determine their existence by palpation Primary malignant disease of the pancreas, when it has advanced to such an extent that its presence can be diagnosticated with certainty by physical signs, will have invaded the adjacent tissues to such a degree as to preclude the advisability of an operation, consequently the efforts of the surgeon, for the present at least, must be directed exclusively towards the recognition and treatment of benign affections of this gland Clinical experience does not extend beyond an imperfect knowledge of cysts of the pancreas

The pancreas, like other secretory organs, is prone to become the seat of cystic tumors, the result of obliteration or obstruction of the common duct, or one or more of its branches Cysts originating in this manner are true retention cysts, containing the physiological secretion from the distal portion of the gland tissue, with perhaps accidental products, such as altered secretions, blood, and the products of inflammation

---

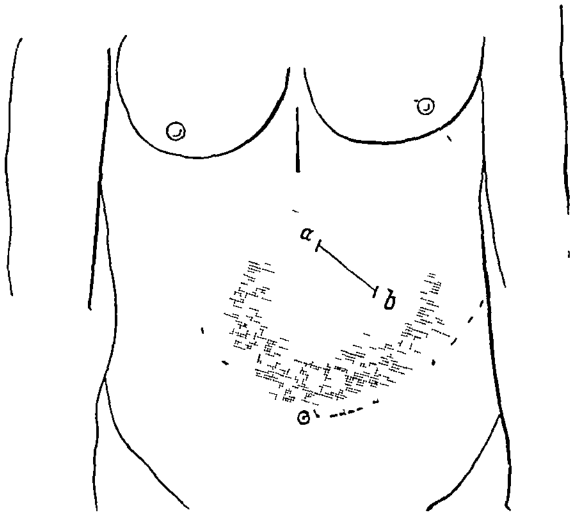
[2] This part of the valuable paper of Dr Senn should have appeared before the part which was published in the JOURNAL of Sept 26 as it constitutes the first part of the paper —ED

In the preparation of this paper it has been my intention to present to you a full report of a case of retention cyst of the pancreas which has recently come under my observation, and, at the same time, bring before you in a compact form the clinical history of similar cases, which will serve as a basis for some general remarks "on the surgical treatment of cysts of the pancreas"

CYST OF PANCREAS, LAPAROTOMY, RECOVERY

Volz, æt 19, laborer, German, was admitted to Milwaukee Hospital, Nov 28, 1884 He is small for his age and not robust but he claims that with one exception, he has never been sick, and that no hereditary tendency to disease exists in his family Five weeks ago, while enjoying perfect health, he was thrown from a wagon striking the ground on the left side of the abdomen, a heavy keg falling upon his back and increasing the force of the fall The pain felt immediately after the accident was confined to his back, at a point where he was struck by the keg, but it was not sufficient in intensity to prevent him from followlowing his occupation as a mason's apprentice In a few days, however, diarrhœa set in, which persisted for two weeks, greatly reducing his strength and weight If he had any fever during this time, it was not sufficiently severe to attract his attention His appetite was not impaired, and, although he vomited occasionally, neither vomiting nor the diarrhœa seemed to be aggravated by the time of eating or the kind or variety of food After two weeks he noticed a tumor in the left hypochondriac region which was round smooth, and painless The tumor increased rapidly in size, and soon gave rise to a sensation of fulness in the stomach, and later on to regurgitation and vomiting soon after meals Appetite slightly impaired At this time the patient was treated for a short time by my friend, Dr F H Day, of Wauwatosa, Wis, who resorted to symptomatic treatment, and, observing no improvement, referred him to me for diagnosis, and, in case it should be deemed advisable, for surgical treatment On his admission to the hospital he presented a considerable degree of emaciation, and complained principally of a sensation of fulness and weight in the region of the stomach, which was always aggravated after meals and only relieved by vomiting On inspection a tumor was found, which occupied nearly the whole epigastric and the entire left hypochondriac region, its most prominent point being to the left of the median line, and about three inches below the xyphoid cartilage Percussion revealed a line of dulness extending from the left nipple to within an inch above the umbilicus, posteriorly the dulness reached from the eighth to the lower margin of the twelfth ribs, in the epigastric region a limited area of tympanitic resonance was discovered along the costal arch of the lower ribs on the right side Palpation showed distinct fluctuation, the wave being conveyed from side to side across the whole area of dulness The tumor was round in contour and presented a smooth surface The measurements were as follows From the left nipple to the lowest point downwards twenty two centimetres, the transverse diameter twenty one centimetres, and the anterior circumference sixty-three centimetres The heart was pushed upwards so that the impulse of the apex could be distinctly felt in the fourth intercostal space The stomach was artificially distended with carbonic acid gas, when it was ascertained that it was pushed to the right and compressed by the tumor The liver appeared to be unaffected by the tumor, as on percussion it was found in its normal location and of natural size Both lumbar regions were tympanitic No evidences of ascites Firm pressure over any part of the tumor could be made without causing pain The peculiar fremitus often felt in cases of echinococcus cysts was absent No pulsations could be felt in the tumor, and no impulse was imparted to it by the underlying abdominal aorta The relative position of the tumor was changed during forcible inspiration and expiration For the purpose of ascertaining the nature of the contents of the tumor a hypodermic needle was thoroughly disinfected and introduced at a point where the tumor was most prominent, and, when in place, the distal end of the syringe moved upward and downward synchronously with the respiratory movements, showing that the adhesions with the parietal peritoneum, if any existed, were slight The fluid which was removed was somewhat viscid and slightly opalescent It was alkaline in reaction and contained a considerable proportion of albumin, as it coagulated on applying heat and nitric acid Under the microscope it showed only a few morphological elements, epithelial cells, a few leucocytes, granular matter, and no hooklets or cholesterine crystals



Space within dotted lines indicates area of dulness, *a–b*, line of incision

By exclusion the diagnosis was narrowed down to one of two things A sterile echinococcus cyst or cyst of the pancreas Against the former spoke the rapid growth of the tumor, its primary origin away from the liver, its favorite location, the presence of considerable amount of albumin, and the absence of hooklets, the presence of which are diagnostic of echinococcus cysts. In favor of a pancreatic cyst spoke the following: The history of traumatism in the region of the pancreas, the rapid growth of the tumor, and the early disturbance of digestion as manifested by diarrhœa and vomiting, presumably caused by the partial or complete retention of the pancreatic secretion. As the treatment remained the same in either case, it was decided to perform laparotomy and stitch the cyst walls to the peritoneal covering of the wound in the absence of adhesions, and to open and drain the cyst after adhesions had formed. This procedure was deemed preferable to the use of the trocar or aspirator as it would with certainty prevent extravasation of the cyst contents into the peritoneal cavity, and the drainage tube would guard against reaccumulation of the fluid, thus affording an opportunity of the cavity undergoing obliteration by adhesion of the inner surfaces of the cyst walls. The patient, being cognizant of the fact that no other form of treatment would promise any relief, readily assented to the operation proposed. Every precaution was observed to render the operation aseptic. The patient was given several baths, the parts were shaved and carefully disinfected with a five per cent. solution of carbolic acid, the instruments, sponges, and operating room being prepared the same as for an ovariotomy. Before ether was administered the stomach was emptied and washed out by means of an elastic stomach tube, with a view to prevent retching and vomiting during and after the operation. An incision five inches in length was made obliquely over the most prominent portion of the tumor, about three inches below and parallel with the left costal arch. A portion of the rectus abdominis muscle was divided. After dividing carefully all the tissues down to the peritoneum all hemorrhage was carefully and completely arrested.

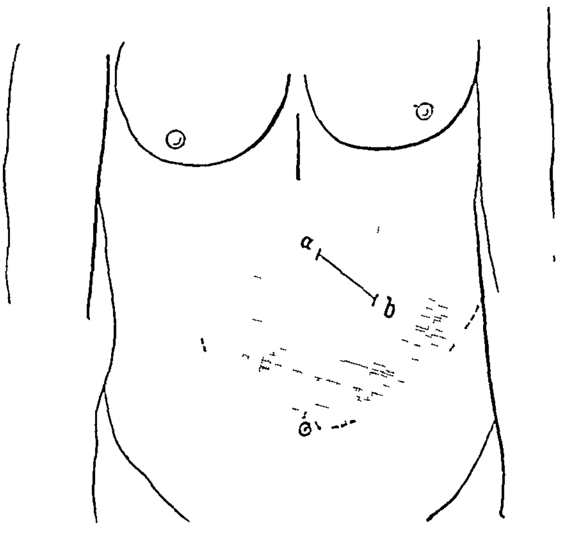
On opening the peritoneal cavity, the omentum was brought into view, the portion exposed containing an artery and a vein of considerable size. As these vessels were placed in a vertical direction, they crossed the wound, and it became necessary to apply a double ligature, the omentum being then incised between them to the extent of about three inches. The omentum was slightly adherent to the parietal peritoneum and the surface of the tumor. Through the omental incision the tumor could be distinctly seen and felt, presenting a smooth, whitish and glistening surface. As it had formed at least slight adhesions, it was decided to complete the operation. This plan was the more willingly adopted, as it was evident that the intra-cystic pressure was great and the cyst walls thin—which would render stitching them to the margins of the wound difficult and unsafe. The surface of the tumor was then seized with two dissecting forceps about an inch apart, and gentle traction made during incision and evacuation of the cyst, so as to prevent all risk of extravasation of fluid into the peritoneal cavity. The peritoneal covering was picked up and nipped, and a grooved director was inserted into the opening made, owing to the thinness of the walls of the sac it penetrated the interior, and fluid escaped along the groove with considerable force. The opening was enlarged with the knife, when the fluid gushed forwards in jets and was caught in basins. The contents were removed as completely as possible by making external pressure and by placing the patient on the side. As the cyst was emptied its walls were drawn forward into the wound and stitched to the peritoneum, which had been previously united with the skin. The interior of the cyst was explored by inserting the index-finger, which passed directly backwards toward the tail of the pancreas. The bottom of the cavity could, however, not be reached. The inner surface of the cyst was smooth. Two large drainage tubes were inserted to the bottom of the cyst, and the remaining portion of the wound united in a similar manner as after ovariotomy, only that the rectus muscle was sutured separately. The fluid removed was estimated at three quarts, and presented the same appearance as that which was removed by exploratory puncture. The wound was dressed with a large antiseptic compress, which was retained *in situ* with an elastic rubber bandage. This bandage made of rubber webbing not only retains the dressing perfectly, allowing at the same time the movements of the chest and abdomen, but has an additional advantage, inasmuch as it exerts equable pressure, an important element in the after-treatment of all abdominal operations.

The patient never vomited during or after the operation, and experienced immediate relief on removing the pressure which was caused by the tumor. The pulse never rose over 90°, and the highest temperature observed was 100° F., the day after the operation. The appetite increased, and no unpleasant subjective symptoms were complained of at any time. On the third day the dressing showed moisture on the external surface, and it was changed. The gauze was saturated with the secretions from the cyst. The wound looked healthy, but the surrounding skin, as far as the dressing had extended, was red and macerated, and the epidermis could be removed in large flakes, leaving beneath a raw surface. The changes in the skin presented the same appearances as described by Kulenkampff and Gussenbauer, and claimed by them to be due to the digestive power of the pancreatic juice. The excoriated surface was sprinkled with salicylic acid, and was again covered with a Lister dressing. On account of profuse secretion from the cyst the dressings were changed every few days, and at every change the skin was found excoriated as far as it had been moistened by the secretion. At the end of the first week the sutures were removed and no further dressings were applied, whereupon the skin healed without suppuration, and only a minimum amount of pus escaped through the fistulous opening with the secretion. The secretion became clearer after the operation, and continued to discharge in varying quantities for almost four weeks. One of the drainage tubes inserted at the time of the operation was removed at the first change of the dressing, and the second was gradually shortened, and entirely removed three weeks after the operation. At the end of the second week, the cyst was explored physiological secretion from the distal portion of the gland tissue, with perhaps accidental products, such as altered secretions, blood, and the products of inflammation

In the preparation of this paper it has been my intention to present to you a full report of a case of retention cyst of the pancreas which has recently come under my observation, and, at the same time, bring before you in a compact form the clinical history of similar cases, which will serve as a basis for some general remarks "on the surgical treatment of cysts of the pancreas"

CYST OF PANCREAS, LAPAROTOMY, RECOVERY

Volz, æt 19, laborer, German, was admitted to Milwaukee Hospital, Nov 28, 1884 He is small for his age and not robust, but he claims that with one exception, he has never been sick, and that no hereditary tendency to disease exists in his family Five weeks ago, while enjoying perfect health, he was thrown from a wagon striking the ground on the left side of the abdomen, a heavy keg falling upon his back and increasing the force of the fall The pain felt immediately after the accident was confined to his back, at a point where he was struck by the keg, but it was not sufficient in intensity to prevent him from followlowing his occupation as a mason's apprentice In a few days, however, diarrhœa set in, which persisted for two weeks, greatly reducing his strength and weight If he had any fever during this time, it was not sufficiently severe to attract his attention His appetite was not impaired, and, although he vomited occasionally, neither vomiting nor the diarrhœa seemed to be aggravated by the time of eating or the kind or variety of food After two weeks he noticed a tumor in the left hypochondriac region which was round smooth, and painless The tumor increased rapidly in size, and soon gave rise to a sensation of fulness in the stomach, and later on to regurgitation and vomiting soon after meals Appetite slightly impaired At this time the patient was treated for a short time by my friend, Dr F H Day, of Wauwatosa, Wis, who resorted to symptomatic treatment, and, observing no improvement, referred him to me for diagnosis, and, in case it should be deemed advisable, for surgical treatment On his admission to the hospital he presented a considerable degree of emaciation, and complained principally of a sensation of fulness and weight in the region of the stomach, which was always aggravated after meals and only relieved by vomiting On inspection a tumor was found, which occupied nearly the whole epigastric and the entire left hypochondriac region, its most prominent point being to the left of the median line, and about three inches below the xyphoid cartilage Percussion revealed a line of dulness extending from the left nipple to within an inch above the umbilicus, posteriorly the dulness reached from the eighth to the lower margin of the twelfth ribs, in the epigastric region a limited area of tympanitic resonance was discovered along the costal arch of the lower ribs on the right side Palpation showed distinct fluctuation, the wave being conveyed from side to side across the whole area of dulness The tumor was round in contour and presented a smooth surface The measurements were as follows From the left nipple to the lowest point downwards twenty-two centimetres, the transverse diameter twenty one centimetres, and the anterior circumference sixty-three centimetres The heart was pushed upwards so that the impulse of the apex could be distinctly felt in the fourth intercostal space The stomach was artificially distended with carbonic acid gas, when it was ascertained that it was pushed to the right and compressed by the tumor The liver appeared to be unaffected by the tumor, as on percussion it was found in its normal location and of natural size Both lumbar regions were tympanitic No evidences of ascites Firm pressure over any part of the tumor could be made without causing pain The peculiar fremitus often felt in cases of echinococcus cysts was absent No pulsations could be felt in the tumor, and no impulse was imparted to it by the underlying abdominal aorta. The relative position of the tumor was changed during forcible inspiration and expiration For the purpose of ascertaining the nature of the contents of the tumor a hypodermic needle was thoroughly disinfected and introduced at a point where the tumor was most prominent, and, when in place, the distal end of the syringe moved upward and downward synchronously with the respiratory movements, showing that the adhesions with the parietal peritoneum, if any existed, were slight The fluid which was removed was somewhat viscid and slightly opalescent It was alkaline in reaction and contained a considerable proportion of albumin, as it coagulated on applying heat and nitric acid Under the microscope it showed only a few morphological elements, epithelial cells, a few leucocytes, granular matter, and no hooklets or cholesterine crystals



Space within dotted lines indicates area of dulness, *a-b*, line of incision

By exclusion the diagnosis was narrowed down to one of two things A sterile echinococcus cyst or cyst of the pancreas Against the former spoke the rapid growth of the tumor, its primary origin away from the liver, its favorite location, the presence of considerable amount of albumin, and the absence of hooklets, the presence of which are diagnostic of echinococcus cysts. In favor of a pancreatic cyst spoke the following: The history of traumatism in the region of the pancreas, the rapid growth of the tumor, and the early disturbance of digestion as manifested by diarrhœa and vomiting, presumably caused by the partial or complete retention of the pancreatic secretion. As the treatment remained the same in either case, it was decided to perform laparotomy and stitch the cyst walls to the peritoneal covering of the wound in the absence of adhesions, and to open and drain the cyst after adhesions had formed. This procedure was deemed preferable to the use of the trocar or aspirator, as it would with certainty prevent extravasation of the cyst contents into the peritoneal cavity, and the drainage tube would guard against reaccumulation of the fluid, thus affording an opportunity of the cavity undergoing obliteration by adhesion of the inner surfaces of the cyst walls. The patient, being cognizant of the fact that no other form of treatment would promise any relief, readily assented to the operation proposed. Every precaution was observed to render the operation aseptic. The patient was given several baths, the parts were shaved and carefully disinfected with a five per cent. solution of carbolic acid, the instruments, sponges, and operating room being prepared the same as for an ovariotomy. Before ether was administered the stomach was emptied and washed out by means of an elastic stomach tube, with a view to prevent retching and vomiting during and after the operation. An incision five inches in length was made obliquely over the most prominent portion of the tumor, about three inches below and parallel with the left costal arch. A portion of the rectus abdominis muscle was divided. After dividing carefully all the tissues down to the peritoneum all hemorrhage was carefully and completely arrested.

On opening the peritoneal cavity, the omentum was brought into view, the portion exposed containing an artery and a vein of considerable size. As these vessels were placed in a vertical direction, they crossed the wound, and it became necessary to apply a double ligature, the omentum being then incised between them to the extent of about three inches. The omentum was slightly adherent to the parietal peritoneum and the surface of the tumor. Through the omental incision the tumor could be distinctly seen and felt, presenting a smooth, whitish and glistening surface. As it had formed at least slight adhesions, it was decided to complete the operation. This plan was the more willingly adopted, as it was evident that the intra-cystic pressure was great and the cyst walls thin—which would render stitching them to the margins of the wound difficult and unsafe. The surface of the tumor was then seized with two dissecting forceps about an inch apart, and gentle traction made during incision and evacuation of the cyst, so as to prevent all risk of extravasation of fluid into the peritoneal cavity. The peritoneal covering was picked up and nipped, and a grooved director was inserted into the opening made, owing to the thinness of the walls of the sac it penetrated [illegible] the interior, and fluid escaped along the [illegible] considerable force. The opening [illegible] the knife, when the fluid gushed forward in [illegible] was caught in basins. The contents were [illegible] as completely as possible by making external [illegible] and by placing the patient on the side. [illegible] was emptied its walls were drawn forward into the wound and stitched to the peritoneum, which had been previously united with the skin. The interior of the cyst was explored by inserting the index finger, which passed directly backward toward the [illegible] the pancreas. The bottom of the cavity could, however, not be reached. The inner surface of the cyst was smooth. Two large drainage tubes were inserted to the bottom of the cyst, and the remaining portion of the wound united in a similar manner as after ovariotomy, only that the rectus muscle was united separately. The fluid removed was [illegible] three quarts, and presented the same appearance as that which was removed by exploratory puncture. The wound was dressed with a large antiseptic compress, which was retained *in situ* with an elastic rubber bandage. This bandage made of rubber webbing not only retains the dressing perfectly, allowing at the same time the movements of the chest and abdomen, but has an additional advantage, inasmuch as it exerts equable pressure, an important element in the after treatment of all abdominal operations.

The patient never vomited during or after the operation, and experienced immediate relief on removal of the pressure which was caused by the tumor. The pulse never rose over 90°, and the highest temperature observed was 100° F., the day after the operation. The appetite increased, and no unpleasant subjective symptoms were complained of at any time. On the third day the dressing showed moisture on the external surface, and it was changed. The gauze was saturated with the secretions from the cyst. The wound looked healthy, but the surrounding skin, as far as the dressing had extended, was red and macerated, and the epidermis could be removed in large flakes, leaving beneath a raw surface. The changes in the skin presented the same appearances as described by Kulenkampff and Gussenbauer and claimed by them to be due to the digestive power of the pancreatic juice. The excoriated surface was sprinkled with salicylic acid, and was again covered with a Lister dressing. On account of profuse secretion from the cyst the dressings were changed every few days, and at every change the skin was found excoriated as far as it had been moistened by the secretion. At the end of the first week the sutures were removed and no further dressings were applied, whereupon the skin healed without suppuration, and only a minimum amount of pus escaped through the fistulous opening with the secretion. The secretion became clearer after the operation, and continued to discharge in varying quantities for almost four weeks. One of the drainage tubes inserted at the time of the operation was removed at the first change of the dressing, and the second was gradually shortened, and entirely removed three weeks after the operation. At the end of the second week, the cyst was ex with a disinfected probe which passed to a depth of eight inches in the direction of the tail of the pancreas. The fistulous tract soon became live with granulations, and grew smaller in length and diameter so that at the end of eight weeks it was very narrow, so as to admit only a small probe, which could be passed only to a depth of four inches. The skin around the fistulous opening has been drawn inward, forming a deep funnel shaped depression.

Jan. 22, 1885. Patient discharged cured. Fistula completely closed. Retraction of cicatrix very marked. General health good, digestion perfect. No swelling can be felt in the region of the pancreas.

Remarks.—The clinical history is somewhat similar to analogous cases which will be referred to in this paper. It was my intention to collect some of the secretion for the purpose of ascertaining its digestive properties on different articles of food, but before this could be done the amount secreted daily became so small that it was impossible to obtain corroborative diagnostic evidence from this source. The anatomical location of the tumor, its relations to the surrounding organs, its rapid growth, and the character of its contents, can leave no possible doubt that we had to deal with a genuine retention cyst of the pancreas. The question naturally arises, what was the cause of the obstruction? The history of the case points clearly to traumatism as the exciting cause. The patient had been in good health until he received the injury, and since that time he had not been well, although he continued at his work for some time afterward. Whether the diarrhœa from which he suffered for the first two weeks resulted from injury to the pancreas, we are unable to prove, but it may be possible that a retention of the pancreatic secretion occurred after the traumatism, that diarrhœa may have been produced by the absence of the fluid in the intestinal tract. As the patient at this time was not under medical observation, the character of the stools was not ascertained. As the injury was inflicted in the region of the pancreas, it is reasonable to assume that the pancreatic duct and the parenchyma of the gland were lacerated at a certain point, producing obstruction to the outflow of the secretion from the distal portion of the organ, the nature of the injury and the manner of obstruction being the same as in cases of rupture of the male urethra. It would be difficult to imagine that the common duct could be distended by the accumulation of the retained fluid to such an enormous extent in such a remarkably short time hence we are forced to conclude that laceration of the duct took place, and that the pancreatic fluid infiltrated the gland, and the cyst formed at the expense of its parenchyma and by distension of the capsule of the organ. The cyst wall anteriorly was so thin that after cutting the peritoneal covering the grooved director penetrated directly into the interior of the cyst without using more than the slightest force, which would show that nothing but a little connective tissue was interposed between the peritoneum and the cyst-contents. The rapid growth of the cyst would indicate that the obstruction occurred at some distance from the caudal extremity of the gland, thus making a considerable portion of the secreting tissue contributory to the formation of the cyst. The early cessation of the discharge of the secretion through the abnormal outlet would tend to prove either that after the removal of the intra cystic pressure the duct again became permeable, and thus furnished a free passage to the secretions into the intestinal canal through the natural channel, or that the gland tissue in the vicinity and distal to the cyst had been destroyed. In regard to the operation, it is necessary to say that I deviated from the usual plan in not making the incision through the linea alba. The incision was made over the most prominent part of the tumor, for the following substantial reasons:

1. If adhesions had formed, they would naturally begin at a point where the tumor impinged most firmly against the anterior abdominal wall.

2. Incision over the most prominent portion of the cyst would afford the best point for effective drainage.

The band of connective tissue which would result from atrophy and obliteration of the cyst would form a permanent bridge between the cicatrix of the abdominal wound and the gland, consequently it is advisable to establish this necessary evil where it will do the least harm by interfering with the functions of important organs.

Aspiration of the cyst was not practised, because the exploratory puncture had demonstrated that firm adhesions had not taken place, and in the absence of these it was feared that some of the cyst contents might escape into the peritoneal cavity and produce peritonitis. The maceration of the skin was the result of the digestive action of the pancreatic juice, and this phenomenon furnished strongly corroborative diagnostic evidence in this as well as in previous cases.

The literature on the subject of cysts of the pancreas is extremely meagre, and after diligent search I have only been able to find an account of the following cases, of which I will give a brief report.

Case II.—Kulenkampff's case.[1] E., male, æt. 39, laborer, otherwise healthy, received a number of heavy blows on the abdomen on March 22, 1881. The blows were received the patient believes, about the umbilicus and in the direction from below upwards. When examined a few hours later, no external signs of contusion could be seen, although he complained of intense pain in the upper abdominal and right hypochondriac regions. Great tenderness on pressure. On the right side posteriorly, above the diaphragm, dulness over an area three inches in height. As the patient complained of lancinating pains in the same locality, and respiration was difficult, the attending physician was induced to diagnosticate traumatic pleurisy. In a few days the febrile symptoms and pain subsided, and in three weeks the patient seemed to be convalescent. Occasional attacks of pain in the hepatic and epigastric regions remained, and also tenderness on pressure. Physical examination at this time yielded only a negative result. Toward the latter part of May, a swelling made its appearance which seemed to take its origin from the liver. This swelling increased in size until September, when the following conditions were noted. In the epigastric region a round, dense, non-fluctuating tumor can be felt, of the size of a double fist. The larger part of the swelling is located on the right side of the mesial line. Its lower margin extends to within one and a half inches of the umbilicus. Percussion dulness continues with liver, giving the impression as though the tumor sprang from the left lobe of this organ. Tumor ascends and descends during the respiratory movements. Pulsation in an anterior direction. No bruit. Palpation unsatisfactory on account of the contraction of the recti muscles. Appetite and digestion not impaired. Temperature normal, no icterus. Examination of urine and stools furnished no clue to the diagnosis.

---

[1] Ein Fall von Pankreasfistel. Berliner Klinische Wochenschrift, Feb. 13, 1882.

As from the existing signs and symptoms no diagnosis could be made, it was decided to render the tumor more accessible by dividing the tissues down to the peritoneum. On September 14, an incision was made through the linea alba down to the peritoneum. To the touch the tumor, which moved freely, imparted the sensation of a tense, nodular liver, as in cirrhosis of this organ. The trocar of an aspirator was now introduced towards the right of the mesial line, and after penetrating through dense tissue the distance of a centimetre, a cavity was reached, from which about a quart of clear fluid was evacuated. The peritoneal cavity was not opened and the wound was packed with gauze, over which an antiseptic dressing was applied. The diagnosis of an echinococcus cyst, which had already been entertained, was strengthened by this examination. The fluid removed coagulated spontaneously on standing for some time, also on applying the tests for albumen. It contained no succinic acid. In the deposit, which was very scanty, blood and lymph corpuscles were discovered. On September 20 the peritoneum was incised and stitched to the skin. The finger which was introduced into the peritoneal cavity came in contact with a freely movable and nodular tumor which was supposed to be attached to the liver. Its size was fully as large as before the last operation. The incision was again filled with gauze, and four days later, adhesions having taken place, the tumor was incised, and about a quart of the same kind of fluid escaped through the wound. On digital exploration it was ascertained that the inner surface of the cyst was lined with mucous membrane, which was studded with polypoid growths. A large drainage tube was inserted and a Lister dressing applied. During the next two weeks there was no febrile reaction, the tumor disappeared, and large quantities of the same clear fluid escaped through the fistulous opening. On October 10 the secretion had diminished greatly, and the tract had been reduced to the size of an ordinary lead pencil. Injections of iodine were made with a view to hasten the obliteration of the cyst, but this procedure excited pain, emesis, and renewed secretion of fluid, of which from one fourth to three fourths of a quart were evacuated during twenty four hours. Cauterisation with nitrate of silver produced no better result. The skin remained in a state of maceration wherever it was moistened by the secretion, in spite of often repeated changes of dressings. This peculiar condition of the skin first aroused the suspicion in Kulenkampff's mind that he was dealing with a fistula of the pancreas. He therefore collected some of the fluid and handed it to a chemist for analysis. The fluid was almost clear, colorless, frothing upon being shaken, slightly alkaline in reaction. It contained but few inorganic salts, and coagulated on applying heat and nitric acid. It contained no succinic acid. Experiments were made to ascertain its effects on coagulated albumen, neutral fats, and starch, the substances being kept at a temperature of 20–25° C. Special care was taken to preserve its alkaline reaction. A fresh paste made of four grms. wheaten flour and fifty grms. water was rendered very thin by the fluid. Fehling's solution showed the presence of 0.96 grms. glucose. Coagulated albumen of an egg, kept in a one fourth per cent. solution of salicylic acid it showed no appreciable change. 0.195 grms. leucin and tyrosin were obtained from it. Three decigrammes freshly prepared lard were melted and subjected to the action of the fluid. A perfect emulsion was formed which had not given off free fat after the lapse of twelve hours. The chemical examination showed in 100 parts: 3.65 parts of albumen which coagulated on addition of alcohol and again was soluble in water, 8.57 parts of organic matter of various kinds, 8.09 parts of inorganic substances. Kulenkampff is inclined to the belief that the traumatism caused some parts of the pancreas to become inflamed, thus causing a constriction or obliteration in the duct of Wirsung or some of its branches. As long as the fistula continued to discharge the patient became emaciated, but there was no disturbance of digestion. The urine at no time contained sugar. It was noticed that the secretion was more profuse during the afternoon. The patient recovered completely after the closure of the fistula.

Remarks.—This case illustrates well the difficulties which are met with in diagnosticating affections of the pancreas. Repeated examinations carefully made, direct exploration of the tumor at the time of the second operation, failed to throw sufficient light upon the case to enable the attending surgeon to make a positive diagnosis. The peculiar effect of the pancreatic juice upon the skin turned the attention of the operator in the right direction, and the chemical examination of the fluid, and the physiological tests to which it was subjected, finally resulted in a positive and correct conclusion.

In the next case, the operator asserts to have made a *probable* diagnosis before the operation.

CASE III.—Gussenbauer's Case.[1] Male patient, musician, æt. 40, who has always been in good health and not affected by any hereditary taint, was taken suddenly ill after having, on a festive occasion, indulged too freely in the pleasures of the table. He complained of nausea, acute pain in the stomach, and, after having taken more alcoholic stimulants to relieve the symptoms, he vomited repeatedly. In a few days he recovered from this attack and remained well for two weeks, when he discovered a swelling in the region of the stomach, which increased rapidly in size, so that after two weeks it caused a visible bulging in the epigastric region The appetite now became impaired, the patient complaining of a sensation of fulness after meals, accompanied by frequent eructations During the next month he vomited after meals and became greatly emaciated The treatment resorted to had no effect in arresting the rapid growth of the tumor, which soon became the source of radiating pains through the lumbar and sacral regions When he was first seen by Gussenbauer, Dec 21, 1882, about ten weeks after the illness had commenced, he was emaciated, skin pale and of a dirty grayish brown color Respiration thoracic, pulse full and regular Percussion showed slight dulness in the right side (sternal region) from the third rib downward, complete dulness from the fifth rib In the mammary line slight dulness at the upper margin of the fourth, complete dulness from fifth rib downward, in the axillary region, slight dulness over seventh, and complete dulness from eighth rib On the left side slight dulness began at the upper margin of the third and extended to the eighth in the axillary line Auscultation showed vesicular breathing on both sides of the chest On examination of the abdomen, a prominent swelling attracted the attention, which extended over the right and left supraumbilical regions, and from the left costal arch into the right hypochondriac region In the middle line the tumor measured 18½ centimetres from the xiphoid cartilage to two inches below the umbilicus, from the left costal cartilage to the right hypochondrium, 22 centimetres Over the anterior surface of the tumor, as far as it was not covered by the left lobe of the liver, percussion elicited clear, full tympanitic resonance If the abdominal wall was pressed against the tumor the percussion became dull On inflating the stomach it could be seen rising above the tumor, its great curvature was easily mapped out by inspection and percussion The transverse colon seemed to crop anteriorly over the middle of the tumor It was movable only to a slight degree, and seemed to follow the respiratory movements Tenderness on deep and firm pressure No ascites Bowels somewhat constipated, stools natural, with no admixture of fat No abnormal constituents in urine The rapid growth of the tumor and its location in the bursa omentalis behind the stomach and transverse colon, led Gussenbauer to make a probable diagnosis of a cyst of the pancreas or the suprarenal capsule

---

[1] Zur operativen Behandlung der Pankreascysten. Archiv f. Klin. Chir., vol. xxix, p. 355.

As the patient was in a critical condition, and all other measures had failed to afford relief, the only hope centred on a surgical operation, which was performed December 22, 1882 An incision was made in the linea alba about five inches in length, and the peritoneal cavity opened to the same extent The stomach and great omentum were seen to cover the anterior surface of the tumor The omentum was detached from the great curvature of the stomach for about three inches, several arteries were compressed temporarily and subsequently ligated Through the omental incision the tumor came into view, covered by peritoneum Fluctuation was now distinctly felt in the tumor The upper and lower portions of the incision were closed, the parietal peritoneum was sutured to the external skin, and the anterior surface of the cyst to the margins of the wound Through one of the punctures in the cyst wall a dark brown fluid escaped, and, as the suture was tied, the opening enlarged and the fluid escaped in a jet A part of the contents of the cyst were evacuated by means of a trocar, in order to diminish the intracystic pressure and allow of a more perfect fixation of the cyst walls to the wound When this had been done an incision three centimetres in length was made into the tumor, from which altogether 1,900 cubic centimetres of fluid escaped Exploration of the interior of the cyst with the finger and sound indicated no traces of a solid tumor, but a smooth membrane lining the inner walls The lower portion of the cyst walls were covered with black masses, which were easily detached and removed without giving rise to bleeding The cavity was washed out with a solution of thymol, a large drainage tube introduced, and iodoform dressing applied The fluid was of a grayish black color, and contained in suspension large quantities of masses of pigment a few red corpuscles, in a state of degeneration, representing all forms of retrograde changes The specific gravity of the fluid was 1 610 and its reaction alkaline The dark color was due to the pigment, which was found to be soluble in concentrated caustic soda and in acid alcohol Spectrum analysis showed the presence of hæmatin, but not not of hæmoglobin Further tests showed that it contained albumen, a body resembling mucin, and a material soluble in alcohol, but no bile pigment, metalbumen, peptones, or sugar When the dressings were changed on the third day, the skin appeared to be macerated, which necessitated in the future a daily change of dressing The patient was relieved promptly by the operation, and the wound healed without suppuration After a few days the discharge from the fistula became clear, and on examination it was found to contain leucin and tyrosin Its reaction was alkaline, it digested albumen, and converted starch into sugar Patient made a good recovery and was dismissed three weeks after the operation with a small fistulous opening, which continued to discharge a small amount of pancreatic fluid During the time he was kept under observation the fistula closed several times, and each time he suffered from a rise in temperature, which continued until the fistula opened and discharged again

Remarks —The origin of the cyst in this case was believed to be a hæmatoma of the pancreas This assumption, however, lacks demonstation, and it is just as logical to assume that the cyst originated in the usual way from an obstruction, and that the blood in the cyst contents was an accidental product The obstinacy of the fistula to close permanently would lead to the suspicion that the obstruction was of a permanent nature, either by the impaction of a calculus in the common duct, or obliteration of this channel by cicatricial contraction, the result of chronic inflammation

The next three cases of cysts of the pancreas were mistaken for ovarian cysts, and the operation of ovariotomy was performed, when the nature of the cysts was discovered, in one instance during the operation, and in the remaining two at the necropsy.

CASE IV.—Bozeman's Case.[1] The patient was a lady 41 years of age, and perfectly healthy up to seven years ago, with the exception of occasional attacks of indigestion. Seven years ago she experienced for the first time pain in the right iliac region, extending down the right thigh and at times attended with numbness. Five years ago the abdomen began to enlarge upon the left side, with a corresponding flatness upon the right side. The swelling increased slowly up to six weeks ago, when it suddenly began to grow rapidly. Finally, it filled symmetrically the entire abdominal cavity. At the same time the patient became emaciated and weak. Dr. T. G. Richardson, of New Orleans, who examined her at this time, diagnosticated the case as one of cystic tumor of one of the ovaries, and advised the patient to consult Dr. Bozeman. The patient entered the Woman's Hospital in New York, Nov. 19, 1881, where she came under Dr. Bozeman's care. The previous diagnosis was confirmed by Drs. Bozeman, Thomas, and Emmet. December 2 an operation was performed for the removal of the supposed ovarian cyst. Full antiseptic precautions were observed before and during the operation. When the tumor was reached through an incision below the umbilicus, its appearance was identical with that of an ordinary ovarian cyst, only that its color was of a more deep pearly hue. With a trocar two and one half gallons of fluid were evacuated. After the fluid had nearly escaped about two-thirds of the cyst was drawn through the incision, and then for the first time the operators' suspicions were aroused that it was not ovarian. An exploration of the abdominal cavity revealed the presence of both ovaries in a healthy condition. The origin of the cyst was traced to the upper part of the abdomen. The incision was enlarged upwards two inches above the umbilicus. Further examination showed that the stomach had been crowded against the diaphragm by the tumor, while the intestines were displaced in the opposite direction. The cyst was found adherent to the transverse mesocolon. In tracing the cyst walls still further the pancreas was reached, where a large vein was discovered which was very tortuous and subsequently identified as the splenic. As this vein was in close relationship to the pedicle, its presence rendered the operation more difficult. The tail of the pancreas lay in contact with the side of the cyst wall and firmly adherent to it to the extent of two inches. When this portion was separated the organ spread out and presented its natural appearance. The cyst sprang from the pancreas at the junction of the outer with the inner two thirds, the pedicle being three fourths of an inch in length and about the same in thickness. The veins of the pedicle were very large. The pedicle was transfixed and secured in a double ligature and cut off. On examination of the cyst it was discovered that a portion of it remained attached to the pedicle, this was subsequently completely removed by a careful dissection. The artery which supplied the cyst was as large as the brachial, and appeared to be a branch of the splenic. Very little bleeding attended the operation, and no ligatures were required. The fluid removed was of a light brownish color, acid reaction, and a specific gravity of 1.020. Tumor and contents weighed twenty and one half pounds. Quinine, stimulants and opiates were given after the operation. The highest temperature, 101.5° F., was noted on the third day, the pulse never rose above 98. After omitting the quinine, the temperature rose to 102.8° F. on the eighth day, when quinine, in ten grain doses every six hours, reduced the temperature to nearly normal in the course of thirty-six hours. From this time the improvement continued uninterruptedly to the time when the patient was discharged cured on the thirty-eighth day.

CASE V.—K. von Rokitansky's case reported by Zukowski.[1] The patient was a female 36 years of age who had suffered with symptoms indicative of ovarian cyst for nearly three years. The tumor was first noticed in the upper portion of the abdominal cavity. Laparotomy was performed Feb. 27, 1881. The usual incision was made in the linea alba, and the supposed ovarian cyst was found behind the great omentum, stomach, and transverse colon. The cyst wall adhered firmly to the surrounding organs, and on attempting to separate the adhesions between it and the transverse colon, a rent was made in the bowel two ctms. in length. The tear was at once closed with five sutures. The adhesions were so numerous, firm and vascular, that complete extirpation of the entire cyst was found impossible, consequently the detached portion of the cyst was crushed off with an ecraseur, and the stump fastened in the abdominal incision and the wound drained and closed. During the operation the cyst ruptured and a portion of its contents escaped into the peritoneal cavity. Fifty ligatures were applied in preventing and securing hemorrhage. After the operation the patient collapsed and came nearly dying on the table. She rallied from the immediate effects of the operation but died on the tenth day from suppurative peritonitis. Sometime before death, fecal matter escaped through the opening left by the drainage tube. At the autopsy it was shown that the remaining portions of the cyst were connected with the pancreas. Of this organ only the head was found in a normal condition, of the body only a few remnants remained, while the tail had disappeared completely.

CASE VI.—Luecke's Case, reported by Luecke and Klebs. A female, 43 years old, with the exception of bronchial catarrh had always been in good health. In July, 1866, at the time when menstruation should have appeared, she experienced a severe pain in the right hypochondriac region, where a swelling soon afterward made its appearance. The tumor gradually increased in size and soon occupied the entire abdominal cavity. During the menstrual period the swelling always became tender and painful. She was admitted to the hospital under Luecke's care,

[1] Removal of a cyst of the pancreas weighing 20½ pounds. Medical Record, Jan. 14, 1882.

[1] Grosse Cyste des Pankreas. Laparotomie. Tod. Wiener med. Presse, 1881, Nov. 15.

Beitrag zur Ovariotomie und zur Kenntniss der Abdominalgeschwuelste. Virchow's Archiv, vol. xli, p. 9.

Nov 29, of the same year, and then appeared pale and emaciated She complained of difficulty in breathing, all other functions were unimpaired The abdomen was symmetrically enlarged, its greatest circumference measured ninety five ctms The distance from the xiphoid cartilage to the umbilicus measured fourteen ctm , from the umbilicus to the pubes eighteen ctm Percussion revealed dulness over middle of the abdomen as far as half way between the umbilicus and xiphoid cartilage Lumbar regions tympanitic An examination, per vaginam and rectum showed that the uterus was displaced backward and toward the left side, upon its posterior surface a hard nodule could be felt Tumor appeared to have no connection with the uterus On Dec 1, menstruation set in with severe pain in the lower part of the abdomen No change in temperature or pulse rate Dec 6, the tumor was tapped at a point to the left of the median line, and twenty three pints of a turbid yellowish fluid were evacuated After tapping, a movable tumor was felt in the left side of the abdominal cavity, which was regarded as the collapsed sac of the ovarian cyst The fluid removed contained only a small amount of albumen The microscopic examination showed the presence of large pale cells, some of them filled with granular matter The condition of the patient was considerably improved by the tapping Four days after the operation the cyst was again filling rapidly, and on percussion it seemed to occupy the middle of the abdomen, its upper margin being somewhat below the umbilicus Dec 22, the labia majora and lower extremities were œdematous and the tumor was as large as before tapping Jan 1, 1867, she suffered from a severe attack of dyspnœa during the night, at this time the area of dulness over the tumor had extended to within two inches of the ensiform cartilage, the umbilical depression was effaced, and the lumbar regions were resonant on percussion On the following day the patient was removed to a private dwelling where abdominal section was performed After cutting through the skin and muscular layers in the linea alba, a thin smooth and very vascular membrane protruded through the wonnd Through a small puncture which was made into this membrane, a milkwhite fluid escaped A trocar was pushed through the membrane and a large amount of the same fluid poured out On making traction upon the membrane the umbilical depression was restored This circumstance, as well as the difficulty which was experienced in an attempt to separate the membrane and the prolapse of the small intestine which now occurred, combined to prove that the supposed cyst wall was the parietal peritoneum The abdominal cavity was opened and on exploration both ovaries were found normal in structure and position The abdominal wound was closed with two rows of sutures The fluid removed measured 27½ pints and resembled milk in its gross appearance, it coagulated spontaneously and contained in suspension the same morphological elements as the fluid removed by tapping, with the exception that in addition numerous fat globules were found The patient died Jan 5, the symptoms during her illness indicating diffuse peritonitis The post mortem examination was made by Professor Klebs Intestines crowded upwards, the transverse colon studded with numerous white or myxomatous nodules, very much contracted, forming a curve with the concavity directed upward, being separated from the stomach by a cyst with thin walls The anterior wall of this cyst was made up of the lesser omentum On opening the cyst, a large quantity of fluid escaped resembling in every particular the fluid which had been removed from the peritoneal cavity The floor of the cyst was covered with nodules composed of grayish jelly-like masses The principal portion of this material belonged to the pancreas This organ had been transformed into a mass four inches in width and twelve inches in length, and was composed almost entirely of gelatinous nodules, in the centre of the mass the common duct could be identified The mesentery contained numerous miliary nodules, and in Douglas's pouch large nodular masses were found Left lateral ligament also contained gelatinous nodules Remaining abdominal organs healthy The microscopical appearances were characteristic of colloid cancer The disease had evidently its primary origin in the pancreas

Remarks —Although this case does not properly come within the scope of this paper it presents, however, a few important and interesting points which have a direct bearing on the subject before us The disease was malignant from the beginning, and originated primarily either in the capsule or the parenchyma of the pancreas, and extended from there by continuity to the serous lining of the abdominal viscera A cyst formed in the bursa omentalis anteriorly to the pancreas which had no direct communication with the peritoneal cavity The walls of this cyst were made up of adjacent organs The cyst, occupying the same location as true retention cysts of the pancreas, gave rise to the same signs and symptoms After the removal of the ascitic fluid, the hydropic bursa omentalis remained and was displaced toward the left side, and thus simulated to perfection on a movable cyst Refilling of the cyst took place more rapidly than the accumulation of fluid in the peritoneal cavity In a diagnostic point of view, the severity of the pain and presence of nodules which were felt through the vagina and rectum should have aroused suspicion in regard to the benign character of the tumor, as their presence invariably indicate the existence of malignant disease

In the following case the cyst of the pancreas was mistaken for an abscess

Case VII —Reported by Thiersch[1] A case of pancreatic fistula was admitted to the hospital with the following history The patient, a stone-cutter, 38 years of age, in previous good health, was taken suddenly ill while at work He complained of nausea and a sensation of great lassitude A tumor developed rapidly in the region of the stomach The rapidity with which the tumor appeared and the distinct fluctuation which could be felt, led the attending physician to diagnosticate an abscess in the anterior abdominal wall An incision was made to evacuate the contents af the abscess, but, in place of finding pus, the operator, after cutting through the peritoneum, discovered a cystic tumor of the abdominal cavity. The wound was packed and incision of the cyst postponed until adhesions should form between the anterior surfaces of the tumor and the margins of the wound. Two and a half weeks after the incision was made, the cyst was laid open, and about three quarts of a chocolate colored fluid escaped. As the fistula which formed manifested no tendency to close, the patient sought relief in the hospital. The fistula secreted a moderate amount of a thin serous fluid. The chemical examination for pancreatic juice yielded a negative result. Thiersch dilated the fistulous tract, and ascertained by further examination that the tract was outside the parietal peritoneum and reached so far as the spinal column and the tail of the pancreas. Thiersch was of the opinion that the cyst originated from a hæmatoma of the pancreas and considered this the first case of recovery after such a lesion.

---

[1] Berliner Klin Wochenschrift 1881

Remarks.—If the statement is correct that at the first operation the peritoneal cavity was opened and the wound packed, and that the cyst was opened after firm adhesions had taken place, it is difficult to understand how the fistulous tract could be located outside of the peritoneal cavity, as Thiersch asserts. The location and rapid growth of the tumor, as well as the conditions found at the first operation, would certainly indicate the presence of a true retention cyst complicated by hæmorrhage from the beginning or during the growth of the cyst. Although it is stated that the chemical examination of the fluid secreted yielded only a negative result, positive proof is lacking that it was not pancreatic juice, and we are entitled to the belief that the case was one of cyst of the pancreas, and the fistula a true pancreatic fistula.

In all cases reported so far, with the exception of the fatal cases, it had been impossible to learn the exact seat and nature of the cause of obstruction. For the purpose of throwing some light on this part of our subject, I will refer briefly to a few post mortem specimens which illustrate at least one variety of obstruction.

Prof. von Recklinghausen[1] gives the result of post mortem examination in two cases of cystic disease of the pancreas in patients who had died of diabetes mellitus. The first case was a male, 40 years of age, who had suffered from diabetes mellitus for four years. The specific gravity of the urine was 1.030, and it contained from four to five per cent. of sugar. At the necropsy it was discovered that the pyloric end of the stomach was pushed forward by a large tumor, the lower portion of which was hidden behind the transverse mesocolon, which had been the seat of inflammation and cicatrization. The stomach was connected with the tumor by slight adhesions, but aside of a few hæmorrhagic erosions beneath the mucous membrane, it showed no further signs of disease. Duodenum normal, ductus choledochus permeable. Portal vein passed along the lower right margin of the tumor, where it was somewhat flattened and compressed. Splenic vein slightly dilated. Between the right border of the tumor and the duodenum the head of the pancreas could be seen, presenting a healthy appearance. The common pancreatic duct was pervious at its duodenal extremity and had not suffered any alterations in the head of the gland, but in the body it approached the tumor directly, and was no longer surrounded by gland tissue, but by dense connective tissue which connected the head of the pancreas with the tumor. At the point where the duct terminated in the tumor its lumen was completely filled with a calculous concretion the size of a pea. The tumor was as large as a child's head, nearly round, and consisted of a dense sac which contained a thin, yellowish fluid. In the fluid cholesterine and fat crystals could be seen with the naked eye. On standing, it deposited a white sediment which, under the microscope, showed granular cells and *debris* of cells. The cyst wall was of uniform thickness, measuring about three mm. The sections appeared somewhat gray, at some points interspersed with a slate color. The inner surface of the cyst on the whole was smooth, with isolated thickened patches resembling the sclerotic patches in atheromatous arteries. At some points the inner surface is somewhat elevated by thick membranes of a pearly, glistening appearance and gray color, which could be easily detached. The surface underneath these membranous patches was somewhat rough. Upon the inner and posterior wall of the cyst a groove could be distinctly traced from left to right which, at its left extremity, terminated in a canal, the size of a crow's quill, perforating the cyst wall. On tracing this canal beyond the wall of the sac it was found to dilate, its lining being white and smooth and, at some points, being thrown into transverse folds. The tail of the pancreas, which contained this duct, was indurated and sclerosed, containing no well marked acini, but it had retained its glandular structure. The terminal blind end of the duct, much dilated, was surrounded by dense connective tissue. The length of the duct from the sac to its termination measured two inches. The right extremity of the groove terminated in a second opening, through which a probe three mm. in diameter could be passed directly into the common duct in the head of the pancreas, after passing the concretion which filled the duct. Between the tail and head of the pancreas the glandular tissue had entirely disappeared, and its space, to the extent of two and a half inches, was taken up by the posterior wall of the cyst, which rested directly against the soft tissues between it and the vertebral column. The large vessels behind the tumor were not adherent, and in nowise affected by the tumor. In his remarks on the origin of this cyst, the author expressed his belief that it was caused by dilatation of the ductus Wirsungianus from obstruction to the free outflow of the pancreatic secretion by the calculus. The lungs and intestines were the seat of extensive tubercular disease.

Remarks.—The specimen just described illustrates an important lesson in pathology, viz. that long continued obstruction will eventually result in total destruction of the anatomical structure, and physiological function of the organ or part of organ beyond the point of obstruction. This fact has a direct practical bearing on the question of treating a cyst of the pancreas by the formation of a pancreatic fistula. The definitive closure of the fistula would be prevented if the distal portion of the gland tissue remained intact and the obstruction to its outflow remained permanent. Clinical experience and pathological specimens, however tend to prove that the enormous distension and pressure produced by these cysts, as well as the etiological conditions which produce them, result in almost complete destruction of the secreting structure in the immediate vicinity of the cysts, and the distal portion of the gland, which is equivalent to cessation of the secretory function of that portion of the organ.

---

[1] Auserlesene pathologische-anatomisch Beobachtungen. Virchow's Archiv, vol. [illegible], p. 360.

The second specimen described by von Recklinghausen was obtained from a male, aged 26 years who also died of diabetes. The lungs, pleura, and intestinal canal revealed the presence of tubercular lesions. The pancreas had undergone fatty degeneration so that only its head contained remnants of healthy glandular tissue. The common duct in the head of the organ was found dilated, and presented a varicose appearance. It contained a tenacious whitish fluid in which were suspended small calculous fragments composed of carbonate and phosphate of lime. In addition the duct contained two calculi, of which one measured one inch in length and three eighths of an inch in thickness, the second, still larger in size was one and one third of an inch long and of the same thickness. Both of these stones presented depressions and elevations on their surfaces which corresponded to the irregularities of that portion of the duct in which they were lodged. The common duct in the body and tail of the organ was dilated, its walls much thickened. The same changes were observed in the accessory ducts which could be traced through the fatty tissue, where they were seen to terminate in white strings of connective tissue. The distal ends of the small ducts contained mucus and fine calculous concretions.

Remarks.—In this instance, the dilatation of the duct did not proceed to any great extent, on account of the fatty degeneration of the organ, which probably occurred *pari passu* with the formation of the cause of obstruction, consequently the physiological activity of the gland was abolished, and no pancreatic juice was secreted behind the seat of impaction. The presence of the adipose tissue which preserved the shape and size of the organ is attributed by the author to a hypertrophy of the interstitial and adipose tissue rather than to a fatty degeneration of the secretory elements of the gland.

ABSTRACT OF THE ADDRESS OF SAMUEL K. JACKSON, M. D., NORFOLK, VA.,

PRESIDENT OF THE VIRGINIA STATE MEDICAL SOCIETY.

Delivered Wednesday Morning, Sept. 16th, 1885.

Among the hindrances to a more rapid march was the need of instruments of precision to assist our imperfect senses, and their subsequent invention gave a great impulse to medicine. Another of the hindrances to a more rapid growth, is a want, on the part of practitioners of a confidence in their resources, a hankering after novelties, and a too great credulity in the vaunted claims of medicines, and more particularly of combinations of therapeutical agents. They are too apt to allow enterprising pharmacists to do their thinking for them. Without clinical experience, how could they become good advisers as to the employment of therapeutical agents? and what is their testimony worth? The French courts have recently decided that no compound medicines can be sold except by those holding diplomas.

Among the errors of the times is the abandoning of the settled principles of medicine, principles which were the deductions of sound philosophy. An instance of this is the disregard of the principle that "local bleeding should never be practiced unless general blood letting had preceded it." This sound philosophical principle is well illustrated in the water-room, which is a somewhat recent invention. If a full current of blood is directed to one part of the body and suddenly arrested, serious consequences must ensue from the suddenly checked momentum.

The new treatment of pure inflammatory or fibrinous pneumonia he regarded an error which had been brought about by its being required in croupous pneumonia, when the sthenic form of the disease requires an entirely different mode. The two forms must be distinguished to ensure success in the treatment.

Another popular error is the use of cold baths for diminishing temperature, means as unphilosophical and irrational as to attempt to cool your stove by pouring water over it. The reasons for this view have been recently given in the *Physician's Magazine*, August, 1885. But a still greater error is the use of cardiac sedatives in inflammatory diseases. The advocates for their use forget the increase of fibrine during these diseases as well as the fibrinous deposits in the capillaries which the heart is struggling to remove. It is better to dissolve the fibrine and thus remove the obstruction, for then the heart soon becomes quieted, or if it is not you may then use your sedatives.

The absurdity of the two last mentioned class of remedies is well illustrated by supposing a man pumping hot water, holding in suspension melted wax or tallow, up into a reservoir. If his pipes become chilled the wax congeals, and he must work the harder. If he chills them further he increases the difficulty, and if he pump less energetically his conduits become so clogged as to prevent his working at all. Among the retarding influences to medicine were the want of the right men and the want of proper training. But there is an improvement in these respects brought about in great measure by the pressure brought to bear on schools, and by the publication of examination papers of candidates who had been graduated at some of our best schools. All of us have seen instances of such ignorance, and it has been difficult for us to understand how such could obtain diplomas. If such ignoramuses could elude sage professors, it is not to be wondered at that the people, unlearned in medicine, should consider them "*smart doctors*"

He briefly referred to medical education, and to the efficient State Board of Health of Virginia For want of time he was obliged to pass by the consideration of the factors in the recent high development of medicine, but he felt that he must acknowledge the valuable work contributed by the specialists However injurious to themselves in making them one sided men, it must be acknowledged that they have been of service to the profession

Our legislature should be petitioned to remove the license tax on physicians, which ought not to be imposed, because the most prominent work of the profession, at least at this day, is in the direction of preventive medicine The more disease we prevent the less we have to treat, and therefore the less compensation we receive *We are made to pay for thus benefitting the community in which we live* Virginia is one of the few, if not the only, States that taxes physicians

He urged upon the Society to do more original work, and upon the schools of the State to inspire their students with a love for original investigation, and instruct them in its methods

He suggested as an interesting and important subject of investigation, ' The Antagonisms of Germs," as he had no doubt that before very long they would be made use of for the cure of zymotic diseases We know of a few of these antagonisms, and we may reason from these that there are many others which probably we may take advantage of as therapeutic means We know that there is an antagonism between the malarial and typhoid fever poison Long before the use of modern antiseptic, *e g*, carbolic acid, etc, we were in the habit of using yeast poultices for ill conditioned ulcers, though we did not know it, we were making use of the antagonism between the torula cerevisiae and the pyogenic organism of the ulcer, and with an effect that compares most favorably with the modern means Erysipelas has lately been shown to be somewhat antidotal to cancer Ergot is said to be a prophylactic to puerperal fever, and an effectual remedy in whooping cough The use of the decoction of jequirity in pannus and granulated lid is another instance of these antagonisms When in after years these antagonisms shall be made use of therapeutically, for the cure of zymotic diseases, it may be a gratification to the then living members of this Society to remember that the suggestion was first made on this floor [1]

He urged the schools to give the proper training for this work, to educate the senses and the faculties needed for it, particularly the color sense, and faculty of appreciating and distinguishing form

He concluded by making the following suggestions 1st As to our inter State relations, proposing a plan for inter State representation 2d Proposing sanitary conventions, to interest and instruct the different communities in sanitary subjects and measures 3d On the commitment of the insane 4th Bringing to the attention of the proper departments of the government the fact that the Surgeons of the Army, Navy, and Marine Hospital Service sometimes set themselves in competition with the local physicians where they may be stationed, with a view of preventing this outrage 5th Arrangements for the collective investigation of disease 6th To interest the Society in the Rush monument 7th To attempt to secure representation of the profession in the State Legislature

---

MEDICAL PROGRESS

MATERIA MEDICA AND THERAPEUTICS

COMPOUND TINCTURE OF BENZOIN —Under the heading of "Friar's Balsam," DR TITUS DEVILLE, in a paper read before the Harrogate Medical Society, February, 1885, and given in full in the pages of the *Provincial Medical Journal*, July 1, 1885, gives a very interesting account of this drug and its usefulness in medicine This appears to be the only known medicinal preparation which has been perpetuated in its original form from the earliest ages of Christianity, and has maintained its high repute even to our own times in many civilized countries Its principal constituents form the incense powder which was employed in the ceremonies under the Mosaic dispensation, and perpetuated by the early Christian Church in its ritual, and is still found in daily use as a sacred emblem in most of the rites of the Universal Church In remote centuries, from the monasteries the hospital first sprang into existence The monks cultivated the art of medicine and surgery, and the wounded resorted thither to obtain the benefit of the skill of the brotherhood, and as an application ready at hand, a spirituous or vinous solution of incense powder most frequently produced a salutary influence, heightened first by the confidence of the donor in its special virtues, by the fact of the powder having been blessed and consecrated to holy purposes, and, secondly, being received by the sufferer with a lively faith in its wonderful efficacy. One of the synonyms of the Baume des Frères, frequently employed by ancient writers, is "Incense Balsam," and amongst other names by which the compound tincture of benzoin is known may be cited "Compound Tincture of Benjamin," "Jesuits' Drops," " The Commander's Balsam," "Wound Balsam," and ' L'Alcoolat Vulneraire "

Dr Deville considers its antiseptic virtues, its astringent and stimulating properties, and its therapeutical value externally when applied to wounds or diseases of the skin, abrasions, etc, internally in various fluxes and disorders of the mucous tract As to its antiseptic virtues he summarizes as follows

1 It coagulates albumen—(*a*) of the blood, (*b*) synovial fluid of tendinous sheaths and articulations, (*c*) albumen serum which bathes the meshes of areolar tissue, (*d*) the albuminous fluid which moist-

---

[1] Since the above was written the journals contain a notice of Prof Cantani of Naples using the bacteria of putrefaction (bacterium termo) for the destruction of the bacillus tuberculosis and give to him the credit of first suggesting the use of these antagonisms in a paper dated July 1885 whereas the President claimed that he had suggested it two years before at the meeting of the Virginia State Society at Rockbridge Alum Springs on Sept 6 1883

ens the surface of serous membranes of splanchnic cavities

2 When applied to the surface of wounds it coagulates immediately the albumen, which forms a grayish-white layer This coagulum is pure albumen

3 It provokes no inflammatory action or irritation

4 It arrests the bleeding of small vessels

5 It favors union by first intention, by producing an immediate coagulation at the surface of wounds, and by accelerating the plastic secretion

6 It prevents diffusive phlegmon (cellular cutaneous) by coagulating the albumen of aureolar tissue, which becomes at once dense and impermeable to any noxious liquids bathing the surface of the wounds

7 It prevents the propagation along tendinous sheaths of prurulent fluids by coagulating instantly the albumen of the synovia, and causing the surfaces of the sheaths in contact to become adherent, rendering them impermeable to liquids bathing the surface of recent wounds, and favoring adhesive inflammation of the synovial sheaths in the vicinity of the wound

8 It prevents purulent *infection by coagulating* the blood in the open veins at the surface of wounds, and in consequence of the instantaneous obstruction favors a prompt local adhesive phlebitis

With regard to its stimulant and astringent qualities, in acute inflammations its exhibition internally requires caution It is useful in many internal disorders, especially in constitutions and diseases attended with marked debility, in all asthenic fluxes, but is contraindicated in cases of great gastric irritation, or, having sthenic phases Applied to recent wounds it causes pain, and is frequently an irritant to such an extent as to impair and somewhat endanger union by first intention But when the edges of a wound have been carefully brought together and maintained by unirritating methods, then a solution composed of equal parts of Friar's balsam, collodion, and glycerine, with tannic acid, to brush over the intervening exposed parts of the wound, acts mechanically by forming a thin transparent pellicle, thus excluding the air, and keeping the parts in close apposition In threatened bed-sores, chronic inflammation of the flexures of the thighs and sides of the scrotum, vulva etc , it quickly induces healthy action It is a powerful stimulant when applied to foul and indolent ulcers and is an excellent preparation to apply to a carbuncle when the slough is separating Injected undiluted it decomposes fœtid secretions and establishes healthy action in these troublesome affections It is a valuable hæmastatic when applied to fresh wounds Dr Deville finds it very efficacious in chronic skin diseases of the scaly variety, when combined with vaseline, iodoform, zinc ointment, ungt hydrargyri nitratis, oleum cadeni, creosote, or petroleum He uses it mixed with equal parts of proof spirit or brandy, and injected into the uterine cavity, in severe cases of post partum hæmorrhage Alone or combined with equal parts of tannate of glycerine, it also has a wonderful efficacy in cases of abrasions of the mucous membrane, and slight ulcerations of the os uteri, applied on cotton wool It also proves very useful in gonorrhœa when combined with copaiba, oil of sandal-wood, and other preparations, after the acute stage has ceased He uses the following in chronic bronchitis by way of inhalation, where there is a profuse secretion and troublesome cough Creosote, tincture of conium and compound tincture of benzoin In phthisis, inhalations of carbolic acid, eucalyptol, tincture of conium, as adjuncts to the compound tincture of benzoin, one or more, as dictated by experience, frequently gives considerable relief In all asthenic fluxes, especially in internal hæmorrhage unconnected with piles, he combines this drug with the tincture laricis and liq opii sed

Papainized Milk—Dr Sidney Martin in a report on *the "Action of Papain," gives the following* practical suggestions regarding the preparation of papainized milk

A pint of milk is taken, and a quarter of a pint of water, add an equal volume of milk to the water, and 30 grains of bicarbonate of soda, and boil, add the remaining milk to the hot liquid The resulting temperature varies from 45° to 55° Cent , it is usually about 48° Cent (118° Fahr), the variation depends, of course, on the temperature of the cold milk The papain must now be quickly stirred in, and the mixture covered with a cosey, and placed in a warm place After digestion, it is boiled, to stop the action This method does as well for pancreatic as for papain digestion, it obviates the use of a thermometer, and so can readily be done in the ward or sick room

For preparing a partly digested milk, seven grains of papain, with an hour and a half's digestion, is quite sufficient, using a pint of milk in the manner above described, for the more complete digestion, 10 grains for two hours must be used

The food is greedily taken by kittens, but he has not yet tried it on patients —*British Medical Journal*, July 25 1885

Tincture of Iodine in Diphtheria —Dr Edward Adamson (*Practitioner*, July, 1885), has found iodine, taken internally in a liquid form, as the tincture may be thoroughly relied upon, in order to promote the separation of exudative membranes, to check the formation of new exudations, to lessen the secretion of viscid offensive saliva, to destroy the vile factor of the breath, and, in fact, generally to correct the morbid condition of the fauces, tonsils, etc Within thirty-six hours a marked improvement *in every respect* is noticeable, which is generally perceptible even to the patient, so that there is often an eager desire to accelerate the frequency of the doses of the iodine Out of fifty-five cases of diphtheria thus treated with tincture of iodine alone—and some very grave cases indeed—fifty three recovered without any troublesome sequelæ whatever The doses for adults were five to seven minims every hour, or every two hours, according to circumstances, and for children of six years to twelve years, *two to three* minims taken every two hours in syrupous aurantii ℥iij and water, or in some other neutral syrup

MEDICINE

A Test for Hearing.—Dr. Jos. Gruber (*Monat. fur Ohrenheilkunde*), referring to Rinne's experiment as to the comparative facility in the conduction of sound through the air and through bone under normal conditions, and to his statement that the sound of the tuning-fork is heard at the meatus after it has ceased to vibrate on the vertex, suggests the following experiment as an additional test of hearing. When the tuning fork (held before the ear according to Rinne's experiment) has become inaudible, place one finger upon the meatus of the ear to be examined, in such a way that the finger loosely closes the passage. Now place the tuning fork against the finger closing the ear, and the sound is again heard, and continues for a longer or shorter time. When the tuning fork has ceased to vibrate on the finger, it is again heard through the air, the stronger in proportion to its nearness to the meatus. Gruber explains this on the ground that the sound from the tuning-fork touching the finger in contact with the walls of the external auditory meatus is conducted to the labyrinth better than by contact with any other portion of the skull, such as the teeth. Gruber thinks that this method will be of service in detecting cases of one sided simulated deafness.—*Medical Chronicle*, July, 1885.

Chloroma.—Since Balfour in 1834 described chloroma, ten cases have found a place in medical literature, though of these one is somewhat doubtful, and may have been anæmia or pernicious anæmia. An eleventh case has lately been observed by Gade in Christiana. The subject was, as is invariably the case, a child, a little girl of five years. The first symptoms were deficiency of blood, a tumor of the left cheek, toothache, otorrhœa, singing in the ear, deafness, and exophthalmus, which gradually increased. Afterwards fever and extreme prostration supervened, and she died in about two months. At the autopsy, numerous yellowish green tumors of fibro sarcomatous structure were found in many different parts of the body, more particularly on the periosteum. They were found also on the dura mater, in the liver, colon, lateral ligaments, and kidney, and even in the marrow of the long bones. On the legs a number of dark spots were seen, some of which contained a soft greasy substance. The origin of the greenish coloring matter was thought by Otto, and Gade agrees with him, to be in the fat granules, numbers of these being found in the cells, and so to be independent of both bile coloring matter and hæmatin.—*Lancet*, July 11, 1885.

Tabes Dorsalis in Women.—Mobius has described thirteen cases of tabes in women, making, with cases already published, altogether eighteen, in which special attention was directed to any syphilitic taint which might be present. It will be remembered that the opponents of the theory of the syphilitic origin of locomotor ataxy lay stress on the circumstance that, when tabes occurs in women no specific history or symptoms are found, and that the disease is therefore owing to entirely different causes, such as the influence of cold, damp, etc. Mobius, however, has by careful examination succeeded in eliciting a syphilitic history in all but two of his female cases. This must be, in the nature of things, a point of great difficulty, and one which it is only too easy to overlook in examining a case, unless specially inquired into. If we consider, in addition to this, how eager women are to deny that they ever had such a disease, it will be acknowledged that some positive evidence is of more importance than numerous negative statements. Moreover, the immediate consequences of infection are often in women so exceedingly obscure, that they are themselves unaware of being infected, and mild forms of primary and secondary syphilis are known to lead more commonly to tabes in after life than severe manifestations. Mobius has found that the age of these women was between 21 and 43, the same as in men, where the disease habitually occurs in the prime of life. All had had sexual intercourse, tabes has never been observed in a virgin, nor in women whose character or habits of life rendered infection unlikely. None of the patients had had suspicious discharges, buboes, miscarriages, baldness, ulcerated throat, and cutaneous affections. It is known that women who have had connection with syphilitic men, and given birth to syphilitic children, may never have shown signs of syphilis themselves, and yet have undergone a change in their constitution, in so far as they have acquired an immunity against primary infection. Some authors call this syphilization, and look upon it as a sort of inoculation. Such syphilization may possibly be sufficient for the causation of tabes. None of the women examined by Mobius had any symptoms of syphilis at the time, except slight enlargement of lymphatic glands and old cicatrices, showing that the affection had been mild. The interval between infection and the beginning of tabes was on the average seven years, the shortest being four, and the longest fifteen years. Several of these patients had given birth to healthy children, either in the interval, or after the outbreak of tabes. As far as exciting causes were concerned, the puerperal state appeared to have been frequently instrumental in accelerating the evolution of tabes, the debility caused by profuse hæmorrhage aggravating the condition in one case. The influence of cold was also mentioned in several cases, depressing emotions and the neurotic constitution appeared to be less effective. In a number of cases, however, no exciting causes whatever could be determined.—*Centralbl. fur Nervenheilkunde*, Oct. 15, 1884, *Practitioner*, July, 1885.

SURGERY

Ligations of the Arteries of the Palm of the Hand and Sole of the Foot.—Ed. Delorme has recently published a very valuable memoir on this subject, illustrated by a large number of plates, and supplemented by a number of dried preparations, among them over two hundred hands, which are deposited in the museum at Val-de-Grace. His methods are as follows:

1. *Ligature of the Radio palmar.*—Make an incision slightly convex from the scaphoid tubercle a lit-

tle outwards, 0 m, 05 centimètres in length to the second interdigital space

2 *Ligature of the Direct Cubital (superficial arch)* Trace the line of Boeckel and incise externally to the pisiform bone, following a line to the third interdigital space and line of Boeckel

3 *Ligature of the Transverse Portion* —Extend the incision of Boeckel 5 to 8 millimetres

4 *Ligature of the Trunk of the Collaterals of the Thumb* —Follow on the back of the hand the internal border of the first metacarpal The artery is between the first dorsal interosseous and the adductor pollicis

5 *Ligature of the Trunk of the Index Collateral* — Incise the length of the internal border of the second metacarpal, remove the first dorsal interosseous, the artery is under its aponeurosis

6 *Ligature of the Radial Origin of the Deep Arch* Same incision, pass to the tubercle of the second metacarpal and then inwards to the anterior surface of the bone, where will be found the origin of the deep arch

7 *External Palmar Incision* —Incise on a line passing from the interval of the eminences and to the external border of the index Cut deeply to the external border of the first of the lumbricales, the artery will be found in the insertions of the adductor pollicis

8 *Median Palmar Incision* —Incise on a line which prolongs the axis of the index to the middle of the hand, there find the external border of the lumbrical of the medius, flex the hand and the artery will be found at the superior portion near the base of the third metacarpal, crossed by the ulnar nerve

9 *Internal Palmar Incision*—Passing between the hypothenar eminence and the flexors, let the incision follow a line from the interval of the eminences near to the fold of the little finger Seek the interval between the flexor minimi digiti and the mass of the hypothenar muscles, flex the fingers, and the artery is under the aponeurosis, it crosses the tendon

In his study of the foot Delorme has deposited in the museum more than fifty injected feet to prove his dissections He considers

1 *Internal Plantar* (at its origin) The incision passes from the scaphoid tubercle to the tubercle of the small apophysis of the calcaneum Cut through the skin and aponeurosis and draw aside the fibres of the adductor pollicis

2 *External Plantar* —Same incision, the probe following the direction of the artery which may pass for 7 centimetres from its origin

3 *External Plantar* (calcanean portion) Trace across the heel a line prolonged in the direction of the internal malleolus A little below it, some 8 centimètres, incise a line which shall pass from a quarter of the internal heel to the first interdigital space Under the aponeurosis, disengage the internal border of the short flexor on the plantar surface of the accessory appears the nerve, and the artery is external to it

4 *External Plantar* (calcaneo culoid portion) Incise below the transverse line of the heel, following a line passing from the middle of the heel to the space which separates the third and fourth metatarsals Beneath the aponeurosis, disengage the external border of the short flexor, the artery is applied to the superficial surface of the accessory with the nerve and veins

5 *Ligature of the Arch* —Antero external plantar incision —Incision of 8 centimetres at the crossing of the lines going from the tubercle of the fifth metatarsal to the internal sesamoid bone of the first, and from the crease of the fourth with the fifth in the middle of the heel Pass a little within this last line and parallel to it Seek the external border of the adductor obliqus, the artery is at its superior insertion, covered by the interosseous aponeurosis The nerve conceals the vessel on the third metatarsal

6 *Ligature of the External Plantar at its Termination* —Antero internal incision Trace a line perpendicular to the axis of the foot, one centimètre in front of the internal tubercle of the first metatarsal, a second line directed from the first interdigital space to the internal quarter of the heel, at the junction of these two lines, a little externally on the second, and for about 8 centimètres, make the incision, the short flexor and the internal plantar nerve will be recognized Penetrate between the short flexor and the oblique adductor, feel the tubercle of insertion of the long lateral peroneal The artery will be found some millimetres below and a centimetre in depth on the second metatarsal —*Archives Med Belg*, May, 1885

VARICOCELE TREATED BY THE SUBCUTANEOUS WIRE LOOP —MR R BARWELL, in the *Lancet*, May, 1885, gives an abstract of 100 cases of varicocele treated by the subcutaneous wire loop In none of these did the operation produce bleeding, shivering, pyrexia, or erysipelas The wire takes from eight to sixteen days before it comes away The operation is almost painless, except at the moment of tightening the wires The results of this operation are extremely good, and it is an easy and safe method of procedure

OBSTETRICS AND GYNÆCOLOGY

EXTEMPORANEOUS EXAMINATION OF WOMAN'S MILK —DR HELOT, in the *Union Médicale de la Seine Inférieure*, recommends a simple method of determining the quality of human milk He undoubtedly accords superiority to chemical analysis, but as this process is so long and difficult, the common practice has been to rely upon the appearance of the milk Dr Helot's method consists in comparing the number of drops in a given volume of distilled water at 60° F with those of the same volume of milk Good milk, such as produces a mean increase of an ounce per day in the child's weight, gives thirty five drops in the same volume which, of water, gives but thirty If the milk be of superior quality the volume may yield as high as thirty eight drops If on the contrary but thirty three or less are obtained, the milk should be mistrusted Both breasts should be examined while the nursing is going on —*Medical Record*, August 15, 1885

THE
Journal of the American Medical Association
PUBLISHED WEEKLY.

THE EDITOR of this JOURNAL would be glad to receive any items of general interest in regard to local events or matters that it is desirable to call to the attention of the profession. Letters written for publication or containing items of information should be accompanied by the writer's full name and address, although not necessarily to be published. All communications in regard to editorial work should be addressed to the Editor.

SUBSCRIPTION PRICE, INCLUDING POSTAGE.
PER ANNUM, IN ADVANCE $5.00
SINGLE COPIES 10 CENTS.

Subscriptions may begin at any time. The safest mode of remittance is by bank check or postal money order, drawn to the order of the undersigned. When neither is accessible, remittances may be made at the risk of the publishers, by forwarding in REGISTERED letters.

Address,
JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION,
No. 65 RANDOLPH STREET,
CHICAGO, ILLINOIS.

SATURDAY, OCTOBER 3, 1885.

THE EXECUTIVE COMMITTEE OF THE NINTH INTERNATIONAL MEDICAL CONGRESS.

The first meeting of this Committee, consisting of the General Officers of the Preliminary Organization of the Congress and the Presidents of the Sections, was held in New York, September 24, 1885. More than a quorum of the members of the Committee were present, consisting of the President, Prof. Austin Flint; Treasurer, E. S. F. Arnold, M.D., M.R.C.S.; Chairman of the Finance Committee, Prof. Frederick S. Dennis; President of the Section of General Medicine, Prof. Abram B. Arnold; President of the Section of General Surgery, Prof. Wm. T. Briggs; President of the Section of Military and Naval Medicine and Surgery, Prof. Henry H. Smith; President of the Section of Diseases of Children, Prof. J. Lewis Smith; President of the Section of Anatomy, Prof. Wm. H. Pancoast; President of the Section of Collective Investigation, Vital Statistics and Climatology, Henry O. Marcy, A.M., M.D.; President of the Section of Dermatology and Syphilis, Prof. A. R. Robinson.

The Committee was organized by the election of Henry H. Smith, of Philadelphia, as Chairman, and F. S. Dennis, of New York, as Secretary *pro tem.* After a free interchange of views, Prof. Frederick S. Dennis was appointed Associate Secretary-General, and another appointed to the chairmanship of the Finance Committee. The President, the Secretary-General, and the Associate Secretary-General were instructed to issue a circular announcing the Preliminary Organization of the Congress and the rules adopted for its membership and government. To prevent all further misunderstanding, both at home and abroad, the Committee unanimously adopted the following resolution:

Resolved, That this Executive Committee enters upon the management of the affairs of the Ninth International Medical Congress, with the understanding that, in accordance with Rule No. 10, its powers are not restricted except by the rules and regulations adopted Sept. 3, 1885, by the Committee of Arrangements appointed by the American Medical Association in April, 1885, and that the actions of this Executive Committee, are final, not being subject to revision, amendment or alteration by either the Committee of Arrangements or the American Medical Association.

The Rule 10, alluded to in this resolution, is as follows:

"10. The President of the Congress, the Secretary-General, the Treasurer, the Chairman of the Finance Committee, and the Presidents of the Sections, shall together constitute an Executive Committee of the Congress, which Committee shall direct the business of the Congress, shall authorize all expenditures for the immediate purposes of the Congress, shall supervise and audit the accounts of the Treasurer, and shall fill all vacancies in the offices of the Congress and of the Sections. This Committee shall have power to add to its membership, but the total number of members shall not exceed thirty. A number equal to one third of the members of the Committee shall constitute a quorum for the transaction of business."

The proceedings of the Committee were characterized by entire harmony and a commendable zeal in pushing forward the proper preparations for the Congress.

ASPIRATION A CAUSE OF THE SPREAD OF TUBERCULOSIS WITHIN THE LUNGS.

In the *Zeitschrift für Klinische Medicin*, vol. 3, PROFESSOR LEYDEN, of Berlin, publishes an article entitled "Klinisches uber den Tuberkel-Bacillus," wherein he announces very decidedly his belief in the possibility of auto infection in tuberculosis. He states that the extension of tuberculosis within the lungs takes place in the later stages of the disease, when, owing to the weakened state of the organism, the ability to expectorate becomes inadequate to expel the offending secretion. The ineffectual efforts, that are made to cough, only result in dislodging the stagnant material, which, during each act of forced inspiration, is driven by a process of aspiration into more distant parts. The alveoli, thus invaded by a substance rich in bacilli, furnish a fresh starting-point for the disease. This proposition, which is not new, is yet worthy of thoughtful consideration. It will be observed that Leyden limits this occurrence to the later stages of consumption, but in a contribution to the *Berliner Klinische Wochenschrift*, vol 31, Dr Von Brunn, of San Remo, makes some further suggestions which appear to us to be worthy of presentation to the readers of the JOURNAL

DR VON BRUNN not only heartily endorses Leyden's proposition, but thinks that under favorable conditions tuberculosis may be spread within the lungs by aspiration even during the earlier stages These conditions are furnished when the larynx, as well as the lungs, is involved If, as is not unfrequent, the epiglottis and contiguous tissues become inflamed and ulcerated the act of deglutition is rendered extremely painful and almost impossible of performance But a small amount of food, and that chiefly fluid, is injested, and consequently the nutrition of the body suffers Hectic fever, with its attendant symptoms develops, and the disease assumes the florid type This is the explanation generally accepted by the practitioner Dr Von Brunn however, would add another factor to that of inanition, viz In consequence of the partial erosion of the epiglottis, or of its inability for other reasons to adequately occlude the rhyma glottidis, particles of food frequently make their way into the chink of the glottis Their presence here at once excites cough, which, however, is preceded by a forced inspiration Hence, not only the offending fragment of food is drawn by aspiration into the bronchial tubes, but along with it goes some of the laryngeal or bronchial secretion with its cargo of bacilli If, now, the epiglottis can not accurately close the larynx, or, if the patient's strength be deficient, the explosive effort of the cough is inadequate to remove the offending material which becomes lodged in peripheral alveoli A circumscribed patch of lobular pneumonia is the result perchance, which, to use Dr Von Brunn's words, furnishes excellent ground for the growth of bacilli

Von Brunn was long ago led to infer this possibility from the observation, that in cases of laryngeal phthisis, the pulmonary affection advances coincidently with the appearance of multiple zones of inflammatory infiltration within the lungs What was previously but an inference has recently been verified into a conviction by the following case

Herr L thirty five years of age, of a healthy family, has suffered with tubercular deposit in the upper lobe of his right lung Nevertheless the constitutional disturbance remained slight until November of last year He then lost appetite strength and desire for work, and, as his larynx appeared to be free from disease he was sent to Davos, Switzerland The high mountainous climate soon restored his general health, but exercised a deleterious influence upon his larynx Hoarseness increased to aphonia, and he was annoyed by pain, a constant feeling of dryness of the throat and occasional attacks of difficulty of deglutition Accordingly he removed to San Remo in February last, and came under the care of Dr Von Brunn His general condition was encouraging A laryngoscopical examination, however, revealed inflammatory swelling of the epiglottis, an ulcer the size of a three cent piece upon the left glosso epiglottidian fold, erosion of the posterior surface of the arytenoid cartilage, swelling of both vocal chords, with deep ulceration of the posterior third of the left one Physical examination discovered some consolidation of the apex of the right lung, with occasional dry râles A microscopic examination of the sputa and of the secretion of the larynx disclosed the presence of numerous bacilli Notwithstanding his difficulty in swallowing, the patient was able to consume sufficient nourishment for the maintenance of his general health The twentieth of last March, while at breakfast, a fragment of food escaped into the glottis, and set up a violent paroxysm of coughing with convulsive inspiratory movements A few hours subsequently the man was seized with a chill, followed by an elevation of temperature to 104° F Upon percussion the Doctor found a patch of lobular pneumonia the size of an apple, and situated just below the left scapula, at a point which but the day previous, had yielded perfectly normal resonance Ten days later the same thing was repeated, a violent fit of coughing while partaking of food, and the repetition a few hours thereafter of chill and fever This time the Doctor outlined a circumscribed area of dulness in the left axillary region Von Brunn very reasonably thinks the causal relation of the cough to the development of the acute lobular pneumonia suggests itself The particle of food, that together with tubercular products, rich in bacilli, had been swept by aspiration into the peripheral alveoli, acted as a local irritant, and thus set up a pneumonic process of limited extent, which, in the Doctor's opinion, would afford an excellent *nidus* for the maintenance of the tubercular bacilli in full activity In order to obviate any further accidents of a similar kind, insufflations were employed of cocaine and morphine, as recommended by Schnitzler, fifteen minutes before every meal, apparently with most favorable results

This case is a suggestive one, to say the least Whether one be inclined to agree with the implied belief that the bacilli contained in the secretion constitute the *materia morbosa*, or not, he must recognize the danger of extension of the disease, which lurks behind the inflammatory process, as well as the immediate danger involved in the acute pneumonia. It suggests also the importance of a careful preventive treatment.

FUNCTIONAL TROUBLES DEPENDENT ON NEURASTHENIA.

In a paper read at the recent annual meeting of the British Medical Association, and published in the *British Medical Journal* of September 5, DR. J. STRAHAN calls attention to what he calls some "Puzzling Conditions of the Heart and other Organs dependent on Neurasthenia." In view of the comparative frequency of these conditions—being much more common than is generally supposed—the fact that they are sometimes only recognized with difficulty and in many cases not at all, and that the subject is untouched in medical literature save by a very limited number of authors, Dr. Strahan's paper is very timely.

These conditions, or symptoms as they may be called, are veritable diagnostic stumbling blocks when occurring as purely neurasthenic phenomena, since they often point to seemingly serious organic troubles. Dr. Strahan defines neurasthenia as "a condition of prostration of the whole or some part of the nervous centres, owing to deficient nutrition, in which there is no gross lesion, visible to the eye or to the microscope, of any part of the brain or spinal cord." He expresses the opinion that such cases as the so called spermatorrhœa, chloralism, bromism, alcoholism, meconism (opio mania), caffeinism, and the nerve-prostration due to many such drugs, are examples of general neurasthenia, in so far as the purely nervous symptoms, and not the material lesions caused, are concerned.

The chief functional troubles occurring in neurasthenia are those of the heart and vascular system and of the brain—and, it may be added, purely neurasthenic phenomena in women, either simulating or leading to a diagnosis of uterine disease, as was pointed out by Professor Goodell some time since, in a lecture in which he insisted that a great medical error of the day is the mistaking of nerve disease for uterine disease. So frequent is this error that many, even very eminent specialists, seem to regard the uterus as an anatomico pathological Mecca to which every symptom or condition in woman points as a sign post. But though these puzzling conditions of which Dr. Strahan speaks are usually symptoms pointing to cardiac or cerebral trouble, we cannot draw hard and fast lines, and distinguish one case as a purely cardiac neurasthenia, and another one as cerebral neurasthenia (or uterine neurasthenia). In the case of a male the cardiac and vascular phenomena are always attended by cerebral symptoms, and the cardiac and cerebral conditions are usually attendant on the supposed uterine symptoms in the female. There can be but little doubt, however, that cases of pure neurasthenia are much more frequent in males than in females, and certainly the affection—if it may be so called—is far more frequent among professional men. Indeed, one in every ten of the patients is said to be a medical man.

Prominent among the vascular phenomena in neurasthenia is visible pulsation of the arteries, when functional. As Dr. Strahan well points out, the Corrigan or water-hammer pulse is by no means a pathognomonic symptom of aortic insufficiency, as it also occurs in fibroid degeneration of the arteries, great arterial relaxation, and in high arterial tension. All are familiar with the fact that excitement will often cause visible carotid pulsation, especially in nervous women, and we also know that in pericarditis accompanied by carditis or pericardial effusion, which are usually associated with arterial relaxation, visible pulsation is common and well marked. Dr. Strahan points out a valuable diagnostic difference in these cases, in aortic regurgitation the carotid pulsation extends to the lobe of the ear, and perhaps to the facial and temporal arteries, while in purely nervous cases it extends only half-way up the neck. But though visible pulsation with very tortuous arteries points more to fibroid degeneration, tortuosity may be caused by high tension without degeneration; though it does not appear in the high tension due to Bright's disease, nor in that of diabetes. The complex nervous supply of the heart is sufficient explanation of the susceptibility of that organ to changes in nervous force, and we could not expect otherwise than that the heart should be disordered in neurasthenia, since it is easily influenced by an uncontrolled emotion, any reflex irritation from the brain, alimentary canal, or prostatic urethra.

Insomnia is a prominent neurasthenic condition of functional cerebral disorder, and its susceptibility to treatment is an excellent criterion of improvement of the neurasthenic condition. The insomnia of neurasthenia seems to be characterized by a markedly varied and dissonant activity of the brain, and by a variety of spasmodic movements of the limbs when the person is on the point of falling asleep, and during the normal waking hours the patient finds it impossible to concentrate the mind on any subject. In this connection, also, may be mentioned the morbid fears, and a peculiar and almost characteristic inability to look others in the face In the larger number of cases these fears are seen in male cases, and are usually the result of sexual exhaustion "Pain and weight at the vertex of the head (supposed to be distinctive of cerebral anæmia) are usually neurasthenic They may depend on cerebral anæmia immediately, but, if so, the anæmia depends on neurasthenia acting through the vaso motor nerves" Tenderness of the scalp—another neurasthenic symptom—is to the exhausted brain what spinal irritation is to the exhausted cord It should be particularly borne in mind that neurasthenics are liable to accommodative or muscular asthenopia, and that glasses totally fail to give relief in these cases

Finally may be mentioned a form of dyspepsia frequently encountered in neurasthenic cases, which is peculiar in that the sufferings are always greatest when the stomach is empty The gastric distress and other symptoms pass off when food is taken The fact that arsenic gives the best results in these cases is sufficient evidence of their neurotic origin

THE MORAL SIDE OF EUTHANASIA

About a year ago, a paper on "Euthanasia" was read by Dr Henry Leffmann before the Medico legal Society of Philadelphia The author of the paper did not express any decided opinion for or against this rather euphemistic term for what may be called *professional murder*, the paper was read to provoke discussion rather than for the purpose of drawing any conclusions In the *Medical Record*, of September [illegible], is a leading editorial article on this subject, in which the writer seems to take the ground that professional opinion is not *yet* in so advanced a state as to decide the matter in all cases, that the practice would have to be under legal restraint, and that "the further settlement of this question depends on the growth of public opinion We cannot hasten it For the present, the guide of each man must be his own conscience"

Our contemporary does not discuss the moral aspect of this question Perhaps it may be said that the physician, in his professional capacity, has nothing to do with the moral side of such questions And though our contemporary does not thus commit himself the inference is certainly very clearly drawn and expressed in the last sentence quoted But where is the consistency of the man who can hold—as does every physician—that destruction of the ovum, after gestation has commenced, is murder, save when the life of the mother is at stake, who can preach this doctrine to an unfortunate patient, and then, perhaps within the hour, terminate even a certainly hopeless case by his own act? What has the consent of the patient to do with the right or wrong of this question? Who knows but that the patient may regret his choice when too late? What physician will pretend to be the judge as to the absolute certainty of death in one-half of the cases that seem running on to a fatal termination? It is said that the rigid enforcement of the principles of euthanasia "would not allow for possible errors in diagnosis In cases of carcinoma and phthisis no room for such doubt would exist" And in the same paragraph it is said "Patients supposed to be *in extremis* have often recovered" Have not most desperate cases of phthisis—patients that seemed *in articulo mortis*—revived, come back almost from the grave, and lived for months and sometimes for a year or more? So that even in phthisis there is room for doubt—and while there is doubt there is always hope

A member of the Birmingham (England?) Speculative Club has thus formulated the relation of euthanasia to the office of the physician "That in all cases of hopeless and painful illness, it should be the recognized duty of the medical attendant, whenever so desired by the patient, to administer chloroform or other anæsthetic, so as to destroy consciousness at once and put the sufferer to a quick and easy death, all needful precautions being adopted to prevent any possible abuse of such duty, and means being taken to establish beyond the possibility of a doubt that the remedy was applied at the express wish of the patient" In other words, the physician is to don the robes of an executioner, and apply what our speculative friend is pleased to term a *remedy* It is to be hoped that the promulgator of that *formula* is not a physician The idea itself is ghastly, and the principle would put into the hands of unscrupulous parties a certain and easy method of being rid of an objectionable relative—for, though every medical man should blush that it may be said, there are men in the profession who could be bought to sign a certificate behind which the law could not go Should any one be tempted to deny this, we need only refer to those London physicians who have reached such a depth of vice that they could sign away the virtue of young and innocent girls for a pecuniary consideration, and are we to believe that these men would hesitate to perform the functions of professional assassins for money?

Our contemporary says further "The mind of the laity, as well as of the profession, has already changed upon this matter, the assumption in such cases being—as in all matters concerning man's relation to the hereafter—toward a more liberal standpoint." A more *liberal* standpoint on a moral question means nothing more or less than a more lax state of morality. We do not need liberality of opinion on these questions. And even though every member of the Birmingham Club should endorse this horrible principle, though every physician should declare his willingness to be a scientific assassin in these cases, and though every legislative body in the world should elevate this principle to a legal standard, it would still remain, and always will be murder.

SOCIETY PROCEEDINGS.

MEDICAL SOCIETY OF VIRGINIA.

Sixteenth Annual Session held September 15, 16 and 17, 1885.

The Sixteenth Annual Session of the Medical Society of Virginia, convened at Alleghany Springs, Montgomery Co., Va., at 8 P. M., September 15th, 1885. Owing to a railroad accident, the President, Dr. S. K. Jackson, of Norfolk, did not arrive until the next day. Dr. Bedford Brown, of Alexandria, presided the first night. Some 150 or more doctors were in attendance during the session—the largest number ever present at any session—and were the guests of the attentive proprietor of this far famed Summer Health Resort, Col. C. A. Colhoun. Drs. Geo. T. Harrison, of New York City, an Honorary Member of the Society, Archer Atkinson, of Baltimore, J. S. Conrad, of Matley Hill, Md., Thos. Evans, of West Virginia, and Wm. G. Eggleston, of Chicago, Ill., were among the prominent visitors from other States. About 110 new members joined during the session, which lasted through the night session of September 17th, when a handsome entertainment in the form of a banquet and a ball was given by the popular host to all the guests—ladies and gentlemen.

Tuesday, Sept. 15.—Evening Session.

The Annual Address to the Public and Profession was delivered by Dr. H. M. Clarkson, Haymarket, Va., whose subject was

Medical Societies—Their Relations to the Public.

A large promiscuous audience, composed of the visitors at the Springs from all parts of the United States, as well as the doctors, were kept interested for over half an hour in this address, full of useful general information and suggestions.

Dr. Isaac White, of Shawsville, Resident Physician at Alleghany Springs, Va., read a paper on the

MEDICINAL PROPERTIES OF ALLEGHANY WATERS.

The geological formations in this section consist chiefly of magnesian limestone and argillaceous slates. Ores of iron, silver, lead and zinc are in the immediate vicinity. The water of the Springs has a temperature of 56° F., and the specific gravity is 1.00283, it has a saline taste, and a slightly acid reaction. In giving the analysis, he incidentally stated that the effects of baryta and strontia are somewhat like those of arsenic. He had not become such an enthusiast in reference to Alleghany water as to claim for it specific properties for every disease, but the range of its efficacy is distinct and extensive. He recommended the waters especially in dyspeptic cases, using the term "dyspeptic" in its generic sense. He believed the magnesian salts in this water are their great power. Frequently, when first taken, the water produces a strange feeling in the head, a giddiness, which is often closely followed by decided headache. Erythema and even eczema, and sometimes boils developed after using the water. A glassful, gradually increased to two glassfuls, may be taken before meals, but the dose must be changed according to the desire for a tonic, diuretic or cathartic effect.

Dr. Wm. C. Dabney, of Charlottesville, Va., as President, presented the

REPORT OF THE VIRGINIA STATE BOARD OF MEDICAL EXAMINERS,

showing the Board organized according to law in November, 1884. The State law requires that any person who undertakes to begin practice of medicine in Virginia since January, 1885, shall pass a satisfactory examination on the seven usual divisions of medical study before the Board—regardless of college diplomas. Up to this time thirty-two candidates have passed satisfactory examinations and been licensed to practice medicine in Virginia, six have been rejected. Every one of the applicants were college graduates. A penalty of $500 fine is imposed on any one who undertakes to practice in Virginia unless he had a license prior to January, 1885.

The Report of the Necrological Committee, presented by Dr. S. C. Gleaves, of Wytheville, Va., shows that, during the year just ended, 16 of the 430 members on adjournment of the last annual session, have died.

Wednesday, Sept. 16.—Morning Session.

Mr. J. W. Thomas, of Norfolk, Va., delegate from the Virginia Pharmaceutical Association, read a paper on the

RELATIONS OF PHYSICIAN AND PHARMACIST,

and exhibited a book of formulæ of standard proprietary preparations, which if adopted by the physicians of the State, would enable home apothecaries to prepare the elixirs, etc.

Dr. Sam'l K. Jackson, of Norfolk, delivered the

PRESIDENT'S ADDRESS,

an abstract of which will be found on page 374.

Dr. Thomas J. Moore, of Richmond, Va., opened the subject for general discussion by a full paper on

SCARLET FEVER.

He recognized the division of the fever generally adopted by American authors as the most practical under which the various types could be described, viz S simplex, S anginosa and S maligna He portrayed fully and with great minuteness the classical types of each, one of these forms being described with particular gracefulness—that of the malignant and irregular type, more completely in regard to prognosis, as the grouping of the various symptoms indicated, anticipative, immediate danger, or those where death was inevitable He traced the history of the disease from the time it was first defined by Sydenham, in 1661, down to the present day The etiology of the fever was extensively discussed, more particularly as to its origin The germ theory was fully entered into, from the time of Pasteur's first suggestions in 1861, down to the present Pollander, Brawell, Davainne, Rayer, Toussaint with Pasteur of France, Koch, Cohn, Virchow, Klebs, Obermeier, Bollinger, Nagle and others of Germany, Tommasi Crudeli of Italy, Burdon Saunderson, and Tyndal of England, were all referred to, and their merits as painstaking and ingenious investigators dwelt upon The success in cultivating and inoculating the special microbes of charbon, chicken cholera, murrain, and other diseases, in the lower animals, with modification of the symptoms, and abatement in the severity of the respective diseases, were described, and the hope expressed that corresponding advances in human *parasitology* may follow close in their wake He stated that up to this time the only germ which has filled all the necessary requirements, as found in man through inoculation and otherwise, is the spiro bacterium of relapsing fever found by Obermier and called after him

The parallelism between small pox and charbon was spoken of, travelling, however, in contrary directions, the one from man to the lower animals, the other from domestic animals to man, the special bacillus of the latter had been discovered through attenuation and inoculation it fulfilled all that the law required of it, like vaccination in small pox, it produced, through inoculation of a remote culture from the virus of the lower animals, immunity in the human family, the peculiar microbe producing the former has not yet been determined, he hoped it would come to light at a day not far distant Continuing, he said that there were two microbes described as giving rise to scarlatina—the *monas scarlatinosum* of Klebs, and the *plox scindens* of Eklund, of Stockholm—each one ingeniously put forward as the true bacillus Klebs does not indulge in the enthusiasm peculiar to confidence—Eklund endeavors to demonstrate the absolutism of his proposition

Dr Moore declared that he did not believe that the special microbe producing this disease had yet been recognized, and the question, to say the least of it, remained undetermined and open The part of the address devoted to treatment was long and exhaustive He carefully described the merits of belladonna—citing the opinions of the homœopathists who had introduced it as carrying out the very essence of their doctrine, with that of the regulars who had partially or completely accepted it He did not believe that the drug possesses prophylactic powers and declared its action indifferent when used to mitigate symptoms during the progress of the disease For the reduction of temperature he preferred the ice cap to the head, and rubber bags over the front of the neck and covering the great vessels (filled with ice or iced water), conjoined with sponging, failing in this he used wet sheets, then cold pack, and as a last resort, the cold bath as described by Ziemssen He never feared the depressing effects of cold water, as patients could always be relieved from impending congestion by free resort to alcoholic stimulation His favorite internal antipyretic up to this time was quinine, administered by rectum or hypodermically when the stomach was irritable He hoped much from resorcin, and urged his brethren to try it and give their clinical experience to the world, the drug was safe, certain in action, and a germ destroyer As an unguent, especially where itching and burning were prominent symptoms, he knew nothing equal to a combination of glycerine, boracic acid, and carbolic acid, in the proportion of one ounce, one dram, and fifteen minims, respectively, in the order named, both the borax and carbolic acid obtunding nervous sensibility He commended the use of unguents generally, they calmed the patient and reduced temperature He thought the use of the spray the best and most efficacious form of applying medication to the throat, and called especial attention to the use of chloral hydrate (two to four grains to the ounce of water), as invaluable for its antiseptic and anodyne powers The same salt possesses, he declared, exceptional merit in controlling convulsions happening in the course of the disease to children, and in such cases is best administered per rectum

Dr Moore also recommended the use of small doses of mercury for a few days, as an adjuvant to diuresis in the dropsy often attending acute desquamative nephritis, where diuretics were not accomplishing the desired end—failing with these means, a resort to hydragogue cathartics was indispensable Jaborandi he had not tried in the fever, fearing too much its depressant effects, the physiological action of the drug being comparatively easy to induce, but difficult to dissipate, or even diminish, when desired Nutritious food from the commencement of an attack, and free stimulation in all cases where the vital powers required sustenance, he regarded, of course, as measures never to be dispensed with

Afternoon Session

The afternoon session was taken up in

THE ELECTION OF OFFICERS

for the ensuing term, with the following results

President —Dr Rawley W Martin, Chatham, Va Vice-Presidents —Drs John S Apperson, Town House, T B Greer, Rocky Mount, and H M D Martin, Fredericksburg Recording Secretary —Dr Landon B Edwards, Richmond, Va Corresponding Secretary —Dr J F Winn, Richmond, Va Treasurer —Dr Richard T Styll, Richmond, Va To deliver Address to Public and Profession 1886 —Dr Hugh T Nelson, Charlottesville Nominated to the Governor as Examiner-at-large on State Board of Medical Examiners (to fill vacancy occasioned by death of Dr F D Cunningham) —Dr Thomas J Moore, Richmond, Va Examiner on State Board from Third Congressional District (to fill vacancy occasioned by resignation of Dr O A Crenshaw) —Dr Hugh M Taylor, Richmond Dr Meade C Kemper, Norfolk, Examiner from Second District Subject for General Discussion during next Annual Session —Puerperal Septicæmia Leader in discussion —Dr L Ashton, Falmouth, Va Place of next Annual Session —Fredericksburg, Va , *about* November 1, 1886

(*To be concluded*)

MISSISSIPPI VALLEY MEDICAL SOCIETY
(Formerly Tri-State)

Eleventh Annual Meeting, held in Evansville, Ind , Sept 8th, 9th, and 10th, 1885

(*Continued from page 355*)

TUESDAY, SEPT 8 —AFTERNOON SESSION

DR E S MCKEE, of Cincinnati, read a paper on

INTRA-CRANIAL CEPHALÆMATOMA

The word cephalæmatoma comes to us from the Greek It is an effusion of blood occurring in newly born infants, forming a tumor in the head The intra cranial variety, the subject of this paper, may be divided into *a*, Those situated between the skull and dura mater *b*, Those occuring in the arachnoid cavity As causes of intra cranial cephalæmatoma may be enumerated most of the causes of the external variety The reception of some injury to the child during parturition for example One can, however, find many instances where the external variety occurred, the labor being light They have been mentioned in breech cases, and in Vienna have been noticed on those whose births were due to Cæsarean section It is quite possible that through the crushing of the parts of the head together during delivery, there occur tearing of the periosteum or dura mater and bone blood vessels This pressure being released, the parts are again suddenly freed, emptied by the diapedesis caused by the crushing which they had undergone, hyperæmia and engorgement are the result of the removal of this pressure The sources of the hæmorrhage are probably the tender blood vessels These enter the bone from the dura mater, and are immediately after the release of the pressure overfilled and ruptured Possibly it might be due to a varicose condition of these vessels, or to the hæmorrhagic diathesis In cases of fracture of the bone cephalæmatoma on the dura mater may be due, only to the hæmorrhage from vessels wounded by the broken edges of bone M Vallier, in his "Clinique des Enfants Nouveaunés," has an engraving which illustrates beautifully the ease with which the blood may be caused to transude through the imperfectly ossified skull of the child The direction of the pressure during labor and the greater porousness of the outer layer of the skull compared with the inner, accounts for the excess of the extra over the intra-cranial variety Pressure, the usual causation of the former is quite adequate, if unusually forcible, to cause the latter

The diagnosis of intra cranial cephalæmatoma depends wholly, of course, on the symptoms of brain pressure, which it is liable to occasion These are twitchings, convulsions, stupor, or paralysis The external variety is of course much more easily diagnosed While the prognosis for the extra cranial variety is good, that for the intra cranial is bad Death occurs most frequently from brain pressure or from necrosis or caries of the bone leading to perforation, thrombosis of the cerebral sinuses, extension of the inflammation to the meninges and brain itself, and pyæmia Idiocy is one of the results of internal cephalæmatoma Dr West is the only one who has observed the cure of internal cephalæmatoma This was very analagous to the repair of the external The effusion became encircled by an osseous ring In one of the two cases noticed by Dr West convulsions came on in fifteen hours and terminated in death in four hours A large quantity of blood was found post mortem beneath each parietal bone The yielding structure of the infantile skull with its unossified sutures, is probably the reason why the effusion of blood upon the surface of the brain does not immediately and universally cause cerebral symptoms In one case of Dr West's all went to prove that the effusion beneath the dura mater must have existed many days before there were any cerebral symptoms

He then reported from the literature in brief twenty cases, one his own, which were all he could find Treatment, as yet, in internal cephalæmatoma has not been attempted, the diagnosis being always made post mortem Possibly there is here a field for the much-abused trephine

LOUIS BAUER, M D , F R C S , England, of St Louis, read a paper on

THE COCAINE HABIT

As a local anæsthetic, the hydrochlorate of cocaine has established its reputation beyond dispute, It is the safest, surest and most agreeable of the local anæsthetics Owing to the demand for knowledge concerning the physiological action of cocaine, and the fact that in a little less than seven months the patient had consumed about 700 grains of cocaine, and at times in very large doses, would seem sufficient to insure your interest and attention

The doctor had observed peculiarities about his patient before called to attend him On seeing that he was an object of interest, the patient avoided him at first, but finally came and told him all The patient descends from a confirmed drunkard At 13 he found whisky alluring, at 25 indispensable On the 9th of last January he had freely imbibed the indispensable beverage The last draught of ardent liquor was a pint of gin He had then just enough to submit to a hypodermic injection of cocaine under the promise that it would relieve him of a rousing headache, and probably quench his appetite for the "fire water" forever Unfortunately, the physician disclosed the name of the remedy, and the patient procured the article himself and used it on his own responsibility Thenceforward he used the cocaine injections, increasing the dose from one fifth to ten grains at a dose, and soon found himself in a condition demanding the continuous use of the drug Small doses of five to ten drops of a five per cent solution produced very mild yet appreciable effects on the patient

The following is an enumeration of the physiological effects

1 That none of the injections caused any inconvenience, either irritation inflammation of the skin, or abscess From the numerous insertions on the side and in front of the abdomen not the slightest mark remained, even recent insertions could hardly be traced

2 A small zone of integument, of which the punctured wound was the centre, showed a noticeable reduction of sensibility

3 The action of the cocaine invariably ensues within fifteen to twenty five seconds, in less than half an hour it is at its height, and within two hours it has almost entirely disappeared, when reaction gradually follows

4 The cocaine obviously exercises its first effect upon the heart, the pulse, ordinarily from seventy to eighty per minute, rises quickly to more than 120, but scarcely ever exceeds 130, it remains regular and shows no intermission, it is of medium size, slightly hard and continuous in that condition and that quality for the first two hours following the application, when it gradually diminishes in frequency and returns to the ordinary standard The patient insisted that intermissions had been frequently experienced by him, and that on locomotion the frequency would greatly augment I was, however, unable to affirm these observations

5 Among the earliest disagreeable symptoms of the patient is a burning sensation of the trunk and a cold and clammy perspiration of the extremities The thermometer did not however, reveal any tangible increase of animal heat, whereas the condition of the extremities was pronounced The temperature of both the mouth and the axillary cavity showed rather a decrease not exceeding one degree

6 When cocaine is in action the skin appears dry and pallid, but the patient avers that a profuse and clammy perspiration would ensue as soon as he assumed a recumbent position, in the latter the respiration becomes laborious, deep sighing and yawning

7 Whilst the moisture of the oval cavity remains undisturbed, the patient complains of a sensation of dryness and difficult deglutition, at one time the movements of the pharyngeal muscles were as painful as inflammation of the tonsil, but a new injection of cocaine removed the symptoms promptly

8 Whilst under the influence the patient is devoid of thirst, and would rather object to drinking any liquid on account of the disagreeable sensation it invariably produces

9 The cocaine destroys the appetite completely during its action, and gives rise to aversion for food, but the appetite returns when the effects have passed off

10 It induces constipation or intensifies the preexisting sluggish condition of the bowels, the latter may continue for a week or longer, and may require repeated large doses of drastic medicines, whereas in his ordinary condition a seidlitz powder would answer to move the bowels, at one time four cathartic pills induced diarrhœa, with painful tenesmus, a new dose of cocaine promptly subdued both

11 The secretion of urine ceases almost entirely for the time being, but returns when the patient comes out of the influence of cocaine

12 The sexual functions are likewise suspended to complete impotency during the action of the cocaine, their vigor returns, however, with rather increased appetite and endurance

13 The senses manifest exaggerated susceptibilities, the patient experiences a ringing in the ears as from quinine, when large doses have been employed, sounds become intensified, as in hydrophobia, without being painful, as in inflammation of the middle ear Light affects the optic nerve to a degree of intolerance, illusions happen, distorting objects, even hallucinations occur without fear or apprehension, the skin assumes a degree of sensibility so as to perceive an ordinary draught of air with the force of a blowing storm These phenomena relating to the senses are, however, exceptional, and only happen under the action of very large doses A common effect on the eye-balls is their prominence and brilliancy, connected with the dilatation of both pupils more so, however, in the left , This effect develops very gradually, appearing towards the end of the action, but extends into the intermissions of succeeding doses

14 Large doses of cocaine give rise to loquacity, notwithstanding that the patient avers difficulty of speech, for reasons already mentioned, his conversation is, however, clear, connected, and congruous with the subject concerned Most remarkable is the ability to remember names, dates, and events I have observed no aberration of the mind at all, it seems to me that the intellectual operations are in no way impaired

15 A few times whilst the patient was under the excessive influence of cocaine he complained about severe pains in his limbs, "electric shocks," as he expressed it, along the brachial plexus, sciatic and crural nerves, although they seemed not to interfere with active and rapid locomotion, they were increased by touch For the last fortnight these symptoms have not recurred

16 Most remarkable is the decided aversion for alcoholic liquors observed ever since the patient commenced to use cocaine in large and excessive doses

The writer thinks the cocaine habit most deplorable, but that cocaine has injured the patient less than excessive alcoholism would have done in the same time He has observed none of those organic disturbances in the patient's system which are so prominent from the abuse of alcohol By comparison, therefore, the former is preferable to the latter Dr Bauer is now trying it with several other patients addicted to alcohol, but has not as yet arrived at any positive conclusions

Dr James H Letcher, of Henderson, Ky, said he had found it necessary to inject the cocaine deeply into the tissues to get more than a very superficial anæsthesia

Dr James C Pearson, of Mitchell, Ind, read a paper on

PATHOLOGICAL CHANGES IN ACUTE AND CHRONIC DYSENTERY

He lamented the fact that in his little community it was impossible to get post mortem evidences of disease, as in the hospitals of large cities, because of popular opinion regarding it Alexander Trolles, some time in the sixth century, under the title of "Dysenteria Rheumatica," described an interesting state between that of inflammation and ulceration of the intestinal mucous membrane, in which shreds of the intestinal pseudo membrane were mixed with the discharges, stating that if protracted the first variety may pass into the second His views or description do not accord with our present knowledge of pathological anatomy On reading the pathology of dysentery we are at once impressed with the idea of its being a local phlegmasia, having the common elements of pyrexia or fever, local hyperæmia and local exudation In grave cases, attended with fever, what relation has the fever to the local affection, or *vice versa?*

Dr Bauer thought that the dysentery came from the constipation He had it twice himself from this cause, and treated many patients for it Instead of being eliminated, fæces corrode and form bad smelling gases Reported a case he had operated upon for stricture of the intestine If unable to obtain a post mortem from the patient's friends, he embalms him free of charge

Dr A C Bernays gave his experience in *Dilating the Rectum and passing the Hand and Arm into it* He reported Simon's views and experience in this operation On being asked if such a procedure was justifiable, he thought it was Being asked what advantage could be obtained, he said the kidneys could be palpated, stone or abnormal growths noticed The liver even could be felt in its lower border, adhesions of the peritoneum could be discovered The hand, he said, was not so crushed as to lose its sense of touch He reported the case of a quart bottle of champagne passing into the rectum of the man who sat upon it

Dr Beard, the President, reported the case of a very large *Fish Bone passing into the Rectum*

Evening Session

Dr J W Beard, in his official capacity, delivered the

PRESIDENT'S ADDRESS

He gave an interesting history of the origin of the Society, an abstract of which we have not space to give

Dr A C Bernays, of St Louis, Mo, read a paper on

NATURAL AND IDEAL CHOLECYSTOTOMY

He related a case of ideal cholecystotomy performed Sept 12, 1884, on Mrs O—r, of St Louis, who had been suffering for seven years almost constantly from biliary colic, with most excruciating pains accompanied with nausea, no jaundice, considerable emaciation, a large movable tumor in the right hypochondriac region Diagnosis impossible Explorative laparotomy He found a very much enlarged gall bladder, the cystic duct occluded by a firmly impacted calculus Punctured by trocar, emptying a clear mucous fluid Then incision and removal of twenty stones The large obstructing calculus was removed through the gall bladder in the same manner after considerable trouble Czerny-Lembert suture of the incision The bladder was dropped back into the abdomen The case progressed favorably, and complete recovery and relief of all symptoms followed The author then gave a careful review of the anatomy and physiology, and some points in the history of the operation on the bladder and ducts, and also descriptive of the operation of cholecystectomy and cholecystenterostomy By *natural cholecystotomy* is meant Sims' operation, which exactly imitates nature in its method of relief By *ideal cholecystotomy* he means the method which aims at immediate *restitutio ad integram* successfully practiced by himself

The paper concludes with the following propositions

1 The symptoms which indicate an operation, opening the system of gall vessels are, *a*, jaundice, *b*, paroxysmal pain, *c*, tumor in the region of the gall bladder *d*, suppuration, *e*, malignant disease, being either jointly or singly recognizable

2 Obstruction of the common duct is no contraindication of cholecystotomy, but we may often save life by its early performance

3 The incision in the linea alba must be preferred to the one parallel to the one in the free margin of the ribs, when the diagnosis is in doubt regarding the seat of the obstruction

4 Explorative laparotomy must be preferred to acupuncture or aspiration as a diagnostic measure

5 The escape of bile through an abdominal fistula is not injurious to the process of normal digestion The bile is an excretion, and probably has no more use in the intestinal canal than the urine in the bladder

6 Three operations are justifiable in the treatment of biliary obstruction They are cholecystotomy, ideal and natural cholecystectomy, and cholecystenterostomy

7 The operation of *ideal cholecystotomy* is indicated when the bladder and ducts are normal, and when all the ducts have been cleared of obstructing material

8 Natural cholecystotomy is indicated when the bladder is diseased, or when an obstruction is found to be immovable

9 Cholecystectomy should be limited to malignant disease of the gall-bladder Cholecystenterostomy cannot yet be classed among the legitimate procedures

Second Day—Morning Session

Dr L D Brose, of Evansville, Ind, presented a case of tient procured the article himself and used it on his own responsibility Thenceforward he used the cocaine injections, increasing the dose from one fifth to ten grains at a dose, and soon found himself in a condition demanding the continuous use of the drug Small doses of five to ten drops of a five per cent solution produced very mild yet appreciable effects on the patient

The following is an enumeration of the physiological effects

1 That none of the injections caused any inconvenience, either irritation, inflammation of the skin, or abscess From the numerous insertions on the side and in front of the abdomen not the slightest mark remained, even recent insertions could hardly be traced

2 A small zone of integument, of which the punctured wound was the centre, showed a noticeable reduction of sensibility

3 The action of the cocaine invariably ensues within fifteen to twenty five seconds, in less than half an hour it is at its height, and within two hours it has almost entirely disappeared, when reaction gradually follows

4 The cocaine obviously exercises its first effect upon the heart, the pulse, ordinarily from seventy to eighty per minute, rises quickly to more than 120, but scarcely ever exceeds 130, it remains regular and shows no intermission, it is of medium size, slightly hard and continuous in that condition and that quality for the first two hours following the application, when it gradually diminishes in frequency and returns to the ordinary standard The patient insisted that intermissions had been frequently experienced by him, and that on locomotion the frequency would greatly augment I was, however, unable to affirm these observations

5 Among the earliest disagreeable symptoms of the patient is a burning sensation of the trunk and a cold and clammy perspiration of the extremities The thermometer did not, however, reveal any tangible increase of animal heat, whereas the condition of the extremities was pronounced The temperature of both the mouth and the axillary cavity showed rather a decrease not exceeding one degree

6 When cocaine is in action the skin appears dry and pallid, but the patient avers that a profuse and clammy perspiration would ensue as soon as he assumed a recumbent position, in the latter the respiration becomes laborious, deep sighing and yawning

7 Whilst the moisture of the oval cavity remains undisturbed, the patient complains of a sensation of dryness and difficult deglutition, at one time the movements of the pharyngeal muscles were as painful as inflammation of the tonsil, but a new injection of cocaine removed the symptoms promptly

8 Whilst under the influence the patient is devoid of thirst, and would rather object to drinking any liquid on account of the disagreeable sensation it invariably produces

9 The cocaine destroys the appetite completely during its action, and gives rise to aversion for food, but the appetite returns when the effects have passed off

10 It induces constipation or intensifies the preexisting sluggish condition of the bowels, the latter may continue for a week or longer, and may require repeated large doses of drastic medicines, whereas in his ordinary condition a seidlitz powder would answer to move the bowels, at one time four cathartic pills induced diarrhœa, with painful tenesmus, a new dose of cocaine promptly subdued both

11 The secretion of urine ceases almost entirely for the time being, but returns when the patient comes out of the influence of cocaine

12 The sexual functions are likewise suspended to complete impotency during the action of the cocaine, their vigor returns, however, with rather increased appetite and endurance

13 The senses manifest exaggerated susceptibilities, the patient experiences a ringing in the ears as from quinine, when large doses have been employed, sounds become intensified, as in hydrophobia, without being painful, as in inflammation of the middle ear Light affects the optic nerve to a degree of intolerance, illusions happen, distorting objects, even hallucinations occur without fear or apprehension, the skin assumes a degree of sensibility so as to perceive an ordinary draught of air with the force of a blowing storm These phenomena relating to the senses are, however, exceptional, and only happen under the action of very large doses A common effect on the eye-balls is their prominence and brilliancy, connected with the dilatation of both pupils, more so, however, in the left, This effect develops very gradually, appearing towards the end of the action, but extends into the intermissions of succeeding doses

14 Large doses of cocaine give rise to loquacity, notwithstanding that the patient avers difficulty of speech, for reasons already mentioned, his conversation is, however, clear, connected, and congruous with the subject concerned Most remarkable is the ability to remember names, dates, and events I have observed no aberration of the mind at all, it seems to me that the intellectual operations are in no way impaired

15 A few times whilst the patient was under the excessive influence of cocaine he complained about severe pains in his limbs, "electric shocks," as he expressed it, along the brachial plexus, sciatic and crural nerves, although they seemed not to interfere with active and rapid locomotion, they were increased by touch For the last fortnight these symptoms have not recurred

16 Most remarkable is the decided aversion for alcoholic liquors observed ever since the patient commenced to use cocaine in large and excessive doses

The writer thinks the cocaine habit most deplorable, but that cocaine has injured the patient less than excessive alcoholism would have done in the same time He has observed none of those organic disturbances in the patient's system which are so prominent from the abuse of alcohol By comparison, therefore, the former is preferable to the latter Dr Bauer is now trying it with several other patients addicted to alcohol, but has not as yet arrived at any positive conclusions

Dr James H Letcher, of Henderson, Ky, said he had found it necessary to inject the cocaine deeply into the tissues to get more than a very superficial anæsthesia

Dr James C Pearson, of Mitchell, Ind, read a paper on

PATHOLOGICAL CHANGES IN ACUTE AND CHRONIC DYSENTERY

He lamented the fact that in his little community it was impossible to get post mortem evidences of disease, as in the hospitals of large cities, because of popular opinion regarding it Alexander Trolles, some time in the sixth century, under the title of "Dysenteria Rheumatica," described an interesting state between that of inflammation and ulceration of the intestinal mucous membrane, in which shreds of the intestinal pseudo membrane were mixed with the discharges, stating that if protracted the first variety may pass into the second His views or description do not accord with our present knowledge of pathological anatomy On reading the pathology of dysentery we are at once impressed with the idea of its being a local phlegmasia, having the common elements of pyrexia or fever, local hyperæmia and local exudation In grave cases, attended with fever, what relation has the fever to the local affection, or *vice versa?*

Dr Bauer thought that the dysentery came from the constipation He had it twice himself from this cause, and treated many patients for it Instead of being eliminated, fæces corrode and form bad smelling gases Reported a case he had operated upon for stricture of the intestine If unable to obtain a post mortem from the patient's friends, he embalms him free of charge

Dr A C Bernays gave his experience in *Dilating the Rectum and passing the Hand and Arm into it* He reported Simon's views and experience in this operation On being asked if such a procedure was justifiable, he thought it was Being asked what advantage could be obtained, he said the kidneys could be palpated, stone or abnormal growths noticed The liver even could be felt in its lower border, adhesions of the peritoneum could be discovered The hand, he said, was not so crushed as to lose its sense of touch He reported the case of a quart bottle of champagne passing into the rectum of the man who sat upon it

Dr Beard, the President, reported the case of a very large *Fish Bone passing into the Rectum*

Evening Session

Dr J W Beard, in his official capacity, delivered the

PRESIDENT'S ADDRESS

He gave an interesting history of the origin of the Society, an abstract of which we have not space to give

Dr A C Bernays, of St Louis, Mo, read a paper on

NATURAL AND IDEAL CHOLECYSTOTOMY

He related a case of ideal cholecystotomy performed Sept 12, 1884, on Mrs O—r, of St Louis, who had been suffering for seven years almost constantly from biliary colic, with most excruciating pains accompanied with nausea, no jaundice, considerable emaciation, a large movable tumor in the right hypochondriac region Diagnosis impossible Explorative laparotomy He found a very much enlarged gall bladder, the cystic duct occluded by a firmly impacted calculus Punctured by trocar, emptying a clear mucous fluid Then incision and removal of twenty stones The large obstructing calculus was removed through the gall bladder in the same manner after considerable trouble Czerny-Lembert suture of the incision The bladder was dropped back into the abdomen The case progressed favorably, and complete recovery and relief of all symptoms followed The author then gave a careful review of the anatomy and physiology, and some points in the history of the operation on the bladder and ducts, and also descriptive of the operation of cholecystectomy and cholecystenterostomy By *natural cholecystotomy* is meant Sims' operation, which exactly imitates nature in its method of relief By *ideal cholecystotomy* he means the method which aims at immediate *restitutio ad integram* successfully practiced by himself

The paper concludes with the following propositions

1 The symptoms which indicate an operation, opening the system of gall vessels are, *a*, jaundice, *b*, paroxysmal pain, *c*, tumor in the region of the gall bladder, *d*, suppuration, *e*, malignant disease, being either jointly or singly recognizable

2 Obstruction of the common duct is no contraindication of cholecystotomy, but we may often save life by its early performance

3 The incision in the linea alba must be preferred to the one parallel to the one in the free margin of the ribs, when the diagnosis is in doubt regarding the seat of the obstruction

4 Explorative laparotomy must be preferred to acupuncture or aspiration as a diagnostic measure

5 The escape of bile through an abdominal fistula is not injurious to the process of normal digestion The bile is an excretion, and probably has no more use in the intestinal canal than the urine in the bladder

6 Three operations are justifiable in the treatment of biliary obstruction They are cholecystotomy, ideal and natural cholecystectomy, and cholecystenterostomy

7 The operation of *ideal cholecystotomy* is indicated when the bladder and ducts are normal, and when all the ducts have been cleared of obstructing material

8 Natural cholecystotomy is indicated when the bladder is diseased, or when an obstruction is found to be immovable

9 Cholecystectomy should be limited to malignant disease of the gall-bladder Cholecystenterostomy cannot yet be classed among the legitimate procedures

Second Day—Morning Session

Dr L D Brose, of Evansville, Ind, presented a case of

FRACTURE OF THE SKULL

The patient, a child, while at play in the street Oct 12, 1884, was kicked in the head by a work horse heavily shod, and picked up wholly unconscious The doctor, in company with Dr W D Babcock, saw the child one hour after the accident He was still unconscious, had a rapid, feeble pulse, and widely dilated pupils Beneath the scalp was much effusion of blood just in front of the anterior fontanelle There was a lacerated wound, but no fracture of the bone beneath Along the right parietal eminence there was another lacerated wound, and a probe introduced here passed rapidly into the cranial cavity and revealed a single fracture of the right parietal bone, with much separation of fragments The prognosis was made that the child would live but a short time Nothing further being indicated, we applied cold cloths to the head and gave a few drops of brandy The next day the patient regained consciousness and was able to talk, but had complete paralysis of the left side of the face and left arm and leg, above each eye a bluish ecchymosis was noticed, but no subconjunctival hæmorrhage Fever, great restlessness and irritability occurred Bromide of potash, ten grs every two hours, was prescribed, and the cold applications were ordered continued On the third day the temperature became normal On the sixth a chill and fever occurred On consultation an exploratory incision was determined upon to liberate the retained pus, to see if there was depressed bone and liberate the same The incision revealed the presence of a depressed part of the parietal bone The adhesions to the dura mater were severed and the bone removed with the forceps The fragment embraced both tables of the skull, was wedge-shaped, with apex posterior, and about two inches in length Much pus escaped from the cortex of the brain after the incision The entire length of the fracture could now be examined with the finger The patient suffered very much from the operation, and was pulseless In four months the boy had recovered fully his former health and activity An opening still exists in the skull which by actual measurement is three quarters by five and three-quarters inches in its greatest measurement in the middle of the parietal bone Pulsation is distinctly seen through the cicatrix

Dr R W Amidon, of New York, in the *Philadelphia Medical News*, gives a good indication for opening the skull An injury of the vault, the marks of external violence, however slight, provided there be coma, aphasia, hemiplegia or hemi spasm of the lower part of the face of the arm or leg, all three constituting hemiplegia, whether or not accompanied by chills, fever, headache or vomiting General epileptic convulsions do not constitute so good an indication for operation Every case of compound fracture of the skull, whether there be cerebral symptoms or not, cases in which, after the lapse of months, or years even, unmistakable symptoms follow an injury of the head, atrocious and uncontrolled headache, particularly if localized, monoplegia, hemiplegia, seizures of general epileptic attacks, if they have an aura pointing to a localized lesion In addition to the bone the dura mater should be opened in all cases where exploration with a hypodermic needle discloses the product of a purulent inflammation, or a great deal of fluid under it In all cases in which a serious brain lesion is suspected, but cannot be proven otherwise

There are two conditions which, when present, demand an immediate resort to the trephine One is when the fracture is of limited extent and when there is reason to think, from the situation or the occurrence of monoplegia, monospasm or hemiplegia, that a splinter from the inner table may have penetrated the motor tract of the cerebral cortex The other case is one in which compression is caused by an accumulation of blood between the dura mater and cranium Such an accumulation may result from a wound of the larger venous sinus, but in the great majority of instances it depends on a wound or laceration of the middle meningeal artery The accident is most frequently accompanied by compound fracture, but it may be met with in cases of simple fracture, and occurs when no fracture is present In compound fracture, he believes that the trephine is to be recommended while the depression is marked but not of great superficial extent, and in all cases of punctured fracture where there is reason to suspect that the external plate is extensively splintered or depressed He is strongly opposed to active interference where the fracture is of great extent, and where the depression is not limited or abrupt He thinks that in many cases success will be attained by a careful antiseptic treatment of the wound, such as is recommended by Lister in the management of compound fracture of the lower extremity

DR WM A BYRD spoke concerning trephining He advised that it be used only in cases where spiculæ of bone were penetrating into the brain Do not let it start up inflammation He has had very good results with the trephine The last ten years have changed materially the surgery of the brain and skull

DR LOUIS BAUER said that fracture of the skull is simply reduced to this question Is there any pressure on the brain which is mechanically removable? We exhumed the body of a man hung in St Louis four years ago, and on examination, found the head smaller than his age and development would warrant We found the brain asymmetrical, flattened on one side and premature ossification of the bones of the skull The man was evidently in a state of semi-idiocy Irresponsible, he killed a man with a big stone, having no provocation I am satisfied that through his hanging, a judicial murder was committed He reported the case of an epileptic, very sullen, with other symptoms Found microcephalon Trephining was decided upon We took out two buttons and the intermediate ridge He improved wonderfully recovering completely his mental and physical health We have a new rôle for the use of the trephine He would not hesitate one instant to remove everything which interferes with the movement of the brain He discussed trephining for osteo myelitis What is more reasonable or rational than to make a hole in the bone and let it out?

DR A W BRAYTON, of Indianapolis said Dr

Bauer has reported cases which should come before a jury of medical experts He reported cases from Indiana, where judicial murder had been committed by a jury of farmers

Dr Joseph Eastman, of Indianapolis said how many children receive an injury in early life, and later become epileptic, insane, idiotic, and reach the asylum, possibly the scaffold! We must carefully consider these injuries and not trust too much to conservative surgery

Dr Chas Knapp, of Evansville, reported a case which occurred in his city The patient fell from a bridge a great height and with great force It was a case of much interest on account of the great force taken to fracture the skull It was found necessary to operate He thinks if there are symptoms of compression we should cut down Patient made good recovery except slight paresis of the limbs

Dr H H Clark, of Danville, Ill, asked if there was any change in the temperature of the boy Dr Brose replied that he had observed none Dr Clark advised that he be carefully watched for several years

Dr Brose, in closing, said he had hoped that some one would take up the subject of cerebral localization He explained that there was danger of depression of the parietal bone on pressure in the case he presented

Dr Edward Borck, of St Louis, read a paper on

ABDOMINAL SURGERY WITH REPORT OF CASES

At a former meeting of this Society, in this city, in 1879, the doctor read a paper before it entitled "Ovarian Tumors, at what Stage of the Disease is the proper time to Operate?" This was followed by a very interesting and instructive discussion One surgeon believed in the waiting plan He lost twelve patients in succession Another surgeon agreed with him in regard to waiting, and had the courage to say he had lost thirteen patients in succession Only one stated that he operated as early as he was able to make a diagnosis and his patient would let him He lost about sixty-six per cent of his cases He still adhered to his views then expressed in favor of an early operation, and to day he is able to sustain what was then his theory by experience

In March, 1878, he had his first case of ovariotomy A multilocular ovarian tumor in a lady 55 years of age, from the country He was advised to operate under the guidance and with the assistance of one who had operated, consequently he asked Dr Louis Bauer, of St Louis, to assist him The cyst was only of three months duration, and, all other surgeons who had been consulted, advised the waiting plan and against an operation at present The patient recovered

His second case was a lady, æt 43 He removed a large ovarian cyst from the right side together with the uterus, having had a cyst removed from the left side seventeen years previously, she died Next, a simple cyst of the left side in a young Miss æt 14, last stage, she also died But we learn much from our unsuccessful cases and eight successful cases followed The next case, ovarian cyst accompanied with cancer, was lost The next twelve cases recovered ' He then lost a case simple cyst, last stage Then followed a similar case which also died Out of the succeeding twenty-five cases he lost but one, a colored lady This makes fifty cases from March, 1878 to May, 1884, with five deaths These cases were divided as follows

Simple cysts	8
Cysts of the broad ligament	2
Ovarian cyst with cancer	1
Ovarian cyst with removal of uterus	1
Persistent pain in ovary, removal, cystic degeneration	1
Fibro cystic tumors	6
Oligo and polycyst, etc	31

These cases were all in private practice, all but five of them operated on in their own homes, and they were distributed in several States With the exception of those that died the cases were all early operations The youngest æt 14 years, oldest 60 years In two cases drainage tubes through the abdomen were used, in one a drainage tube through the vagina In these cases there was much surface bleeding In all the other cases the abdomen was closed The pedicle was dropped into the abdomen in every case In one case, a simple cyst, it was found necessary to open the abdomen again on the third day on account of internal hemorrhage The clotted blood was washed out and the wound closed again She recovered ' In this case he was led to use the cat gut ligature He will never use it again It is the doctor's custom to remain with his patients until they are out of danger, sometimes from three to six days He was not able to say what influence the air and malaria of Missouri had upon such patients, but it must have changed (?) since 1878, for other surgeons too were having brilliant success of late

Now when we know that the average life of a patient afflicted with ovarian tumor is four years, that polycysts terminate fatally in twelve months, oligocysts in twenty-four months after the third stage has begun, he draws the following conclusions 1 That those cases operated on in the extreme last stage die 2 That the comparatively early operations were successful 3 That there is no absolute need to send your patient off to a hospital or private institution if she is at all comfortable at home I always advise those gentlemen who attend my lectures, as well as others, to do as I do Take care of their own patients if they have the confidence in themselves to do so, but, if they do, by all means give their patient all their time and attention, and be well prepared for all emergencies

It has been intimated to me more than once, that I must pick my patients I will freely and openly admit that I do There are certain cases which I seem to know intuitively will turn out fatally These I avoid, for there must be the utmost hope and confidence on both sides

Here he related a case he had seen in Illinois, where he would have operated on Saturday, when he first saw the patient, as she was willing, but he was not prepared She would *not* permit an operation on Sunday, so it was deferred until Monday Being in the last stages she died Sunday night He thought an operation here perfectly justifiable Successful cases are reported from all over the country, even in small towns In the near future this will be considered a minor operation But how few fatal cases do we see reported I have seen many fatal cases in this country, not one of which was reported My friends say I pick my cases I would call it a judicial discrimination between cases, and recommend all who begin to do the same One thing my friends cannot say that I hide my fatal cases Every one of them has been published at once and in detail, and I will publish every other case I happen to have in the future for the benefit of all Since 1878 I have seen and examined on an average about twenty-five cases of abdominal enlargement per year, and I have not, in a single instance, made an exploratory incision for diagnostic purposes, though justifiable in many doubtful cases, and as a rule safe I do not believe in the practice of opening every woman's abdomen because it is easier to make a diagnosis I prefer the more difficult manner without the knife Whenever I should be in doubt, and have to resort to an exploratory incision, it would be with the distinct understanding to go on with the operation at once if such were indicated

DR BYRD had made a number of ovariotomies He never lost a patient if the tumor weighed less than thirty pounds He referred to picking patients Certain patients will die When you see little varicosities over the body it shows that the tissues are relaxed, that suppuration and peritonitis will intervene and the patient will die

DR EASTMAN questioned why is it that European operators are so much more successful than American? It is not in the air, and not in the patients It is a very important question to decide When shall we operate? Do not wait until the woman is weary of life I am not in favor of waiting any longer than to improve the general health of the patient No difference if the tumor is small, so much the better Lawson Tait says his patients come to him much earlier now than formerly Hence his better results He does not pick his cases The doctor referred to his opinions as expressed before the Indiana State Medical Society, and published All men can look back and say, " I do believe now, with my present experience, I could have saved that case "

DR H H CLARK, of Danville, Ill, has done nine ovariotomies, and has had two deaths Is confident that he could have saved one of those two with his present experience The tumor weighed forty-seven pounds Large tumors are not desirable for an operation He advocated early operations

DR LOUIS BAUER thought that there was nothing to be gained by delay The tumor interferes with general health, what can be gained by delay? Dr Borck is to be congratulated upon his courage in reporting his unfavorable cases

DR ARCH DIXON, of Henderson, Ky, reported the case of a woman he had operated upon, with a tumor the size of a head The case went without fever for nine days He then removed the sutures and found a little pus The temperature rose slightly He washed out the pus and the temperature fell to normal He also reported a second case

DR BYRD said the gentleman has discussed the present aspect of the case For the last five years he has used torsion in all operations except ovariotomies He has not had the courage to use it in this operation, but it has been used by Sims He may some day become prominent enough to do this in ovariotomy, he is now too young He has opened the abdomen seventy eight times and lost eight patients Do not put irritating material in the form of sutures in the abdomen and leave them there, they inevitably cause much trouble

DR BORCK, in closing, said he thought it well to send cases to the specialist, but if he dies, what then? New men must be coming on all the time He taught his students to perform their own ovariotomies He thinks Dr Byrd correct, that torsion can be used in this operation He thinks it proper to use the cautery after removing the secreting membrane

(*To be concluded*)

NECROLOGY

DR ROBERT McQUEEN GIBSON

This promising young physician was born in Troy, N Y, July 5, 1854, and died at the residence of his parents, in Portsmouth, O, July 3, 1885, lacking two days of being thirty one years of age He was the son of George and Isabella Gibson After attending the Portsmouth High School he began the study of medicine, and attended two courses of lectures at the Ohio Medical College At the close of his second course, and after a rigid competitive examination, he was a successful candidate for an Interneship at the Cincinnati Hospital for one year, which closed in March, 1877

Soon after this he associated himself with his preceptor Dr C M Finch, in Portsmouth, O, for the practice of medicine and surgery This partnership in time was severed, and the Doctor began practice for himself, erecting an elegant office on the corner of Fourth and Washington streets

Being well prepared and zealous in the performance of his professional duties, he soon acquired a large and growing practice, and throughout his life he retained the respect and confidence of the community and of his professional brethren He was a zealous and efficient worker in the local medical society, the Hempstead Academy of Medicine, was a member of the Ohio Valley Medical Association, the Ohio State Medical Society, and of the American Medical Association Early in March last, he was attacked with acute pleurisy resulting in empyema For four months he bore up bravely, and when told death was inevitable, he calmly replied that "it was all right," and that he hoped that he would not linger Death came to his relief at high noon, the city loosing a valuable citizen, and the medical profession a shining member

At a called meeting of the Hempstead Academy of Medicine, suitable resolutions were drawn up, the hall was draped for six months, and the Fellows agreed to attend the funeral obsequies in a body The remains were taken to Schenectady, N Y, for interment

DR JAMES H SNODGRASS

James H Snodgrass, M D, of Pittsburgh, Pa, was born in Washington County, Pa, and died in Hospital at Philadelphia, Pa, July, 1885, in his 53d year After acquiring a good academic education he began the study of medicine with Dr A M Pollock, in the city of Pittsburgh He attended the usual courses of medical lectures at the Jefferson Medical College, Philadelphia, where he received the degree of M D in 1866 Dr Snodgrass was fortunate enough to effect an arrangement with his preceptor, and at once began practice with him, which was continued to their mutual satisfaction for six or seven years His health, which was never robust, failed, and finally disease of the brain supervened some two years ago He was receiving treatment at one of the best institutions in the country at the time of his decease

Dr Snodgrass was a member of the Allegheny County Medical Society, the Pennsylvania State Medical Society, and a member of the American Medical Association since 1872 The Allegheny County Medical Society, at a special meeting held for the purpose, passed appropriate resolutions on his death

ASSOCIATION ITEMS

INFORMATION OF IMPORTANCE TO ALL MEMBERS OF THE AMERICAN MEDICAL ASSOCIATION

To the Editor of the Journal

Dear Sir —The notices which I send to members for payment of their annual dues bring to me so many inquiries as to the rules and customs of the Association, that I have deemed it advisable to call the attention of all your readers, as briefly as possible, to their responsibilities to the Association, viewed from my standpoint as Treasurer

Membership —Every one who attends an annual meeting of the Association as a delegate pays at that time five dollars, and thenceforward becomes a Permanent Member He continues as such as long as he remains in good standing in the body from which he was originally sent as a delegate As a Permanent Member, he must pay *Five Dollars Annually*, when notified by the Treasurer, whether he attends the meetings of the Association or not Payment of annual dues entitles him to receive the weekly Journal of the Association for one year

Members by Application are such as have not become Permanent Members in the manner above indicated, but apply to the Treasurer for membership, forwarding at the same time to him five dollars and the certificate of the President and Secretary of their State or local society, that they are in good standing in such society They pay five dollars annually thereafter, when notified by the Treasurer Members by application can join the Association at any time, and they receive regularly the weekly Journal

When Dues are Payable —The annual dues from Permanent Members are payable to the Treasurer at the time of the annual meeting of the Association, or immediately thereafter The payment entitles the member to receive the Journal for one year from the following July Payment for 1885, for example, entitles the member to the Journal from July, 1885, to June, 1886, inclusive

As some of the members have not yet forwarded to the Treasurer their dues for 1885, they are urgently requested to do so at an early day Having entered upon another year of membership, they are morally and legally responsible to the Association for the payment of their annual dues, having already received for three months of the new year—1885—the Journal of the Association

Subscriptions to the Journal, from those who are not members of the Association, should be forwarded to the office of publication, 65 Randolph Street, Chicago, and not to the Treasurer, but *all payments of annual dues must be forwarded to the Treasurer, Lock Box 1274, Philadelphia*

Deaths —When a member of the Association, who is in regular receipt of the Journal, dies, his family or other representatives are requested to inform the Treasurer at once of the fact

Payment of Dues for Previous Years —As a few members of the Association are still in arrears for payment of dues for 1883 and 1884, they are requested to forward at once to the Treasurer the amounts for which they are indebted to the Association

Transactions of the Association —These annual volumes, thirty-three in number, to 1882 inclusive, may still be obtained, with few exceptions, from the Treasurer, at reduced prices The Index to these volumes will be forwarded on receipt of *One Dollar* An opportunity is thus afforded to complete sets of these valuable publications, or to obtain important papers and works which are daily becoming scarce

Yours respectfully,

Richard J Dunglison, M D, *Treasurer*

Sept 25, 1885 Lock Box 1274, Philadelphia, Pa

MISCELLANEOUS

The American Public Health Association —The thirteenth annual meeting of this association, which numbers nearly 1000 members, will be held in Washington, D C, December 8, next, and is likely to continue in session a week

The local committee intrusted with perfecting arrangements for the meeting, which includes transportation and entertainment for the members of the association and place for holding the sessions, is as follows Dr Smith Townshend, chairman, J C McGinn, secretary, Dr J S Billings, U S A, John M Brown, U S N, Wm P Dunwoody, national board of health, Hon John Eaton, sr, Prof John Gamgee, Drs A Y P Garnett, A R Gihon, U S N, Walter Gwynn, Dr Chas H H Hall, U S N, C G Hirndon, U S N, Adrian Hudson, U S N, Mr E S Hutchinson, Drs J H Hidder, U S N, William Lee, George B Loring, De Witt C Patterson, Stephen O Richey, Charles Smart, U

S A , Thos J Turner, U S N , J M Toner, P S Wales, U S N , Ralph Walsh, Charles H White, T S Verdi, Mr Samuel A Robinson, and Dr D E Salmon

At a meeting of the committee, held at the health office on the 9th ult , a quorum of the members was present Dr Townshend announced that Dr Gihon had resigned the chairmanship of the reception committee, and that Dr Toner had been appointed in his stead

Dr Walter Gwynn, chairman of the committee on transportation, being compelled to be absent from the city, also resigned, and Mr Hutchinson was substituted, being transferred from the chairmanship of the finance committee, and the chairmanship of the latter committee was filled by the selection of Dr Patterson

The committee on reception will consist of twenty-five members, to be appointed by the chairman of the local committee upon consultation with the chairman of the reception committee The enlargement of the committee is left discretionary with the chairman

Mr Robinson, from the committee on securing a hall, reported that they had consulted the proprietor of Willard's and in consideration of the hotel being the headquarters of the visiting delegates, he would give the association the use of the hall free of charge, also the use of the hotel parlors for committee rooms Mr Staples, in addition, offered reduced rates for such of the delegates as became guests of the hotel The offer was accepted

Messrs Percy Smith, of the Baltimore and Ohio Railroad Company, Frank Trigg, of the Chesapeake and Ohio Railroad Company, and E J Lockwood, of the Shenandoah Railroad Company, being present, a general discussion in regard to reduction of rates was indulged in, but no definite action was taken

On motion, no subcommittee was authorized to create any indebtedness without the approval of the general committee The meeting adjourned subject to the call of the chairman

---

DR PAUL BORNER, editor-in chief of the *Deutsche Medicinische Wochenschrift*, died in Berlin on August 30, of acute peritonitis

DR L LUNIER, one of the founders, and the Secretary of the Association Française contre l'Abus des Boissons Alcooliques, died on September 5, at the age of 63 years

---

NEW YORK STATE MEDICAL ASSOCIATION —The first annual meeting of the Fifth District Branch will be held in Brooklyn, at the Mansion House, Hicks street, between Clark and Pierrepont streets, at 11 A M , on Tuesday, October 13, 1885 The following are the subjects of the papers

"Suggestions in regard to the Causation and Treatment of Acute Coryza," by AUSTIN FLINT, M D

"Further Observations on Diphtheria," by W H THAYER, M D

"The Physician and the Pharmacist—their relative duties," by J P GARRISH, M D

Report of a "Case of a Railroad Accident," by WM GOVAN, M D

Remarks on "The Milk Supply of Large Cities and the Improper Mode in which it is Conducted," by H A POOLER, M D

"Progress of Electrolysis in Surgery," by ROBT NEWMAN, M D

This being the annual meeting, a full attendance is especially desired Lunch can be obtained in the Mansion House on reasonable terms

J C HUTCHINSON, M D , *President*
E H SQUIBB, M D , *Secretary*

SURGEON-GENERAL OF THE MARINE HOSPITAL SERVICE —The President has decided not to make a change in this department, and has therefore declined to accept the resignation of Dr John B Hamilton, which was recently tendered to take effect on November 1st

---

M DUJARDIN-BAUMETZ, in a communication to the Academie de Médecine, states that it is an error to suppose that India-rubber cloths used in dressings are hurtful

---

WILLIAM AUGUSTUS GUY, the eminent English physician, and author of a number of medical works, died recently in London

---

SUCCESSOR WANTED

To a property and practice located in a beautiful Adirondack village—elevation 1700 feet above tidewater—popular and very favorable resort for lung patients and dyspeptics

An unusual opportunity to the right man Best reasons for selling, and all particulars on receipt of stamp Ready capital required, $1000 to $3000

Address DOCTOR,
Drawer A, Bloomingdale, Essex Co , New York

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE *MEDICAL* DEPARTMENT U S ARMY, FROM SEPTEMBER 19 1885 TO SEPTEMBER 25 1885

PROMOTIONS

Lt Col T A McParlin, Asst Medical Purveyor, to be Surgeon with rank of Colonel, to date from Sept 16, 1885

Maj B J D Irwin, Surgeon, to be Asst Medical Purveyor with rank of Lt Col , to date from Sept 16, 1885

Capt B F Pope, Asst Surgeon, to Surgeon with rank of Major, to date from Sept 16, 1885

APPOINTMENTS

Edward R Morris, to be Asst Surgeon with rank of First Lieutenant to date from Sept 17, 1885

Capt F C Ainsworth, Asst Surgeon, from Dept Texas to New York City, for duty as recorder of the Army Medical Examining Board (S O 214, A G O , Sept 18, 1885)

Capt Wm C Shannon, Asst Surgeon, granted leave of absence for four months, to take effect about Oct 1 (S O 115, A G O , Sept 19 1885)

OFFICIAL LIST OF CHANGES IN THE MEDICAL CORPS OF THE U S NAVY DURING THE WEEK ENDING SEPTEMBER 26 1885

Dungan, J S , Medical Director, waiting orders

THOUGHTS ON SOME POINTS CONNECTED WITH PNEUMONIA[1]

BY W P HART, M D,
OF WASHINGTON ARK

My object in this article will not be to follow the old beaten path in an essay on the subject of pneumonia Every standard author on the practice of medicine has furnished us with his chapter, while almost countless monographs have appeared on this subject While there is almost universal consent and agreement given to our teaching upon the subject of pneumonia and its treatment as a whole, yet upon some vital points there is not such happy accord and harmony While it would be profitless to attempt a review of our vast literature upon this subject or compile an essay therefrom, yet a few moments spent in the discussion of some doubtful points in regard to which there still exist diverse and conflicting opinions, may yield results of practical importance

First, is pneumonia simply an inflammation of lung tissue, purely local, or is it a constitutional disease with this local manifestation?

Secondly, should general blood-letting or venesection ever be resorted to in its treatment?

Thirdly, are blisters ever indicated or permissible in the treatment of pneumonia?

Fourthly, does this disease ever present a stage or condition in which belladonna is indicated and is the sheet anchor to the patient's life?

My remarks on these topics will not be for the sake of theorizing or for theoretical discussion, but to try, with the lights and experience we have, to arrive, if possible, at results and conclusions of the most vital and practical clinical importance to patients suffering of this malady And *first*, as to the nature of pneumonia, it is not a matter of indifference whether or no we entertain correct views, because upon those views will be based our practice, unless we propose, without reason or science, to adopt an empirical, hap hazard treatment, which is not complimentary to the practitioner, and should not be satisfactory to his patient Unless we propose to place ourselves upon the same dead level and plane with charlatans, we must first inform ourselves as to the work we have in hand No workman ever undertakes to perform a piece of work with certainty and success until he has informed himself as to the nature of that work No practitioner of medicine can propose to himself or promise his patient to treat any disease rationally and intelligently until he has learned the nature or character of that disease

Our predecessors for many long years viewed pneumonia as simply inflammation of lung tissue, and the spoliative treatment adopted by them was in keeping with those views And even now there are physicians who hold to the same pathological ideas If pneumonia be simply inflammation of lung tissue, and, *vice versa*, inflammation of the lung be pneumonia, certainly it should be treated antiphlogistically, just as it was treated fifty years ago, by blood-letting, purging, and a general depressant course But the frightful mortality attending this treatment is a fearful commentary upon it If the then prevalent and accepted idea of the nature of this disease (simply lung inflammation) was correct, the treatment they adopted, based upon that idea, was rational and scientific, and the mortuary statistics should have been very different and far more satisfactory The fatality attending this antiphlogistic treatment was simply appalling Even within my own recollection, to hear that a patient suffered of winter fever, as it was vulgarly called, was to learn that he, probably, had one foot already in the grave And so it continued until J Hughes Bennet called a halt, and adopted a conservative, expectant and supporting treatment, since which time the mortality has been reduced 250 to 500 per cent These results alone should be sufficient to convince us that either our ideas of the simple inflammatory nature of the disease were erroneous, or else, that anti inflammatory treatment is a delusion and farce

But putting aside these deductions, let us study for a little time a case of pneumonia prior to onset The attack is usually announced by a chill, most generally during the night, which lasts a longer or shorter time from a few minutes to several hours in duration, which is immediately followed by constitutional symptoms of greater or less severity the heart's action is accelerated and excited, as indicated by the number, force and power of its beats, the body heat is increased, the temperature running from a little above the normal to 104° or 105° F, with other symptoms corresponding At the onset of this chill there was none, at most but little, congestion even, much less inflammation of the lung What caused that paroxysm? Could it have been the effect of lung inflammation which, as yet, did not exist? If the chill announced the pneumonic attack, and at that time there was no lung inflammation present to produce that chill, how can we conceive that it was the effect or result of such inflammation? There was a cause producing that chill, there was no inflammation of the lung to produce it, hence it could not have been the effect of such inflammation. I have heard the suggestion advanced by the adherents of the local nature of the disease, that pneumonitis was an inflammation *sui generis*, peculiar and exceptional in consequence of the tissue involved. But, I would ask, is not simple, uncomplicated inflammation, whenever and wherever developed, identically the same, only modified and qualified, as to its activity or chronicity by the higher or lower organization of the structures involved? And when, in the course of an attack of pneumonia, the lung inflammation has been developed, wherein, I would ask, is it peculiar, or does it differ, as shown by its manifestations and symptoms, from inflammation in other structures or localities? The first stage, in which congestion and engorgement—the precursors of inflammation—are taking place, lasts on an average from twenty-four to forty-eight hours. Then follows the second stage—that of exudation or effusion and solidification—in which all the essential phenomena of inflammation are developed. But how was it possible that the earlier features and symptoms of the attack should have been the result of inflammation, which, until this time, was not and could not act as a cause, because it did not exist? Just as well say that the eruption of measles, scarlatina, or small-pox, that makes its appearance from the second to the fourth day of the fever, is the disease of which it is merely the manifestation. Would you say that a person suffering of the fever of rubeola did not have measles until the fourth day of that fever, when the eruption manifested itself? What sickened the patient from the outset but the measles? and what was the eruption but the outward expression of it? The eruption—the local inflammation—is the manifestation of the constitutional malady.

---

[1] Read before the State Medical Society of Arkansas, April 22 1885

Again, if the lung inflammation be the make-up and the whole of pneumonia, the gravity and intensity of the symptoms should have a direct and exact ratio to the extent and quantity of lung tissue involved. But from clinical observation and experience we know that this relation does not obtain. How often have we seen *great constitutional disturbance at the onset* and in the early stage, when physical signs gave evidence of but slight injury to the lungs? And in the sequel of the same case, when convalescence is about to set in and all the graver constitutional symptoms are yielding, the most marked evidences of lung troubles exist. The patient is convalescent because he has passed the crisis in his constitutional disease, and not because the lung inflammation—its local expression—is relieved, and the lung is soon convalescent for the same reason. Instead of the symptoms holding a direct relation to the extent of lung tissue involved, Flint, Sr., says, and the clinical observations of all of us confirm his views, that "the affection of an *entire* lung does not always give rise to symptoms denoting great gravity of disease. The febrile movement is not always intense and may be slight, the respirations may be but little increased in frequency, cough and expectoration may be not only not prominent, but even wanting, and the system may be but little disturbed. These remarks will also apply to double pneumonitis." How could this be if the lung inflammation were the sum total of the disease? Bartholow says "there is a growing belief that pneumonia is a constitutional disease. It differs from other inflammations in that it is self-limited, and terminates by crisis." These are features, I suggest, that characterize no ordinary inflammation. Fothergill says: "It is now generally recognized that pneumonia presents in itself no special indications for treatment." Again: "There is no treatment for pneumonia in itself." Why, I would ask? Is this true of ordinary inflammation? Is it not treatable and amenable to treatment? Verily so, but the lung inflammation in pneumonia is the attendant, the effect, the sequel of a disease, definite and certain in its course, and that terminates in a crisis just as certainly as measles, small-pox, or any other of the eruptive fevers, and is no more amenable to treatment or cure than they. This is Fothergill's idea, as I gather it. Again he says: "Our ancestors bled to death's door, while Rososi gave huge doses of tartar emetic. More recently J. Hughes Bennet has adopted the expectant treatment with liberal supplies of food. Every new remedy almost, in turn, is tried for pneumonia, and found to be followed by a large per cent. of recoveries, but in how many cases the recovery is rather in spite of, than in consequence of the treatment employed, is a doubtful question." And the same remark is applicable to other constitutional diseases with local manifestations, but never to simple, uncomplicated inflammation.

With the lights now before us we can realize and appreciate the mistakes made by physicians half a century ago in their attempts to cure pneumonia. Their effort was to strangulate, to jugulate, to cut short and cure the lung inflammation, not understanding and comprehending the true nature of the disease, and the result was the fearful mortality that attended this treatment. True, some patients recovered from the effects of this spoliative treatment, but it was because their vital powers were so strong and elastic that they reached a favorable crisis in spite of the doctor's well-meant, but ill-advised medication. And although physicians may still differ as to the nature of the disease, there is a marked sameness in their treatment. Even those who hold to the local nature of pneumonia, while they discard and ignore their most efficient and powerful agencies for its subjugation and cure,—to-wit, the antiphlogistic regime, they anxiously wait and look for the anticipated crisis, when the patient will pass through and make a safe landing upon the shores of convalescence. Now, instead of trying to master and drive nature, we content ourselves with watching and meeting exigencies as they may arise, until our patient shall have had time to get well, which will be the result in a vast majority of simple, uncomplicated attacks of pneumonia.

It is of the first importance, then, that we clearly recognize the true nature of pneumonia, and that it is not simply a curable inflammation to be jugulated by antiphlogistics, and thus, in our efforts to cure, thrust ourselves in the face of nature and thwart her means of restitution, but that it is a constitutional, self-limited disease that will run an exact, definite course, and terminate, most generally, in a favorable crisis, unless, by our meddlesomeness, we constitute ourselves the slayers instead of the rescuers of our patients

Should general blood-letting or venesection ever be resorted to in the treatment of pneumonia? If so, when and under what circumstances? These are questions of vital importance to every practitioner who is called upon to treat this disease, especially alarming and fatal, when viewed from the standpoint of fifty years ago If pneumonia be simply inflammation, we possess no agency so potent and prompt for its subjugation as the lance, but the great fatality that attended its indiscriminate employment was so shocking and appalling that it was finally almost totally abandoned, and for the last quarter of a century or more, it has been looked upon, by the vast majority of the profession, as the opprobrium of the healing art, and especially in the treatment of pneumonia, and to be dreaded more than the disease itself Is this right and as it should be? Because an agent—potent for good when discreetly and scientifically employed—is abused, is that sufficient cause why it should be totally discontinued and ignored? What, under the same ruling and judgment, would become of every prominent article in our materia medica? yea, of every bounty and blessing with which nature has supplied us? If formerly we bled too much, too frequently, too copiously, and too indiscriminately, is it not certain that we do not bleed enough at the present time? Because the attempt to cure pneumonia with the lancet proved a failure, is that conclusive evidence that it should never be employed as a temporary expedient or auxiliary in the treatment of that disease? I have been arguing against the idea that pneumonia was simply, and nothing more than, lung inflammation, and *a priori*, against a general and constant antiphlogistic régime that would be required to meet and combat it, yet do not cases sometimes arise in which the lance is not only permissible, but imperatively demanded? Prof Flint says, "Its employment is warranted when there is high febrile excitement, the heart's action being increased in force and power, and the patient of a robust or plethoric constitution" Unless some vital organ, previously weakened, be seriously threatened under the above conditions (and if such there be, the lance, I imagine, will be impotent for its salvation), I totally dissent from the above teachings, because pneumonia is not a curable inflammatory disease, but is definite, self-limited, and tending to a favorable crisis, while the effect of bleeding is spoliative, certainly and inevitably aggravating the very dangers that beset the patient later in his disease And because further, we possess other means and agencies with which, in ordinary cases and under ordinary circumstances, as indicated by Prof Flint, we can obtain quite all the good results promised by the lancet, without its serious spoliative effects, to which our patient may succumb at the very time when he should pass a favorable crisis

Without delaying to argue it I submit this broad, general proposition, that, in this latitude and climate, with their multifarious unending, debilitating and enervating causes, unless it be in exceptionally rare cases, venesection is never demanded or permissible to combat and control high inflammatory symptoms in pneumonic patients When reaction has been established and inflammation developed, there is no further indication for the lance, even if there had been any previously But there is a condition in which I have seen patients[1] die that I believe might have been saved by the lance if it had not been interdicted and prohibited by the ghastly horrors that cluster about its point in the minds of physicians, patients, and friends, and in which, should I ever see patients again, I will use the lance, though their lives, and my reputation and standing as a physician, may flow out and away with the venous current That condition is, when congestion is overwhelming, and the heart is about to be drowned in its own blood There is no accomplished inflammation as yet, but the patient's every organ and symptom indicate the most immediate and imminent danger, and I know of nothing half so likely as the lance to procure him the needed respite and relief The condition is that of great depression and prostration, characterized by general stasis and capillary congestion, and we can readily understand and comprehend how the relief is obtained The patient is dying under the first fell stroke in the congestive stage of his disease

The heart, the lungs, and every vital organ is being submerged and drowned, while his sensibility is so deadened and paralyzed that he is unconscious of his real condition He will tell you that he is not suffering, is not sick much, but will be well in a day or two, and is astonished if his watchful and observant physician expresses any apprehension as to his condition I have seen patients and friends die thus, and once, in just such guise, death invaded my own home circle The ordinary remedies and appliances having failed, what would you do in such a case? What will, if anything, avert the effects of this first dire stroke? I have searched my standard authors and journals in vain for an answer Not one of them even alludes to such a condition But the most of us, I imagine, at least the older members of the profession, have seen such cases, and we have tried and seen tried, fruitlessly and in vain, the whole routine of remedies and agencies usually employed in such cases Should not the lance be resorted to in such a case, in the hope that it might give new motion and life to the almost stagnant current? I have never resorted to venesection myself, nor am I acquainted with any physician who has, to relieve this condition, but everything else having failed, and death coming speedily on, should it ever be my misfortune to meet such cases again, which I pray God forefend, I will try the lance as a last hope, as a *dernier ressort* If then my patient dies I would have a conscience void of offense, knowing that I had exhausted the last resource in my efforts to save Except this condition, I know of none other in attacks of pneumonia demanding or permitting the use of the lancet

---

[1] In the Medical and Surgical Reporter of March 14 1885 I find an article by Dr Hiram Corson of Conshohocken Pa upon the Hygiene of the Aged' in which he refers very forcibly to this exact stage and condition, and suggests venesection for its relief

Our third inquiry is, are blisters ever demanded or permissible in the treatment of pneumonia? Here again we have quite a diversity of opinion and practice, arising mainly, I have no doubt, from a lack of positive and definite knowledge of the therapeutical effects of counter irritants "Ubi irritatio ibi fluxus" was the idea that obtained in the mind of the medical profession long years ago, and acting upon that idea counter-irritants were called into use There is a pretty general agreement in sentiment and practice as to the beneficial effects of counter irritants, excepting vesicants or blisters, but here there are conflict and diversity of opinion , If they are to be employed at all in the treatment of pneumonia, what are the indications demanding them, and in what stage of the disease? In the first stage, while congestion and engorgement are taking place, putting aside the annoyance and disturbance that necessarily attend their use, can they promise or accomplish anything more than mustard or other counter-irritants, in conjunction with warmth and moisture? If so, how? This is not the stage of the disease in which it is claimed, by those who believe in their beneficial effects, that they should be employed Prof Flint says, "blisters are not advisable on account of the general disturbance which they are apt to occasion, and their interference with physical examinations of the chest " I think this objection weak and insufficient, and, the latter part of it, unworthy its great author, because it would not be right to deprive a patient of the benefit that an agent or remedy might afford him, merely because it deprived us temporarily of part of our examination Prof Flint is a wonderful success and prodigy in the art of auscultation and percussion, and by these means can lay bare the conditions and workings of the thoracic organs as clearly as if they were exposed to the natural eye, but I think his protest against blisters, as stated above, more like an objection than a reason Fothergill says, "The utility of blisters in pneumonia is doubtful The advocates of such a plan have failed to furnish convincing evidence of the beneficial effects produced thereby " Bartholow says, "Counter irritation is useful during the stage of congestion, but a fugitive counter irritant, such as a mustard plaster, is all that can be properly used When the crisis occurs a blister is very useful " Although this last declaration may be true, the question naturally arises, how does he know it to be so?

Why is there such discrepancy among these authors on this subject? I can account for it only on the hypothesis, as stated before, of a want of definite and positive knowledge as to the action of these agents *During the stage of solidification and hepatization*, and about the crisis—the time when it is claimed they exert their most marked beneficial effects—we cannot account for their action upon the *proposition that where there is an irritation there is* a fluxus or flow, because the affected lung is already anæmic in consequence of the deposition having blocked up the vessels and deprived it, mechanically, of the usual amount of blood It is hepatized and solidified, the vessels ramifying it are clogged and blockaded, and consequently there is less blood in it than in health Hence, the object of blistering cannot be to divert or draw the blood from the solidified lung which it does not contain We must then look for some other explanation of their beneficial therapeutic effects in such cases, if really they produce such, and here, in the present state of our knowledge, we are at sea By what means a timely blister in cases of pneumonia, applied just as the patient approaches his crises, works its good results, whether through reflex nervous action, stimulation or otherwise, I know not, but that I have observed good results from the use of such a blister, and seen it assist greatly the patient to pass a favorable crisis, I firmly believe Yet, as the disease is self limited and terminates in a crisis, the same results might have occurred without the blister But feeling conscious that I have observed similar good effects from the use of blisters when applied in diseases that were not self limited and wont to terminate by crisis, I feel disposed to attribute the good results, in both instances, to the same agent, to wit, the blister

The fourth and last, but by no means the least important of my queries, is, does pneumonia ever present a stage or condition in which belladonna is indicated and is the sheet anchor to the patient's life? There is no allusion to it, as such, in any works upon practice, or in medical journals, at least I have made search, in vain, for something on this subject If I have ever seen or read anything upon the use of belladonna in the treatment of pneumonia, I have entirely forgotten it, and consequently can remember nothing of the ideas or suggestions contained therein Yet there is a stage and condition that sometimes comes up in the course of this disease in which, if anything, belladonna is the sure and only anchor to the patient's life When is the stage, and what are the conditions that indicate its employment? It will be observed that I restrict its use to a certain stage and to certain conditions, the stage is the period just preceding the crisis, and the conditions such as the following Frequency, or not and feebleness of the heart's action, a feeble, frequent and labored respiration, great dyspnœa rapidly tending to apnœa, pupils contracted almost to a point, in some cases a pale and cadaveric, in others an asphyxiated or cyanotic appearance of the patient, especially of the lips and extremities, the skin is relaxed and pouring out the patient's life, while the kidneys are refusing to perform their proper functions of waste elimination, and the mental faculties are being dethroned, either by violent and active or low muttering delirium While all the above symptoms will, probably, not manifest themselves in any one case, there will be enough of them to indicate great prostration and failure of the vital organs

What will we do for our patient in this condition? Opium, quinine, alcoholic stimulants, digitalis, nux vomica, ammonia, counter irritants with warm applications have all, or in part, been employed, and still your patient goes from bad to worse Now is the time for the application of the fly blister we say, but we can't tell why or how, and we employ it empirically, believing and hoping that it may do good in some unknown and mysterious manner, but still our patient is not relieved. What is the difficulty that these agencies have not wrought the desired and anticipated results? If we can determine that difficulty and then find some agent to meet it, then, instead of standing helpless and impotent with folded hands, watching our patient until life shall steal away from him, we can, with confidence and boldness, step in and rescue him. As stated before, the symptoms and conditions indicate great and general prostration. The nervous, circulatory, respiratory, and capillary systems are all depressed. In a word, there is an alarming loco blood-pressure present. The vaso motor nerves that supply the brain, heart, lungs, skin, and every vital organ in the economy, and contract their blood vessels, thus keeping up the normal blood pressure, are stunned, deadened, and partially paralyzed, while their antagonists, the vaso inhibitory or trophine nerves, are dilating these vessels, thus bleeding *the patient to death into the capillary* vessels of his own body at the expense of the proper blood supply to the vital organs, which are comparatively exsanguined and anæmic.

In consequence of the paresis of the vaso motor nerves, and the consequent absence of their contractile influence upon the blood vessels, coupled with the dilating influence of the vaso inhibitory nerves, the following conditions will necessarily be developed. Partial stagnation of the circulation, and undue amount of blood in the capillaries with sluggish motion and lowered blood-pressure, with all their attendant phenomena. Are not these the exact conditions with which we are brought face to face in the case of our patients? If now we can find some agent that will stimulate the brain and excite and arouse the vaso-motor nerves to their proper action and at the same time control their antagonists, the vaso inhibitory nerves, then we are prepared to meet the exigencies and demands of the case. I don't propose to say that we shall not employ auxiliaries, nor do I propose that belladonna is specially indicated except in the exact stage and under the peculiar conditions indicated above.

Now, let us examine the physiological effects of belladonna upon the system, and I am indebted solely to Prof. Bartholow for a discussion of these effects, as the account of belladonna and its physiological effects, as given by the U. S. Dispensatory, is insignificantly brief and worthless. And first as to the brain. The cerebral effects of large doses of belladonna are decidedly and markedly stimulating, as manifested by headache, vertigo, illusions, hallucinations, delirium, and even somnolence. The delirium may be gay and laughing or busy, or it may be noisy and furious, the patient fighting and striking all who approach him. In lethal doses convulsions may occur, or profound stupor may result after a period of delicious excitement. Under certain circumstances a tetanic action, very similar to that of strychnine, is developed. Belladonna, by virtue of its inviting a greater than normal transmission of blood through the tissues, increases metamorphosis, and the results of this are manifested in an increased diminution of waste products. So you will observe that it is a powerful stimulant and excitant to the nervous system, its effects even simulating and approximating those of strychnine. Upon the circulation its action is remarkable and unique. Its first and immediate effect is to slower the heart's action, but a rapid increase in the number of pulsations quickly follows. Not only is the number of the heart beats increased, but there is a corresponding increase in their vigor and form also, and the area over which the pulsations are distributed is enlarged. It has been conclusively proven that the increased action of the heart is due, first to stimulation of the cardiac ganglia of the sympathetic, and secondly, to a paralyzing action the pneumogastric terminal filaments. In other words, the motive power of the heart is increased in activity and force, and the inhibiting control is lessened. The stimulation of the vaso motor centres by belladonna is not confined to the cardiac ganglia, but extends to the vaso-motor ganglia throughout the body, and a general rise of blood pressure takes place, owing to contraction of the arterioles. It is a singular fact that the decided influence of belladonna rapidly produces a state of over excitation. Upon the function of respiration belladonna increases the number and depth of respiratory movements, but the increase is not in the same ratio as is the character of the pulse-beat. *The more rapid action of the heart*, the immense respiratory movements, and the contraction of the arterioles, result in an increased supply of blood to the periphery, more rapid nutritive changes and consequent elevation of temperature.

Do these physiological effects not meet and fulfil as nearly as possible the indications in our patient's case? And not theoretically or empirically, but rationally and scientifically, as the established and demonstrated effects of the drug? I recommend it in the condition indicated, not because some practitioner or experimenter employed it in a similar case and concluded it produced good results, as is the case with too many of our therapeutic agents, chief among which are blisters, but because its effects have been observed and proved, and we know that the article that will produce these effects must be beneficial in controlling and counteracting the symptoms in the condition indicated. We use it scientifically and rationally, not ignorantly and empirically. Blisters recommend themselves clinically, belladonna recommends itself physiologically and therapeutically. These are my views upon the action and utility of belladonna in the condition and under the circumstances indicated, and I wish I was able to elaborate and confirm them by a greater number of clinical cases than I have. It is but recently that my attention was directed to this article in such conditions, and I have but few cases to report in which its virtues have been tested.

Case 1.—Mr. R. H. P., white, 52 years of age, rather feeble and delicate physically, with an hereditary taint of tuberculosis in his family, several brothers and a sister having died of that disease, had a violent attack of pneumonia of the right lung, March 13, 1884 The attack was ushered in with a chill in the night of the 13th, and I was called to see him the following morning His case pursued the ordinary course under the present and approved treatment until the sixth day of his attack I proposed then to apply a fly blister, to which he earnestly objected on account of some preconceived prejudice On the morning of the sixth day of his attack his condition and symptoms were those of alarming depression and prostration, in spite of the soothing, supporting and stimulating measures I had employed with him His pulse was weak and feeble, but not rapid, his respirations were rapid, forty-two to the minute, shallow and labored, attended with great dyspnœa tending to apnœa, his lips, face and extremities were asphyxiated and cyanotic, and his skin relaxed and perspiring profusely In a word, there was great prostration of all the vital organs, with its attendant phenomena Would a fly blister have relieved him? I doubt it, for I don't know how it could have done so, and I have seen it fail of relief in so many similar cases But being acquainted with the physiological effects of belladonna, it occurred to me that they would meet the indications fully and exactly I put him upon four drop doses of the fluid extract of belladonna every four hours, and after three or four doses all of his alarming symptoms yielded, and in due time he passed a favorable crisis and made a good recovery

Case 2 [1]—"W A , white, age 45 years, was seen by me Nov 5, 1884 Condition, acute pain in right side, pulse 100, temperature 102° F Diagnosis pneumonia Put him upon the usual treatment, gave quinine every four hours in five gr doses, whisky, opiates and heart-sedatives Case took the usual course until about the fifth day, when great difficulty of breathing came on by spells at which times he had to be raised up in the bed to breathe, the perspiration pouring off of him I put a large fly blister over his side and put him upon carbonate of ammonia and digitalis Seventh day, condition unchanged, same treatment continued Blister drew well and was well filled I told the friends of Mr A I saw no chance for him, but would put him on the belladonna, as suggested by my friend Dr Hart Began the treatment on the evening of the eighth day Ninth day, condition much the same, except he had no more spells of difficult breathing and was not sweating He went into a typhoid condition, but finally got well"

I would suggest that, if the belladonna had been employed in this case on the sixth day, when the symptoms indicating its use first manifested themselves, its effects might have been more marked and decided I would suggest, also, that the surroundings of this patient were of the most unsatisfactory nature even the house in which he was sick being so open that it did not protect him against the changes and inclemencies of the season, and Dr Corrigan may congratulate himself upon being able to steer him safely through his attack

Case 3—"Saw Mr W on the 26th of December, 1884 White, age 59 Had been sick for a week and treated by Dr M , who, he said, had gone off on a spree could get no well authenticated account of what he had taken Present condition, pulse 120, temp 105° F , skin soft, cough very troublesome, spitting up frothy, bloody sputa Breathing rapidly Diagnosis pneumonia of left lung, the right did not seem to be involved Ordered large poultices over left lung, put him upon ten gr doses of quinine, alternated with ten drops laudanum, ten drops ergot F E , and five drops fluid extract of belladonna, to be given three hours apart He had spells of difficult breathing that came on every four hours I did not see him in one of those spells, but I considered the case a bad one, first, on account of his previous bad health, second, on account of his age, and third, because of the bad surroundings and previous treatment In consequence of high water overflowing the creeks, and inclement weather, I did not see him again until the 30th Treatment had been kept up as I directed, and on my second visit I discharged him He made a good recovery

"In both of these cases," continues Dr Corrigan, "I consider that belladonna acted well, and, judging from past experience in similar cases, I think both these cases would have died if it had not been for the belladonna"

Case 4—(Reported by Dr S M Corrigan) "January 30, 1885, I was called to see Mrs W age 33, white, who had a chill the previous day, followed by acute pain in the right side, diagnosis pneumonia involving entire right lung Pulse 98, temp 104° F Put her upon the usual treatment, but without apparent benefit She gradually grew worse until the morning of the sixth day, when her temp was 103½° F , pulse 90 and feeble, patient very restless, breathing difficult and labored, skin not acting properly, the expression haggard and anxious, all indicating a speedy fatal termination of the case At the suggestion of my friend Dr Hart, I put her upon the fluid extract of belladonna, four drops every four hours When I made my visit next morning, patient living four miles from town, to my great surprise and delight, I found her greatly improved, temp 101½° F , pulse 100, skin acting nicely, face of a rosy hue, had passed a good night, and, to use her own words, she said, 'Doctor, I am going to get well now, feel like I will be up in a few days' Continued treatment, and in due time my patient passed a favorable crisis I attribute my success in this case to the belladonna, I have used it in several other cases with decided benefit"

It may be objected that the apparent good results obtained in these cases were merely coincidences, and to establish the claims of this agent in the conditions indicated, a more extended and thorough experimental and clinical test must be employed The charge would be good and the insufficiency of the meagre statistics given admitted, if its beneficial effects in such conditions come to be established and proven by statistics, but I don't propose to base its merits and claims upon experiments clinical and empirical, but upon its known determined and established physiological actions and effects, which as certainly attend upon and follow its administration as effects follow causes Again, if belladonna is capable of producing the beneficial results I claim for it at this dangerous and critical stage of pneumonia, it is thrice welcome as coming to our help and relief at the very moment when other agencies have failed us, and our patients most need assistance In many instances, probably, the most prompt and effective action would be obtained by the use of atropia hypodermically And I would not limit it to cases of pneumonia, but extend its application to other diseases, should such a combination of symptoms arise as to demand an agent capable of producing the complex and powerful effects that follow the use of belladonna

---

[1] I am indebted to Dr A N Corrigan for the report of cases 2 and 3 and to Dr S M Corrigan for that of case 4

TETANUS[1]

BY WM A BYRD,

OF QUINCY ILL

Next to hydrophobia, I know of no isolated non-epidemic disease more dreaded by both the physician and patient than tetanus, a disease much more common in some districts than others, although the localities may be very near each other I wish to call attention to the two distinct beliefs in its nature One that it is humoral and zymotic, the other that it is a condition of reflex nerve irritation Now if it was zymotic in its origin, it should follow a more fixed course of symptoms than any cases that I have seen, or had the pleasure of reading the records of Take our well known zymotic diseases, and we know the different stages come on regularly and progress with a certain precision in all cases There may be cases much milder than others, but we never expect to see a case of small-pox end in a week or to commence without certain definite initial symptoms

Such is not the case with tetanus The initial stage may be all the way from half an hour to three weeks or even longer The other view, that it is a reflex nervous trouble, may be substantiated by the irregularity of the time that passes for the disease to manifest itself What the changed condition of the nerves is at the seat of the injury has not as yet been ascertained, but I cannot refrain from thinking that pressure has something to do with it In all the acute cases that I have seen, there has been an undue degree of tumefaction existing in the wound, and in the chronic cases the cicatrix has been unusually dense In all the acute cases that I have seen, it has been my practice to incise freely in the neighborhood of the initial lesion, removing, if I think necessary, some of the tissue to allow for swelling, then I have kept the patient under the influence of chloral hydrate and bromide of potassium to relieve them of the agony that they endure, and for the purpose of acting permanently upon the spinal cord, I have, at the suggestion of the late Dr John T Hodgen, given large doses of Fowler's solution In a case which occurred in Quincy, a few years ago, the patient had his hand mashed, in a little while, tetanus set in He suffered most excruciatingly, the opisthotonos was extreme, he was bathed in perspiration, and the lifting of the window curtain to let in more light, or a heavy step on the floor, or a draught of air striking him would cause him to beg piteously for some one to kill him and put him out of his misery I gave him twenty drops of Fowler's solution every two hours for over a week, watching carefully all the time for any symptoms of arsenical poisoning, that they might be met at once No such symptoms appeared, and he made a good recovery, and is now driving his team daily on our streets

A few weeks after I had discharged him, I was called to see a young laborer who had had his foot pierced by a large splinter Lock jaw set in, and, though not to severe, as in the first case, I put him on the same treatment In two weeks he was greatly improved but exposed himself on a cold rainy day, had a relapse and died

In regard to the method of treating chronic tetanus perhaps it will be just as well to report a case that was one more interesting, to me, than any I have ever known The morning of July 18th, I met Dr M Rooney, the physician to St Mary's Hospital and he informed me that there was a case of tetanus at the hospital that had entered as a case of paralysis, from a diagnosis that had been made at one of the public institutions in St Louis He further stated that the man had received an injury on the head When I reached the hospital, I found a well nourished man, about 35 years old, with set jaws and spasm of all the muscles of the body He stated that three weeks before, while working on a bridge he fell, striking a stone and inflicting a wound over the right eye The wound soon healed, but in about ten days he began to get stiff, could not walk well, had difficulty in chewing his food, and at night would have spasms of the general muscles, with excessive perspiration This becoming worse, he went up to St Louis, where his trouble was pronounced paralysis Having friends in the North, and the outlook being so gloomy, he determined to make his way to them, but when he got to Quincy, he felt so much worse he stopped at a hospital

The case was a plain one of tetanus The scar on the eyebrow showed that it was recent and also that it involved the superior orbital notch He was put under an anæsthetic, and the cicatrix cut out As soon as the bone was reached a fracture was discovered I applied the trephine, removed the injured bone, and dressed the wound As he recovered from the anæsthetic he vomited, and having by some means swallowed some large pieces of beef's liver, they could not pass through his clenched teeth, so they took the next best direction, that of the least resistance, and went down the trachea Then there was confusion, the attendants all declaring that the man was dead, and so he seemed Right then I began to have a deep and abiding sympathy for the surgeon that loses his patient during an operation I was utterly unprepared for a tracheotomy, with the exception that I had pressure artery forceps and tenacula out of the case, as also a scalpel I quieted them by telling them that it would take the man at least a minute to choke to death, and that as I could perform tracheotomy in half a minute, that we had plenty of time I picked up the scalpel and laid the trachea open for at least an inch below the cricoid cartilage, incising the superior thyroidal vessels The flow of blood was appalling, but passing my finger into the trachea so as to lift it and the accompanying tissues, I seized the vessels on either side of the cut *en masse* with pressure forceps, and stopped the hæmorrhage at once We then proceeded to get the liver out of the trachea, which we easily did by holding the wound open with tenacula The mass of liver was fully as large as my whole thumb After clearing out the trachea, I inserted two sutures on each side of the wound in the trachea to the edges of the skin, and fastened the ligatures to pieces of adhesive plaster, and drew them back over the shoulder so as to hold the wound gaping, a method introduced by one of the greatest and most original surgeons America has ever claimed, the late Dr Henry A Martin, of Boston I digress here, to call your attention to this method of performing tracheotomy, because I have performed tracheotomy, and had the nurse, a physician, fall asleep and allow the tube to become blocked up with mucus and strangle the patient That event has given me a horror of tubes in certain conditions

---

[1] Remarks before the Mississippi Valley Medical Society Sept 9 1885

The patient was put upon chloral and five drops of Fowler's solution every two hours In three or four days erysipelas set in and involved nearly his whole face That lasted for about a week, when he got better In about two weeks he was so much improved, that I changed him into a convalescent ward His bed was so placed that he was in a draught The next morning when I came to the hospital, he was suffering with acute laryngitis, and I found it necessary to reopen the trachea to allow him to breathe Not being prepared to hold the trachea open as before, I took two hairpins and bent them into the letter S shape, and by fastening tapes to one hook and putting the other end of the hook in the trachea, and tying the tapes behind the neck, I succeeded admirably in holding the wound open That looked so much like barbarous surgery, that I brought out a large tracheotomy tube in the afternoon, and taking the hairpins out, replaced them with the tube, but when the patient would cough, it would cause the mucus to block the tube and he would not tolerate it, but made me take it out and replace the hairpins These he wore for about a week, when the inflammation in the larynx having subsided, they were taken out and the wound quickly healed He went on to a perfect recovery and was discharged from the hospital well, September

P S —Since writing the above, Frank Cason, a 5 year old son of Robert B Cason, living nine miles west of La Grange, Missouri, has been brought to me suffering with tetanus, the result of a fracture of the skull from the kick of a horse, over the outer side of the orbital eminence The fracture was undetected and the flesh wound healed Ten days afterward he exhibited strange symptoms, and the physicians that saw him pronounced it a case of paralysis When I saw him I detected at once, lockjaw from depressed fracture of skull September 18, just two months after the first operation, I cut down through the scar, at St Mary's Hospital, with the assistance of Drs Rooney, Woods, Rook and several medical students, and took out a depressed fragment of bone as large as the last joint of my little finger The child is doing very well, being better as soon as he was from under the anæsthetic

ABSTRACT OF A PAPER ON THE SUCCESSFUL TREATMENT OF LACERATIONS AND FISSURES OF THE OS UTERI OF LONG STANDING WITHOUT SURGICAL OPERATION[1]

BY BEDFORD BROWN, M D,

OF ALEXANDRIA VA

During the past twelve years the writer has embraced every opportunity to test various means for the purpose of devising some method of treating these injuries successfully, without resort to operations A very large proportion of females suffering from these afflictions have neither the means nor the opportunity of seeking the aid of the specialist The writer believes that he has perfected a simple method which can be used by all practitioners of intelligence for the treatment of these cases successfully with time and care without the necessity of operation The agents resorted to in this method are entirely of a local character

Concealed fissures are often found after labor in the mucous membrane of the cervical canal, and are the cause of an infinite amount of local disease in the form of endocervicitis, hypertrophy of the adjacent tissues, inflammation of the submucous fibrous tissue, leucorrhœa, and often painful menstruation One of the most usual seats of these fissures is at the internal os Here the mucous membrane and submucous structure is split through, often to a considerable depth The rent here, as in the case of fissure of the rectum, will remain as a source of trouble for years

It is highly probable that these concealed fissures are the prime cause of a very large proportion of the cases of cervicitis and their consequences, found in women who have borne children The No 1 solution of nitrate of silver reaches these wounds effectually, stimulates a new action, and heals them from the bottom readily

With a view of promoting the healing of the open lacerations and fissures, however small, which act as a centre for the radiation of morbid influence, I have tested every standard agent as a local remedy—Churchill's tincture of iodine, Battey's solution, pure carbolic acid, iodoform, chromic acid, solid nitrate of silver They all failed signally to promote healing and closure of the laceration The application of the solid nitrate of silver invariably acted as a violent irritant, increasing inflammation, pain, discharge and hæmorrhage Finally a solution of crystals of nitrate of silver, graduated so as to adapt it to the particular parts to be applied, and the various stages of progress, was used The effects of this agent proved that lacerations and fissures of long standing and the most aggravated character, complicated with great degree of inflammation, hypertrophy, subinvolution, and a certain degree of pelvic cellulitis, were curable An experience in the use of this agent in about twenty cases of lacerations and fissures, from the slightest to the most aggravated form, treated in the past ten years, shows conclusively that the most extensive wounds (many of them bilateral), have been made to heal and close up permanently The os and cervix have invariably been reduced to their natural appearance and dimensions without contraction

---

[1] Read before the Medical Society of Virginia Sept 17 1885

The treatment requires for completion from six to twelve weeks It can be resorted to regardless of the presence of hypertrophy, inflammation, cellulitis, or subinvolution The solutions employed were of three different grades

SOLUTION NO I

℞ Argent Nitratis (cryst) ʒss
Aq distil f℥i M

This is the form to be applied to the interior of the cervical canal, which is always in a state of catarrhal inflammation arising from the laceration or fissure which penetrates it The remedy is applied down to the os internum by means of a silver or whalebone probe, wrapped with absorbent cotton

SOLUTION NO 2

℞ Argent Nitratis (cryst) ℈iss
Aq distil f℥i M

This solution is to be applied, or rather freely painted, over the external surface of the os and cervix uteri, by means of a large camel's hair brush, including the cavity of the laceration and granulating surface, until the whole presents the appearance of a grayish white coating The application usually gives no pain, but rather acts as a soothing or sedative agent, protecting the exposed sensitive branches of the torn nerves and the tender granulations The coating will often remain from one to three days While the remedy acts as a protective, it also acts as a mild but decided stimulant, to develop a new and more vigorous growth and a more healthy action Thus underneath this coating of silver the processes of healing and filling up the gaping wounds and the formation of a healthy cicatrix are in active operation

At this stage the remarkable action of the remedy is manifested in the reduction of engorgement, in stimulating the process of absorption, and in removing all hyperplastic deposit and hypertrophy By changing the morbid action in the wounded part, and affording an impervious coat, it suspends the absorption of septic matter and interrupts the action of the cause of cellulitis, which gradually subsides under its influence The silver applied in this manner never acts as a caustic or destructive agent, but only as a stimulant to vital action

SOLUTION NO 3

℞ Argent Nitratis (cryst) ʒiss
Aq distil f℥i M

Solution No 3 is not only designed to be applied to the external surface of the cervix uteri, after the healing and closure of the laceration have been completed, but also when there remains a degree of hypertrophy or hyperplasia, or ordinary engorgement, accompanied with induration A solution of this grade will generally reduce these conditions and leave the cervix soft and healthy

It is unsafe to leave the cervix either in a hypertrophied or engorged state, as that might be the basis of future inflammation and reopening of the wound A majority of the cases thus treated have since given birth to children Some have borne three children since treatment without difficulty All have been entirely relieved of all unpleasant symptoms Examinations held after the birth of each child showed a perfectly healthy os and cervix

The application should be made every four days During the intervals a douche of warm water, for the purpose of removing any accumulation of secretion, should be resorted to every morning

It is the custom of the writer, in all cases of labor under his charge, to make a digital examination, at the time of the delivery of the secundines, of the os uterus, with the design of ascertaining the presence of laceration If it exist, warm water douches containing biborate of soda, boracic acid, and carbolic acid in solution, are used after the first day, with the intention of maintaining a perfect state of antisepsis, thus preventing infection, and promoting the healing of the wound by first intention, if possible If fever and cellulitis should come on notwithstanding this procedure, where no laceration can be detected, it would indicate the existence of a concealed fissure deep down in the cervical canal near the internal os, which has never been reached by the antiseptic douches In the event that healing by first intention fails to occur, antiseptic treatment and cleanliness of the wound are continued, and after two months the local treatment is commenced with the graduated solutions of nitrate of silver, with the certainty of a speedy restoration

BROMIDE OF ETHYL IN LABOR, AND CLAIMS CONCERNING PRIORITY OF ITS USE

BY H LANDIS GETZ, M D ,

OF MARSHALLTOWN IOWA

I have recently noticed some contributions upon the use of bromide of ethyl in labor,—and while I have not lately used the drug, I have done so in the past, and can give something of an experience relative to its effects upon the patient in confinement

Some time during the month of January, 1880, I received a pamphlet from Dr R J Lewis, of Philadelphia, who had used the drug in surgical practice, wherein were set forth its uses and advantages as an anæsthetic in surgical operations Being always a decided advocate of the use of anæsthetics in obstetrical practice, the idea occurred to me that if the new anæsthetic was what was claimed for it, it would certainly also answer a good purpose in obstetrical cases, and might possibly possess advantages over chloroform, and in a paper read before the Iowa State Medical

Society, which convened at Des Moines, January 27, 1880, I suggested the use of the drug in obstetrical cases. Shortly afterwards I procured the new anæsthetic and inhaled some of it, that I might compare in a degree its effects with those of chloroform and ether. I found that it produced in a measure the excitement and disposition to talk, which is peculiar to the primary effects of ether, and while anæsthesia could be as quickly produced with ethyl as with chloroform, it did not last so long. I also observed in my own case, and in others, that there was more nausea and vomiting and headache when the ethyl was used, than with chloroform. I also used mixtures of ethyl and chloroform, but found in them no advantages over chloroform alone. I make the following objections to bromide of ethyl.

1st. It is no safer than chloroform.

2nd. I can produce anæsthesia as quickly with chloroform.

3rd. The same *degree* of anæsthesia does not endure so long as with chloroform.

4th. It produces more nausea, vomiting and headache than chloroform.

5th. The odor and taste is more unpleasant than that of chloroform.

6th. It possesses no advantages over chloroform in obstetrical practice.

7th. In prolonged obstetrical operations it is not so good as ether, because the anæsthetic effect is of short duration, and as a consequence requires to be continuously administered.

8th. For these reasons, I have abandoned the use of it.

Concerning priority in the use of bromide of ethyl in labor, Dr. E. E. Montgomery, in a supplement to a paper read by him before the Obstetrical Society of Philadelphia, and published in the JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, of September 26, 1885, writes as follows:

"In following the German literature by which I was led to use this drug in labor, I ascribed its first obstetrical use to Lebert, of Paris. The first case in which he used it was for the application of forceps, and occurred in March, 1881, but a paper published by Dr. Turnbull, (*Med. Bulletin*, June, 1880,) shows that he had then used it in a second case of labor, and spoke in high terms of its peculiar advantages. Dr. H. Augustus Wilson had used it in labor prior to August 7, 1880, when he published an article on this drug. (*Medical and Surgical Reporter*, Aug. 7, 1880.)

"It becomes quite evident that the first obstetrical trial of this agent was made in this city, and the priority lies between the gentlemen named."

Now, accepting Dr. Montgomery's dates as correct, I lay claim to priority of use of the drug in obstetrical practice, by a year over Lebert, of Paris, and by months over Turnbull and Wilson, of Philadelphia. In a paper read by me at the Iowa State Medical Society (as already indicated) which convened at Des Moines on January 27, 1880, on "The Use of Anæsthetics in Labor," I suggested the use of bromide of ethyl for this purpose (see extract of paper published in *New York Med. Record*, February 21, 1880). The first case in which I employed the drug occurred on March 29, and the second case March 30, 1880, as my obstetrical memoranda, made in my "Visiting list" for 1880, show. These facts, I believe, *clearly* leave with me and in the West thus far, the credit of priority of the use of bromide of ethyl in obstetrical practice, *instead of* at Paris or Philadelphia, or with the gentleman whom Dr. Montgomery unintentionally placed it.

204 E. Main St., September, 1885.

MEDICAL PROGRESS

PILOCARPINE IN DATURA-POISONING.—DR. LADISLAS ROTH, of Nagy Bajour, Hungary, was called, at 1 P. M., to a little girl, aged 4, in a druggist's shop. She was quite insensible, with widely dilated and insensitive pupils, the face and body being swollen as if dropsical, and covered with a scarlatiniform rash. She was very restless, throwing herself about in all ways, groaning and gnashing her teeth, the pulse was 146, small and weak, the respirations forty, superficial, the temperature 39.5° Cent. (103.1° Fahr.). No urine or stool had passed since the commencement of the symptoms. The mother said that other children had told her that the child had eaten two handfuls of sweet ripe stramonium-fruit, and, when she saw her at eleven o'clock, she had seemed ill, and unable to stand on her feet. She had called the Government medical officer, who prescribed a mixture containing two grains and a quarter of tartar-emetic. The druggist, however, being of opinion that that would not do any good, took upon himself to give a solution of sulphate of copper instead. In the vomit which the copper had produced a number of berries of datura stramonium were seen. Dr. Roth, remembering a case of atropine-poisoning he had seen reported by Professor Purjek, which had been cured by pilocarpine given subcutaneously, administered, at twelve o'clock, half a centigramme (one fourteenth grain) of pilocarpine, in five centigrammes of water, by means of a Pravaz's syringe. No salivation or sweating followed, but no improvement was detected, and, at a quarter to three, a centigramme was given. The red rash and the swelling diminished. At three, another centigramme was given. The child cried, and shortly began to show various signs of improvement, even answering, "Yes," when the mother asked if she were ill. The injections were continued. Up to five o'clock, five and one half centigrammes had been given. At six, the pupils had become almost normal, and the pulse 120, and temperature 39.8°. She was able to speak quite plainly, and wanted something to eat. All this time, there had been no sweating. At seven o'clock, as her condition appeared somewhat less satisfactory, half a centigramme more was given, and this brought on both salivation and sweating. She made a rapid recovery. Altogether, six centigrammes of hydrochlorate of pilocarpine were administered, five of which, the writer considers, were required to neutralize the datura.—*Brit. Med. Journ.*, Sept. 19, 1885.

THE
Journal of the American Medical Association.
PUBLISHED WEEKLY.

The Editor of this Journal would be glad to receive any items of general interest in regard to local events or matters that it is desirable to call to the attention of the profession. Letters written for publication or containing items of information should be accompanied by the writer's full name and address, although not necessarily to be published. All communications in regard to editorial work should be addressed to the Editor.

Subscription Price, Including Postage.

Per Annum, in Advance	$5.00
Single Copies	10 cents.

Subscriptions may begin at any time. The safest mode of remittance is by bank check or postal money order, drawn to the order of the undersigned. When neither is accessible, remittances may be made at the risk of the publishers, by forwarding in registered letters.

Address,
Journal of the American Medical Association,
No. 65 Randolph Street,
Chicago, Illinois.

SATURDAY, OCTOBER 10, 1885.

MODESTY!

The *Medical News* and the *Record* are still laboring to make the professional world believe that there are no leading men in the profession of the United States except the twenty-eight in Philadelphia, the dozen in Baltimore, and the half dozen in New York who refused to accept positions in the International Medical Congress, "as then *proposed* to be organized," before the actual organization had been effected; and they are still publishing pretended declinations from the same "proposed" organization. The *News*, however, seems to be rapidly losing its interest in the whole subject, and in its last week's issue lugubriously expressed the hope that "the nation may be spared the disgrace" of having the Congress held in this country. Perhaps the fact that the unpatriotic conduct of that journal and its twenty-eight coadjutors has been openly condemned by one hundred and fifty of the leading members of the profession in its own city, and three or four hundred more in the State, is having something to do with its waning interest. And there is some reason to hope that its corps of editors will ere long actually discover that there is a medical profession in the United States outside of that editorial corps and its little coterie of favorites.

The *Record*, with still more remarkable modesty, openly declares "that there is no exaggeration in saying that there are not half a dozen representative men in the profession now who are prominently connected with the organization of the Congress." As Austin Flint, Sen., is President, W. O. Baldwin, H. I. Bowditch, Wm. Brodie, Henry F. Campbell, W. W. Dawson, R. Palmer Howard, E. M. Moore, T. G. Richardson, Lewis A. Sayre, and J. M. Toner, are among the Vice Presidents, and Henry H. Smith, Wm. H. Pancoast, A. R. Robinson, Wm. T. Briggs, Joseph Jones and John P. Gray, are among the Presidents of Sections, the question will naturally arise in the mind of the reader whether there are any "*representative*" men in the profession of the United States in the estimation of the *Record* except its editor, George F. Shrady, A.M., M.D.

A week or two since, the editor of the same journal, in asserting its usual pretense that the action of the Committee of Arrangements was condemned by the whole profession and the medical press, actually named eighteen medical journals out of the one hundred or more published in the United States, that had sometime published expressions of disapproval of the action of the Committee of Arrangements. But to get even this relatively small number of journals, he had to include the *Chicago Journal and Examiner*, whose editor simply admitted in its columns that errors had been committed on both sides, but is himself an earnest supporter of the present Preliminary Organization of the Congress, and President of one of its Sections. While both the *News* and *Record* find plenty of space to copy from week to week, under the head of public sentiment, the comments of their little coterie of journalistic followers, neither of them has had the manliness to publish the official report of the proceedings of the Committee of Arrangements as finally adopted at the meeting in New York, so that their readers could read and judge for themselves concerning both the appropriateness of the Rules and the *personnel* of the Organization.

The truth is, that the Rules as finally adopted and the Organization for which they provide are free from every objection that had been urged against the previous work of the Committee, and further opposition can have no other basis than mere personal prejudice or the unpatriotic desire to drive out of the country whatever the opponents cannot personally control. But they may rest assured that further opposition on either basis will be unavailing. The Ninth International Medical Congress will be held in the City of Washington in 1887, and will be equal, in all its legitimate interests, to any of the Congresses that have preceded it.

BACTERIAL THERAPEUTICS.

The recent experiments of Professor Cantani regarding the effect of administering, by inhalation, a spray of bacterium termo in a case of acute pulmonary phthisis seems to be a new proof of the truth of the adage "Set a thief to catch a thief," since these experiments seem to show quite conclusively that the bacterium termo completely antagonises the bacillus of phthisis.

According to the *Centralblatt für die medicinischen Wissenschaften*, of July 18, 1885, quoted in the *Philadelphia Medical Times*, of August 8, a pure culture of bacterium termo was used diluted with gelatin and meat-broth, by means of a hand spray apparatus with double rubber bulb. "The expectoration rapidly decreased, until it ceased entirely during the last few days of the experiment. The tubercle bacilli likewise soon diminished from (in?) the expectoration, and did not reappear, while bacterium termo became more and more abundant." The fever decreased very much during the last few days of the experiment, and the bodily weight was decidedly increased; in short, the patient was very much better. We are not told why the administration of the bacteria of decomposition was discontinued—nor are we informed as to the aroma of the patient's breath after having undergone this novel therapeusis for a month, though that may be left to the imagination.

The *Times* says, regarding this experiment, that it "satisfies the requirements of science, and apparently establishes it as a fact that the antagonism known to exist between the bacterium termo and the bacillus tuberculosis, may be used for therapeutic purposes *cito, tuto et jucunde*." To our mind it also establishes another fact, not required by science, that the bacillus tuberculosis is somewhat particular as to the company it keeps. And however much we may hereafter dread that bacillus, we must respect it for its aristocratic sentiments. Before fully recognizing it as belonging to the upper classes however, it would be well to have some idea as to its behavior in the presence of Neisser's gonococcus and Lustgarten's bacillus, though this would not be an absolutely true index of its social standing, as these microbes move in the very best society.

The question which now arises is, Will the matter stop here, or is the time near at hand when the physician will relegate the prescription pad to the limbo of the forgotten, and make his daily rounds armed only with hand-spray apparatus with double rubber bulb, containing gelatin cultures of bacteria, labeled in proper order from abscess to zoster (and made by the improved process of some manufacturing chemist)? And if the usual number of "Physicians' Samples" are sent out, will not the doctor's office be somewhat more dangerous than a powder factory? The accidental introduction of the microbes of insomnia, into a foundling asylum, might be followed by most appalling consequences, unless the attendants were so fortunate as to be deaf. Far more dangerous than the doctor's office, however, will be the drug store (or, as it will then be called, the bacteria emporium), and it is quite probable that the manufacturing chemist will find it impossible to insure his life at any risk.

But perhaps there will now be a field of usefulness for the bacterial wealth which has been unused for several years and to which additions are being constantly made. It is not improbable that Seifert's bacillus of influenza, the bacillus of mumps, and several other seemingly superfluous microbes will come prominently forwards as candidates for therapeutic honors. It is quite probable, also, that we may be able to exchange with the lower animals for some of their bacteria. Is it not possible that the cholera bacillus may be made to do duty as a physiological antagonist to foot-rot in sheep, or that the bacillus of hog-cholera may find a field of usefulness in combatting the ravages of chicken pox? These are some of the questions almost necessarily suggested by Cantani's experiments. And it seems that when they are settled, the medical millenium will have certainly come—and cocaine will be cheap.

By referring to the abstract of Dr. S. K. Jackson's Address before the Medical Society of Virginia, (Journal of the American Medical Association, October 3, p. 375), it will be seen that this plan of treatment was first suggested by him in September, 1883, at the meeting of the Medical Society of Virginia.

THE AMMONIA TREATMENT OF TYPHOID FEVER.

In a paper read at the meeting of the American Medical Association, in 1884, Dr. S. K. Jackson called attention to a line of treatment which he claims "has furnished results very different from the recorded experience of others, a treatment suggested by the recognition of several pathological conditions, which, though long since demonstrated, had been entirely ignored by the profession when looking for indications for treatment." Dr. Jackson has recently treated the subject more fully in an article in the *Physician's Magazine*, August, 1885.

As is well known, one of the most prominent pathological states in typhoid fever is the excessive nitrogenous waste of the system—which need not be discussed further than to say that the probable causative factors are an inability to digest nitrogenous food, due to a deficiency of the digestive fluids in typhoid fever, and the enormous consumption of the nitrogenous matter of the system by what we may designate as the probable parasitic organism of the disease “That this microzoon is a nitrogen feeder, is evident from the fact that he lives and is enveloped in nitrogenous matters in urea and all nitrogenous excreta,” and further, “by the ammoniacal exhalations emitted by a typhoid fever patient, from the breath, the skin, as well as by the urine, which, when freely passed, as is known to all, emits the odor of ammonia

In the opinion of our author, then, the most important therapeutic indication is to supply this nitrogenous waste From the nature of the disease, however, this waste cannot be directly repaired by nitrogenous food, since, as has been shown, the glandular secretions which act on this food to render it digestible are at a stand still Even milk, the only natural food from which anything is to be expected, cannot be administered in sufficient quantities to supply the whole waste We must therefore make use of some highly nitrogenized substance, which does not require digestion, but which is easily absorbed when taken into the system This substance Dr Jackson believes to be *ammonia*, preferably in the form of the doubly nitrogenized salt nitrate of ammonia, since it also acts as a sedative, and, what is especially important, according to Dr Jackson, it has a remarkable power of reducing the temperature in typhoid fever Why or how it reduces the temperature of enteric fever cannot be definitely stated, but he thinks that “it is by inhibiting the life-processes of the microbe, by saturating it with the products of its own life, thus either crippling its vitality or altogether destroying its life, on the principle enunciated by me several years ago ‘No organism can exist in its own excretions, the product of its life processes’ Whatever may be its *modus operandi*, its effects are unquestionable”

The nitrate, however, is not the only salt of ammonia which may be used in typhoid fever The nitrate is an efficient antipyretic, the acetate, which combines well with acetate of lead, the most valuable astringent in these cases, is somewhat astringent, and “the nervous stage is wonderfully modified by the carbonate” and the hydrochlorate is undoubtedly the most efficient of all drugs in the stage of coma In these salts of ammonia, then, according to Dr Jackson, we have a complete armamentarium for the medical treatment of enteric fever at least, they are the main drugs to be depended upon, though turpentine is still acknowledged to be the most efficient remedy for meteorism, and acetate of lead, with acetate of ammonia, is to be administered in diarrhœa, though the acetate of ammonia alone may be sufficient It need scarcely be said that the preliminary treatment of these cases, until the true nature of the disease is manifested, is still the same The nitrate of ammonia may be given in doses of gr vj every two hours, combined, if necessary, with aconite and spirits of nitrous ether In diarrhœa the liquor ammoniæ acetatis may be given in doses of ʒj–ij every two hours, with or without turpentine or the lead salt When nervous symptoms supervene, carbonate of ammonia may be given in gr iij every hour or two, with an equal quantity of chlorate of potassium, and to this quinine may be added For the stage of coma the muriate may be given in gr iij doses, or more, every two hours, quinine being added if necessary

In connection with the above may be mentioned Dr Jackson’s system of feeding enteric fever patients So soon as the nature of the disease is apparent the patient is put upon an exclusive milk diet Animal broths are never given until convalescence is fairly established On account of the absence of the diastasic fluids, farinaceous or amylaceous foods are inadmissible, unless administered with a sufficient quantity of a reliable malt preparation, which would contain the amount of diastase necessary to convert the starch into dextrine and glucose Even when the salivary fluids return, and amylaceous foods are again administered more freely, the malt should be continued When the nervous stage or that of coma sets in, the diet may be more generous, and stimulants are admissible The results obtained by Dr Jackson are certainly sufficient ground for an extensive clinical study of his plan of treatment

IS CRANIOTOMY UPON THE LIVING FŒTUS EVER JUSTIFIABLE?

A distinguished teacher of obstetrics, residing in Boston, was recently visited by a delegation of Roman Catholic priests The priests were instructors in a large theological seminary The object of their visit was to obtain knowledge of the present status of the operation of craniotomy upon the living fœtus

Their attention had been called to the address of Dr S C Busey, before the Washington Obstetrical and Gynæcological Society, and published in the *American Journal of Obstetrics*, February, 1884 Dr Busey had unqualifiedly condemned craniotomy upon the living fœtus Modern scientific investigation supported the famous dogma of the Roman church, authoritatively proclaimed by the Theological Faculty (of Paris) many years ago,—“If it is not possible to extract the infant without killing it, it is not possible to extract it without committing mortal sin" The wisdom of the ancients was worthy of admiration

Certain members of the Faculty of the Boston Theological Seminary, although familiar with the responsible character of the *American Journal of Obstetrics*, desired corroboratory testimony Accordingly, they appealed to one of the instructors of the famous medical school of that city It seems scarcely necessary to add that the obstetrician denounced in very emphatic terms Dr Busey's paper as sensational and utterly fallacious

In the paper we have mentioned, the question, "Is Craniotomy upon the Living Fœtus a Justifiable Operation?" is discussed and decided in the negative in a manner that excited much surprise and positive displeasure when it was published General inaccuracy of statement, the omission of recent statistics, the frequent recurrence of logical fallacies in the premises, conclusions, and order of the argument at once condemned the essay in the eyes of the scientific medical world

Dr Theophilus Parvin, of Philadelphia, called attention to many glaring inaccuracies in an editorial, which appeared in the *Medical News*, March 29, 1884 Dr W W Jaggard, of Chicago, published a systematic criticism in the *American Journal of Obstetrics*, November, 1884 Dr Robert B Dixon, of Boston, read a paper upon the same subject, April 15, 1885, before the Section of Obstetrics and Gynæcology of the Suffolk District Medical Society, which was published in the *Boston Medical and Surgical Journal*, September 17, 1885 Dr Dixon's paper was ably discussed by Dr Benjamin Cushing, Dr A D Sinclair, Dr Fifield, Dr Reynolds, Dr Wm L Richardson, Dr Green, and Dr Lyman, who entirely agreed with the strictures upon Dr Busey's paper

Notwithstanding this accumulation of evidence, we find the errors inculcated by Dr Busey's sensational address still persisting, and liable to be perpetuated as an integral portion of the dogmatic theology of the Roman church

SOCIETY PROCEEDINGS

MEDICAL SOCIETY OF VIRGINIA

Sixteenth Annual Session, held September 15, 16 and 17, 1885

(Continued from page 355)

Evening Session,

The evening session was opened with a paper by Dr Bedford Brown, of Alexandria, Va, in continuation of the subject of *Scarlet Fever* A high temperature, a frequent pulse and excessive cervical adenitis must first claim attention He has seen some malignant cases with cold extremities and tongue with a body temperature of 107° Salicylic acid combined with tincture of aconite and infusion of digitalis diminish fever more decidedly than any other antipyretics He uses the following

℞

Acid Salicyl	ʒij
Tinct Aconit Radicis	gtt xij
Infus Digitalis	℥iss
Spts Ammon Arom	ʒiij
Syr Aurant Corticis	℥ss
Aquæ	℥i

M S Teaspoonful for a child 5 years old every three hours

This combination acts also as a diaphoretic, and favorably influences the kidney functions Its action may be increased by the tepid bath or wet pack He has observed marked benefit from alcoholic stimulants in malignant cases tending to collapse and coma, and in cases, on the other hand, of high fever, rapid pulse and extreme restlessness These agents also generally prevent adenitis In dangerous cases, the frequent use of baths is attended with exhaustion In scarlet fever, tending to extensive suppuration and pyæmia, tincture of iron Fowler's solution and quinia sulphate are the best agents To relieve acute nephritis and renal dropsy, enveloping the body with a flaxseed meal poultice, covered with oil silk answers well When the kidneys are engorged, the urine bloody, with dropsy of the chest and abdomen, a full dose of calomel followed by compound powder of jalap will often do good Such cases bear purgation better than almost any other But if the renal dropsy is attended with a cool skin, great pallor of complexion, feeble pulse and great general prostration, then frequent purgation is not well borne In such cases, use lumbar poultices, digitalis, acetate of potash and tartrate of iron and potash, with occasional saline cathartics There is a morbid element in scarlatina which often develops well marked rheumatism, hence the frequent cardiac complications When these threaten or occur, resort to the active agents named in the prescription above given The alkalies and salines should enter into the therapeusis of the renal complications Dr Brown has been disappointed with the diaphoretic action of pilocarpin in scarlet fever Iodide of potash is often a useful medicine in the nephritic sequelæ of scarlatina

Dr R I Hicks, of Casanova, Va, said he had treated a great number of cases of scarlet fever in his thirty years of practice, but had never seen anything denoting kinship between scarlet fever and diphtheria, nor had he seen scarlatinal throat complications threaten life Simple hot water throat mopping or gargling will relieve that He thinks the best plan of treatment consists in cold sponging of the body, and the use of quinine and of carbolate of iodine in small doses internally He lays great stress upon the surroundings of the patient under treatment Everything should be kept clean, and a current of fresh air should be kept up about the bed If the bed is behind the door, or in a corner of the room where there is no circulation of air, pull it out to the middle of the room, and keep the windows open When the weather is very cold, use rooms where there is an open fire place He believes that malignancy depends upon bad sanitation Zymotic germs do not live in pure air Filth breeds them He thinks salicylate of soda irritates the stomach too much, and corrosive sublimate in doses large enough to kill germs kills the patient

Dr Alex Harris, of Jeffersonton, Va , wished to emphasize (1) the benefit of isolation, both as a preventive and as a curative measure, (2) sick rooms with open fire-places, (3) position of bed out from the walls—not in a corner of the room and draughts of fresh air passing through the room The clothing of patient and bed should be changed daily He mentioned a striking case in which a patient almost in collapse was restored in a half hour from a suffocative condition to one of easy breathing, simply by clearing the room of everything except the bed, which was placed in the middle of the room, bedding and patients clothing changed, and currents of fresh air made to ventilate the room (4) Popular disinfectants are generally not useful in permissible doses Fire or water above 212° are germicides Hence, burn or boil whatever clothing has been used about the patient (5) Always disinfect a house in which a zymotic disease has been treated Scarlet fever has been traced to a house in which it was a year or more previous Pour boiling water all over the floors, in the cracks, on the walls, etc Doubtless steam would do better

Dr C T Lewis, of Clifton Forge, Va , said he knew of cases where one child had scarlet fever severely, and the other children were continuously with him yet without contracting the disease He believes in the stimulating plan of treatment, and thinks digitalis helps to relieve the swelling of the throat Sometimes he uses chlorate of potash and muriated tincture of iron He is a great advocate of such sanitary measures as Dr Harris has just named, and he feeds liberally

Dr John F Winn, of Richmond, agreed with the speakers as to their sanitary injunctions He thought that in towns particularly, placards should be placed on the doors of houses where there are cases of scarlet fever so as to warm off any who might innocently go into the house with the disease Again, funerals spread the disease He thought public funerals in all cases of death by zymotic disease should be prohibited by law In regard to the bedding, etc , use old cloths, etc , and as soon as removed or used, throw them in the fire The popular "disinfectant" solution of copperas is not a disinfectant, but is antiseptic Four ounces of chloride of lime dissolved in a gallon of water is a good preparation to pour upon the evacuations of typhoid patients Corrosive sublimate in solution is also used Let all articles to be used again be kept immersed in one or the other of these solutions for several hours To disinfect a room, burn from two to four pounds of common sulphur for a day in it, with closed doors The body, after death if to be moved, should be kept wrapped in cloths wet with Labarraque's solution, ℥iv to the gallon

Dr L Lankford, of Bowers, Va , also agreed with Dr Harris and Hicks as to fresh air in the treatment of scarlet fever, and thought malignancy would be rare if this was more insisted upon than it is As an illustration, he mentioned the cases of his two children The younger was kept down stairs in a warm room and malignancy developed, the other child was kept up stairs, where there was no fire, and where a window was kept open, and had no malignant symptom or sign The weather was cold

Honorary Fellow, Dr J Herbert Claiborne, of Petersburg, Va , spoke of a case in which the dermic inflammation was so intense that, on the third day, the skin came off in large patches all over the body Some children played day after day in the room with the patient, and yet none of them contracted the disease Shortly afterwards, some other children had the fever so mildly that they even went out of doors, and soon cases developed in their playmates An old lady living in the house with these mild cases had scarlet fever so badly that she came near dying To disinfect a sick room, not only the organic germs must be destroyed, but the spores also A solution of corrosive sublimate (1 1000) is required to kill the spores, or water at 280° But the best disinfectant for a sick room is pure fresh air, the doors and windows should be left open Of course, always disinfect articles of clothing, etc He thinks that Squibb's solution of chlorinated soda —℥ij to the gallon—is the most perfect insecticide in the market, and it is cheap enough to be in the reach of all

Dr Wm L Robinson, of Danville, Va , believes a great deal of good results from proper medicinal treatment He brings down the fever by using a full bath at 95° which he allows to cool down to 85° while the patient is in it Before taking him out of the bath, give a weak toddy, and rub the surface of the body over with camphorated oil He also depends much upon the free use of lithia water If the nose gets stopped up so as to cause mouth breathing, the child often wakes from cat naps with screams For this condition, he uses steam atomizer with chloral hydrate—two grains in an ounce of water This keeps the nose moist Large doses of calomel and jalap should be used if kidney complications supervene In one case of œdema of the lungs, pilocarpin hypodermically saved the patient

Dr Winn stated that a correspondent, in the Journal of the American Medical Association, places patients sick with diphtheria on house-tops or on the porches, and says that all get well The more fresh air, the better are the results of treatment

Dr W W Parker, of Richmond, Va , has often been disheartened at the results of treatment of scarlet fever Many cases get well, it is true, without any medical treatment, but formerly other cases did not get well under any plan of treatment Now he has good results, and he thinks the best remedy for bad cases is alcohol in free doses He wants his patients kept hot He got his suggestion from the good effects of alcohol in typhoid fever For the sore throat, applications of turpentine are as good as carbolic acid Keep the child in the house according to the weather In ten days in the summer, the patient may go out, but in winter, wait until three or four weeks have elapsed

Dr M A Wilson, of New River Depot, Va , has used Bartholow's prescription of tincture of belladonna to antagonize that condition of the throat which causes exudation, with great satisfaction

Dr Hugh T Nelson, of Charlottsville, Va , agreed with Dr Parker and others that many cases get well without any treatment He had known children without the eruption but with scarlatinal nephritis to spread the disease Hence, during an epidemic, keep children more or less separated from intercourse with each other Patients often succumb to accumulation of heat around the nerve centres, hence, the necessity for diaphoretics and heart stimulants After these use tonics The objects of treatment are to cause elimination of heat, and to quiet the heart

Dr Sam'l K Jackson, of Norfolk, Va , said that the common practice in his city is to use the chlorine treatment of Watson as described in his work on "Practice of Physic "

Mr J W Thomas Jr , of Norkfolk, Va , stated that Watson's chlorine mixture is as follows

℞

Potass chlorat	ʒij
Acid hydrochloric Aquæ	aa f ℥ij

M Keep in a dark bottle loosely stopped until effervescence had ceased Then

℞

Watson's chlorine mixture	ʒij
Water	f ℥iv

M Ten grains of chlorate of potash may be added if desired

Dr Robert S Lewis, of Culpeper, Va , has always used Watson's chlorine treatment with success

Dr Wm L Broaddus, of Newtown, Va , confirms the statements made about Watson's chlorine treatment He has used it especially in diphtheria, which, he thinks is related to scarlet fever Of eight cases in which he made tests, he used the chlorine treatment in seven cases, and they recovered, one case in which he used another plan of treatment died

Dr John Grammer, of Halifax C H , Va , uses Watson's chlorine treatment, and thinks well of it in scarlet fever It is important to attend to the secretions, and therefore he uses calomel and inunctions, which generally act promptly

Dr W D Cooper of Morrisville, Va testified to the value of the chlorine treatment—both internally and externally

Wednesday—Afternoon Session

Dr Hunter McGuire, of Richmond, exhibited a case of

COXALGIA, AMYLOID LIVER AND POTT'S DISEASE

The patient was a boy aged seven years Three years ago he had hip joint disease, and the head of the femur was removed by Dr L A Sayre, of New York Some carious bone was left, and the sinuses remained and continued to discharge When Dr McGuire first saw him the discharge amounted to eight to ten ounces of pus per day With this condition there were symptoms of amyloid degeneration of the liver The patient was put on bichloride of mercury, and the liver was diminished fully one half, so that there are some doubts as to whether there was any amyloid degeneration as this has hitherto been supposed to be an incurable condition The discharge from the sinuses at the hip joint amounts now to about ʒss of pus a day The most interesting feature of the case now is the fact that the patient has developed Pott's disease For three years this patient has been on his back, nursed most carefully and skilfully, with absolutely no chance for any injury to the spine, and yet he has developed Pott's disease solely from his hereditary constitutional vice, which completely disproves the teachings of some most eminent surgeons

Dr McGuire also exhibited a case of

OBSCURE PELVIC TUMOR—INFLAMMATORY EXUDATION, THREATENED SUPPURATION, OR SARCOMA?

The patient was a physician, Dr F , who, nine months ago, after becoming much exhausted, had symptoms of local peritonitis in the cæcal region the sequel to which was a lump in the left inguinal region, external to the bowel The patient suffers greatly from constipation, and from pain after an operation from the bowels

The tumor is now quite large, and by pressure on the iliac artery interferes with the circulation The outline of the tumor is easily made out along the crest of the ileum, while its lower border is at Poupart's ligament There have never been any signs of intestinal obstruction The patient has not the appearance of a person suffering from cancer, and there is no lympnatic involvement whatever in the inguinal or any other region, nor has the patient had any of the sharp lancinating pains of cancer There has never been any sign of intestinal obstruction It is possible that the tumor may be due to inflammatory exudation at the time of the local peritonitis, or it may be due to threatened suppuration, since Dr McGuire is certain that he has detected fluctuation, though two other surgeons have failed to detect it Should it not be one of these conditions it seems almost certain that it must be a sarcomatous growth

Dr M G Ellzey of Washington, D C , presented the

REPORT ON CHEMISTRY, MATERIA MEDICA AND THERAPEUTICS

He said that *Chemistry*, as a science, is approaching the exactness of completion As a practical art it is making rapid and brilliant advances The teaching of the elements of general chemistry should be relegated to the primary schools, in medical colleges medical chemistry as applied in practical medicine and surgery should be taught

In *Materia Medica and Therapeutics*, interest has recently centred around two drugs mainly, viz —cocaine and antipyrin Medical antipyretics have, however, proven slightly disappointing The evidence is a temperature may be reduced without benefitting the disorder, or even at times resulting in mischief The true place of *antipyrin* can scarcely yet be assigned Attempts to enrich materia medica by an attenuated cholera virus for inoculation have proven abortive Germs and germicides have continued to attract unabated interest The results of Dr Sternberg's studies, now before the public, are of much value Our germicidal doings have sometimes proven homicidal Eminent men have destroyed their patients with corrosive sublimate, but their eminence does not relieve them from criminal responsibility for these fatal poisonings Climatological therapeutics have been recently studied afresh Appalachian Virginia is a vast summer sanitarium The subject needs more complete study

Dr Smelt W Dickinson, of Marion, Chairman of the Section, presented the

REPORT ON ADVANCES IN OBSTETRICS, AND DISEASES OF WOMEN AND CHILDREN

As to *Antiseptic Midwifery*, he said, there can be no doubt that many lives have been saved by greater cleanliness since the agitation of this subject began Modifications of obstetric antiseptic rules of a year ago have been made, such as doing away with or lessening the frequency of vaginal and intra-uterine injections While mercuric bichloride is our best germicide, its use is more or less dangerous, especially when nephritis is suspected But antiseptic cleanliness of all things entering the puerperal vagina or womb—such as hands, sponges, instruments, etc —is all important Lying in chambers should be kept aseptic Cushings and other prophyctic systems are then described, first through bathing and then douching the vagina *ante-partum* with very weak solutions of corrosive sublimate, and then washing out the uterus with a like solution after delivery of the placenta or instrumental labor The doctor's and nurse's hands are kept asepticised all the time

Post partum drainage is best effected by letting the patient sit up on the chamber vessel when she wishes to urinate or have an action from the bowels, provided, of course, the condition of the patient permits it

The *contagium of puerperal fever* seems to be of a material character, capable of being acted upon, and either destroyed or washed away by vaginal or intra-uterine injections holding antiseptics in solution If the temperature rises above 100° after delivery, without other assignable cause, and the lochia become offensive, use antiseptic injections at once After the doctor has thoroughly disinfected himself, he may return immediately to obstetric or surgical work

Extra uterine pregnancy is now treated by electricity to kill the fœtus, with a subsequent resort to laparotomy to remove it

Combined version in placenta prævia consists in tamponing the vagina and anæthetize the patient After sufficient dilatability of the vagina is secured, remove tampon, introduce hand and carry two fingers into the cervix uteri Push fingers through the presenting placenta, draw the presenting part of the fœtus to one side, and at the same time let the other hand on the belly press from without so as to carry the buttocks down until a foot can be reached, draw the foot through the cervix so that the breech may act as a tampon on the lower segment of the uterus Then wait for the spontaneous expulsion of the child, or, at least, for sufficient dilatation of the cervix to complete delivery

As to *treatment of the cord*, Dr Christopher Tompkins, of Richmond, recommends that the cord be drawn between the fingers until some of the gelatinous matter is expressed, and then tie as usual, except a third ligament is applied near the one left on the umbilical cord Credé and Weber use absorbent cotton as a daily dressing for the cord instead of cloths, to prevent umbilical inflammation

Ethyl bromide promises well as an obstetric anæsthetic Cocaine is *sub judice*, with chances against its general adoption The forceps cannot be supplanted Abortion is generally advocated in dangerous placenta prævia, puerperal nephritis, and uncontrollable risky vomiting of pregnancy Well-regulated temperature of lying-in room is essential to the life especially of premature feeble children. Swinging as a substitute for artificial respiration is urged by some

As to *Diseases of Women, neurasthenia* is the most prominent A common error is the mistaking of nervous disease for womb disease Neurasthenia, according to Mitchell, is generally associated with anæmia, and is chiefly reflex in its manifestations. Rest, massage, electricity, and forced feeding are the essentials of treatment

Laceration of the cervix uteri will heal without an untoward symptom if blood-poisoning be prevented. Always treat the cellulitis before using any operative measures

Alexander's operation for backward uterine displacements consists in cutting over and down to the external inguinal ring, gathering up the ends of the round ligaments and drawing them sufficiently out to restore the womb to its normal position Then stitch the ligaments to the edge of the ring, and cut off about an inch of the end Drawing too much on the ligament has caused death Wear a pessary for two months after the operation Prolapse of both ovaries into Douglas' cul-de sac with consequent sterility, may be cured by this operation

Dr Goodell advises *rapid dilatation of the cervix for dysmenorrhœa* It is better than the cutting operation, especially for dysmenorrhœa of mechanical origin, as well as for nervous dysmenorrhœa

As to *Diseases of Children*, carbonate of ammonia in scarlet fever is gaining favor—large doses Dr R D Huffard, of Smythe Co, Va, uses the carbonate later in the disease, when the capillary circulation is languid Subnitrate of bismuth powdered over the sore tongue, which usually appears about the fifth day, acts well, as it does also in cancrum oris Trypsin as a solvent for diphtheritic membrane is a success Use it as a spray every fifteen minutes if the patient's strength will permit Chlorate of potassium is to be avoided in febrile affections where the blood is alkaline, and is condemned in diphtheria and in nephritic diseases causing scanty urine, uræmia, and the like *Icterus neonatorum* is supposed now to be due to the potency, to a greater or less extent, of the ductus venosus Dr Hartigan, of Washington, D C, supports the theory advanced in 1848 by Dr Marion Sims, that the *cause of trismus nascentium* is "an inward displacement of the occipital bone"

Thursday, September 17—Third Day

Dr R T Styll, of Richmond, presented the

TREASURER'S REPORT,

showing a balance in the treasury of $390 55 after all expenses are paid

A sum not exceeding $100 was voted to be used, if necessary, to retain legal counsel in case the State Board of Medical Examiners is sued, as threatened by a complainant who did not succeed in passing his examination before the Board

Dr W D Turner, of Fergusson's Wharf, from the Committee on Regulating the Practice of Pharmacy, reported favorably as to the petition for the enactment of a bill to regulate the practice of Pharmacy

Dr Bedford Brown, of Alexandria, read a paper on

THE SUCCESSFUL TREATMENT OF LACERATIONS AND FISSURES OF THE CERVIX UTERI OF LONG STANDING, WITHOUT SURGICAL OPERATION

(For an abstract of which see p 400)

Honorary Fellow, Dr George T Harrison, of New York City, then read a paper on

PUERPERAL SEPTICÆMIA, ESPECIALLY WITH REGARD TO PROPHYLAXIS AND ETIOLOGY

Due credit is given to the labors of Semmelweiss for his valuable investigations which pointed out the right road to the study of puerperal fever He showed that child-bed fever was a disease that comes from without Without a wound somewhere along the genital tract puerperal septicæmia does not exist After expulsion of the child and secundines in labor, the entire inner surface of the uterus is laid bare like a part of the skin deprived of its epidermis by a blister With this fact, it is only necessary to call to mind the possibility of very rapid absorption of septic matters introduced into the vagina or the uterus In primiparæ always, and in multiparæ generally, there are tears in the cervix, vagina or vulva, and often lacerations or contusions of the perineum, etc If a puerperal wound were protracted from external influences, it would heal like a wound on the surface of the body But putrefactive organisms can develop in the living organism wherever dead tissues or fluids (as extravasated blood) are found, while the healthy physiological tissue in general opposes a considerable resistance to their multiplication On the other hand, other pathogenic (disease generating) micro parasites find, in the living tissues within the cells, in the blood, in the lymph sinuses, etc, the most favorable condition for development and multiplication These fungi endowed with specific powers, are entirely different from the putrefactive organisms, and are destroyed by the latter In puerperal fever, the carriers of infection are either the pathogenous fungi, which generate traumatic diphtheritis, pyæmia and septicæmia, or they are putrefactive germs The latter are ubiquitous, the former are imported, and get to the puerperal woman by the hands, instruments, cloths, etc, that may be used about her genitals, They are derived from suppurating surgical wounds, cadaveric poisons and especially lochial discharges of women suffering with septic infection A minimum quantity infects in the most effective manner

The lochial discharges of puerperal sick *during an epidemic* are so infectious that they endanger life, by infection, of the non puerperal woman, of the pregnant, of physicians and gynæcological cases where operations have been performed In the puerperal woman, the conditions for the rapid development of the pathogenous fungi are most favorable Contrary to general opinion, Gusserow has shown that there is no connection between puerperal sepsis and erysipelas, and that the micrococci of erysipelas cannot produce pathological changes identical with septic processes The pathogenic fungi affect the organism immediately, while putrefactive germs do so indirectly by their influence on decomposable matters, always present in puerperal women An autogenous or autochthonous infection is an impossible thing The characteristic features of non pathogenous infection are (1) the late appearance of the fever, (2) the slight participation of the general condition, and (3) the existence of local morbid substrata

The principles of prophylactic treatment consist in pure air for the lying in woman, the careful avoidance of introduction of infectious matter into the genital passages, and the thorough disinfection of the genital tract The physician's and midwife's hands, instruments, etc, should be disinfected before using about a puerperal woman Disinfection must be both mechanical and chemical Use the finger nail brush, after thoroughly washing the hands with soft soap, and then wash the hands again Take off the coat and roll up shirt sleeves Then dip the hands and fore arms in a disinfectant solution Instruments and cloths should be dipped in such a 5 per cent solution of carbolic acid for several minutes During the pregnancy—especially if there be any puerperal fever epidemic—the woman should frequently wash her external genitals with soap and water and afterwards with boracic acid solutions When labor sets in, Dr Thomas advises her to use a warm vaginal injection of antiseptic character, but Dr Harrison protests against this injunction, under ordinary circumstances, as such injections are unnecessary and fraught with danger They remove the mucus which renders the vagina soft and pliable, and most of the disinfectants used, especially carbolic acid and mercuric bichloride, coagulate the mucus and irritate the surface of the vagina The bacteria naturally found in the vagina are not dangerous But if the patient has been subjected to the possibility of septic infection during the birth, then it would be eminently proper to use a copious antiseptic vaginal douche immediately after the birth and during the rest of the puerperal state In tedious and complicated labors, where frequent examinations have to be made or instruments used, injections are absolutely indicated Sometimes putrefictive decomposition of the uterine secretions occurs before labor ends In such cases, complete the labor as speedily as possible, and thoroughly disinfect the genital tract by intra uterine injections of carbolic acid or mercuric bichloride Wash the external genitals three or four times daily, and disinfect once a day by carbolic acid or mercuric chloride solution Close all lacerations of the perineum and vagina under strict antiseptic precautions, as by the continuous catgut suture Iodoform dusted over the raw surface favors union A powerful contraction and retraction of the uterus greatly helps in securing immunity from invasion of putrefactive bacteria, hence the value of Crede's method in expelling the placenta

Dr H Grey Latham, of Lynchburg, presented the

REPORT ON ADVANCES IN SURGERY

The report gave a running sketch of the discussion before the American Surgical Association on the "field and limitation of operative surgery of the human brain," disapproved of extirpation of the larynx and trachea, spoke favorably of drainage of the lung for gangrene, etc , and mentioned that laparotomies for many purposes are now established operations, as for strictures of the intestines, strangulations, excisions of organs non essential to life, etc Do not wait too long in strangulations of the bowels Operate as soon as diagnosis of strangulation is clear Operate as soon as vomiting sets in Cut down so as to get at the caecum If this is distended, the cause of obstruction is below, if it be collapsed or not tense, the obstruction is above If the strangulated coil of bowel is found to be gangrenous, the gut should be resected, and an artificial anus established When laparotomy is rejected, adopt Nelaton's operation of enterotomy, performed in the right iliac fossa Dr Latham lays down as propositions, 1st, that the best guide to the seat of an obstruction is not manual exploration, but visual examination, assisted, if necessary, by extrusion of the bowel, and, 2d, no case of operation for intestinal obstruction is properly concluded until over distended bowels are relieved of their contents

The latest *operations for hernia*, obliteration of the sac or closing the neck are the guiding points, and invagination has been laid aside or neglected *Digital dilatation of the pylorus* has been performed successfully for chronic non malignant stricture Make an incision in the stomach, introduce a finger through the opening and forcibly distend the stricture In *operative treatment of a rectal cancer*, the following are said to be reliable guides

1 If the finger cannot be passed beyond the disease, unless it is confined to the posterior wall, do not operate

2 The growth can be removed at a somewhat greater height when the disease is confined to the posterior wall

3 If when the finger has passed beyond the disease, the bowel is movable on the adjacent structure, generally speaking, the growth has not extended beyond the rectal walls and the case is suitable for operation, but if the bowel feels hard, rigid, and firmly bound to the surrounding organs, the case is unfavorable for an operation

4 Examine carefully the abdominal viscera, and if secondary deposits be suspected in the liver, no operation should be performed

Dr Rives Tatum, of Harrisonburg, Va , presented the report on

ADVANCES IN PRACTICE OF MEDICINE

He called attention to the prevalence of cholera in Spain, and to the methods of Dr Ferran for its prevention by inoculation His methods, however, had been pronounced uncertain, and did not prevent an attack of cholera Also that an attack of cholera did not prevent a subsequent attack The local anaesthetic cocaine, that has lately come into such great prominence as an alleviator of pain, was referred to, and its use in the treatment of coryza, hay fever, and fissured nipple, was specially mentioned Attention was called to the *ammonia treatment of typhoid fever*, as advocated by Dr S K Jackson, of Norfolk, Va Also to the mercurial treatment of typhoid fever and diphtheria, and the reduction of mortality in both diseases The *unity of tuberculosis and scrofula* was referred to, and the increase of the former and diminution of the latter trouble were dwelt upon Mention was also made of the exceeding rarity of idiopathic peritonitis, and it was said that peritonitis now is generally regarded as a symptom of some change of organic structure, and that its treatment should be prompt and radical In nervous troubles, attention was called to the curability of many obscure diseases heretofore thought to be incurable Eighty-five per cent of cases of locomotor ataxia are of syphilitic origin, and frequently curable

The report further called attention to the existence of sugar in the blood of carcinomatous patients, and peptone in sarcoma, and to the great aid these things will be in diagnosticating internal tumors

CLINICAL NOTES ON CARCINOMATOUS AFFECTIONS OF THE DIGESTIVE ORGANS—THE UNRELIABILITY OF GASTRIC SYMPTOMS AS EVIDENCES OF GASTRIC PATHOLOGY,

was the title of a paper by Dr R C Powell, of Alexandria, Va He first gave a description of carcinoma, *clinically considered*, and reported several cases showing the obscurity of diagnosis The cases illustrate two points of diagnostic importance (1), unreliability of gastric symptoms as evidences of gastric disease, and (2), the great value of cachexia as corroborative evidence of malignant disease Dr Powell regards the cachexia as a more certain sign of cancer than the presence of a tumor As to treatment, the indications are to sustain strength and to relieve pain A judicious selection of food is necessary if the stomach be involved Fatty, saccharine and starchy food are digested chiefly in the intestines, and these are best when the stomach is diseased If the pancreas is the diseased organ, give meats, albumenoid substances, milk, etc , which are digested in the stomach, but let all food be pancreatized before it is used If the liver is the diseased organ, allow both meat and fish, but not salted nor highly seasoned Salt water fish are believed to be best Fruit and vegetables—raw or cooked, as preferred—are allowable Permit "amusement without excitement, exercise without fatigue, and nutrition without stimulation" To relieve pain and procure sleep, use opium or morphia Fowler's solution, combined with bichloride of mercury, carbolic acid and tincture of iodine—one drop each—and bismuth subnitrate, are the commonly used medicines When bismuth is combined with atropia, it is useful in the salivation of cancer Cundurango and Chian turpentine have passed into oblivion, and alveloz will soon also be forgotten

Dr M A Rust, of Richmond, read a paper on

THE ETIOLOGY OF ZYMOTIC DISEASES

He commenced with the evolutionary history of bacteria from their discovery by Leeuwenhock, 1682, to the present time The germ theory was evolved from the fermentation theory—the morbid process of zymotic diseases being regarded as analogous to fermentation—the contagium playing the rôle of the leaven, exciting fermentation in the blood and humors of the body When Liebig appeared with his fascinating physico chemical fermentation theory, his application of it to explain the morbid process of zymotic diseases was generally accepted, and for a long time, *his* theory kept the yeast plant, which, since its first discovery by Leeuwenhock, had been repeatedly discovered, forgotten and rediscovered, in the background When, finally, mainly through the efforts of Pasteur, the yeast plant was universally recognized, the medical mind, dropping Liebig's theory, came to the conclusion that, if the active principle of fermentation be a living organism, the contagium of zymotic diseases must also be living matter Thus the germ theory was ready to spring into life, its way could never have been paved by practical medicine or clinical observations, the pathfinders were botanists, biologists, etc, who, by their researches and experimental studies concerning the etiology of certain epidemic diseases amongst plants and insects, disclosed in every instance, as incontrovertible and primary cause of the disease, the action of a low form of life Dr Rust then gave a detailed description of the silkworm plague and its stay by Pasteur It now stood clear before the minds of the young medical generation that similar organisms must be found as primary cause of the infectious diseases of mammalia, man included And they were found at first, perhaps, in too great redundance for the credit of the theory

Dr Rust divided microbes into three classes those which are undoubted, those of questionable character, and those whose existence is placed by induction and analogy almost beyond doubt The rapid progress made within the last decennium justifies the hope that all remaining obscurities as to the relation between microbes and disease will soon be elucidated After this, however, there still remain three perplexing questions

1st Whence come these numerous species of microbes? The view hitherto entertained, that microbes or germs are held in suspense by the air we inhale, or by the water we drink, Dr Rust thinks to be fallacious Any substance present in the air of a locality must have its source in the soil, or emanate from an object on the soil whence it is continually renewed, and what the water contains in solution or suspension is also derived from the surrounding soil or has found its way into it from without The soil, from the surface down to a considerable depth, is the habitat of the bacteria, whence they arise in the form of the finest dust Not from the streets of our overfilled cities (provided they are broad enough to give free access to sunshine) rises this dust, it rises from the soil into our crowded, unventilated houses as the smoke from the hearth is drawn up into the chimney No amount of sanitary measures hitherto devised will save a densely populated city from dying out in two or three generations (unless filled up by immigration), so long as the modern architect is allowed full sway Dr R discusses the various views advanced concerning the transmutability of bacteria—the change from the specific into the non-specific form and *vice versa*—and holds that our present state of knowledge admits neither affirmation nor denial

The second proposition is How does the morbid process of bacterial disease ever come to a happy end? Since the development of the germ theory we have arrived at the perception that we have to reckon with two factors—the cellular resisting power on the one hand, the degree of virulence and the numbers of the invading microbes on the other The numbers are of the greatest importance If a few microbes were sufficient to generate disease, what would happen to the doctors who are daily and hourly exposed to their onslaught? Infection or immunity, abortive or fully developed form of the disease, recovery or fatal end, are the resultants of the correlation between cellular resisting power and the intensity and numerosity of the invading microbes

But how shall we physiologically conceive this cellular resisting power? On this point we are still in the dark—a gleam of light is, however, dawning in the distance The white corpuscles, leucocytes or migratory cells, which circulate in the blood, are to be met with in every multi cellular organism, constituting the blood of the white-blooded animals, and being present in the tissues of the lower animals which have no vascular system—these leucocytes, identical with the amœba found in all stagnant waters, have formed the object of the particular studies made by Dr Metschnikoff, of Odessa He could only make his experiments on animals (bipinaria asteridæ, etc), which are of such exquisite transparency that all occurrences within the living animal can be accurately observed from without Just as we see the amœba eating under the microscope, Metschnikoff could observe through the transparent teguments of these animals the leucocytes eat up all foreign bodies It seems that by the division of labor in the multicellular organism, these leucocytes (which Metschnikoff has named phagocytes, eating cells) have assumed the task of eating up all heterogeneous and waste matter and eliminating what they cannot digest The question now arises whether the phagocytes, if they eat up all foreign bodies, could not likewise eat up intrusive microbes? The experiments hitherto made by Metschnikoff seem to answer us in the affirmative, and should these experiments and observations prove conclusive, recovery or fatal end of the disease will depend on the proportion between the number of the phagocytes and the number of the microbes. The impenetrable mystery of the cellular resisting power will have resolved itself into a prosaic, tangible eating power.

The third question is "How is immunity affected through vaccination?" There are numbers of untenable explanatory theories in the field. Instead of descanting upon them, as was his intention, Dr. R. refers to the exhaustive criticism of these theories by Dr. Sternberg, U. S. A., which appeared in the *London Lancet*, June, 1885. In his explanation of immunity, Dr. Sternberg rightly assigns the first rank to vital power—but the causative relation of vaccination to immunity still remains unexplained.

Will Metschnikoff's eating cells bring a solution? Minds prone to speculation might, even at this early hour, be led to advance the following theory: that the first meal of microbes eaten by the phagocytes may prove so acceptable that, in future, they will always be ready to consume any reasonable number of the same kind of microbes that may present themselves—and this theory would rest on foundations possibly more solid than those of any other theory concerning vaccination yet in the field.

Prof. M. L. James, of Richmond, read a paper entitled

DYSPEPSIA WITH NEURASTHENIA AND SOMNOLENCE.

He announced his purpose to make the paper brief and practical, and to write only from his personal observations. He noticed the fact that, although this morbid association was very often a serious inconvenience, and sometimes a grave disability, it had been comparatively little discussed in the literature of the profession. He referred to the fact that it sometimes seemed that neurasthenia might be a result simply of dyspepsia, in part from the interference with nutrition, and in part from a species of nervous shock, differing, of course, in degree from that described in surgery. Oftener, however, he said that it resulted from this condition associated with the nervous exhaustion, brought on by various causes, most frequently, perhaps, by severe mental efforts, watchings and anxiety; very often by the excesses of dissipation, over stimulation, excessive venery and masturbation. He referred to the fact that, while dyspepsia produced neurasthenia, that neurasthenia also aggravated the dyspepsia, and hence suggested that in treatment, the relations which they bore to each other should be constantly borne in mind; that it was a matter of prime importance for the relief of the dyspepsia that the forces of innervation should be maintained in the utmost possible vigor. That while digestion was a chemical process which might be accomplished in the retorts of the laboratory, it was also greatly influenced by the force of innervation, as has been demonstrated not only by experiments but by everyday observation.

He emphasized the importance of securing to the patient ample sleep as a means of fitting him to sustain the effort of digestion the succeeding day. While the province of his paper was not to go into the discussion of the various forms of indigestion and their special management, it was a proper consideration in the treatment of these cases that it should be considered by the physician, and the treatment and diet adapted to that end. That in all of these cases the diet should be that which is easiest of digestion, and at the same time afford an adequate amount of nutrition, especially in the form of phosphates. The phosphates of food are the best of the vitalized phosphates. An hour or two succeeding the morning's meal should be spent in pleasant mental occupation, scrupulously avoiding anything that could be considered positive mental effort, especially reading and writing, public discourse, or even close attention to such discourse. No laborious effort of mind or body ought to be taken until the process of digestion was well advanced, especially reading and writing, and in bad cases until nearly completed, and that no labor soould be sustained to the condition of positive fatigue.

He referred to dinner as the ordeal most trying in this morbid concatenation, and for that reason that the patient should be put under a certain sort of *training* for the effort of digestion for that meal. No sort of food ought to be taken between breakfast and dinner, and that a sufficient time ought to be allowed to elapse before partaking of dinner, to allow a complete digestion of the morning's meal with a period of rest to the digestive organs, and that the nervous system should be reinforced for the digestive effort at dinner by a period of recumbency lasting from half an hour to two hours, according to the severity of the case, previous to partaking of it, with sleep if procurable, which may be acquired easily by habit.

The articles of dinner also should be easy of digestion and nutritious generally, including a reasonable richness in the phosphates. That a period of relaxation should be taken after dinner with gentle mental occupation, and gentle exercise, preferably passive exercise in a carriage or on horse-back, until the process of digestion should be well advanced. He admonished particularly against the dangers of any active mental effort, including reading and writing, or public discourse. Supper should consist of lighter and more digestible articles of diet than the two preceding meals, and should not be taken until dinner was thoroughly digested and the stomach had had its period of rest, and that there should be entire abstinence from tea and coffee, as being likely to interfere with the coming night's sleep. He emphasized the fact that while medicines were necessary, some such regimen as that he had indicated was equally necessary. He also indicated that while such agents as caffeine would avert one of those oppressive spells after a meal, that pure stimulants were not suited for the cure, and for that reason that tonics, in combination with agents, which in more moderate doses had a stimulating effect, were the remedies to be used. Premising that digestion had been aided by pepsin and other digestive ferments, he said that alcoholic drinks in strictly stimulating doses were useful, but if carried a step beyond the condition of stimulation to the sedative influence was positively injurious He indicated the annexed formula as a convenient form of combining the remedies suited to these conditions, from which he had experienced the best of results

℞	Quiniæ phosphat	gr xvi	
	Strychniæ phosphat	gr 1/6	
	Acidi phosphoric (50 per cent)	m xx	
	Caffeine citrate	gr xii	
	Glycerin puræ		
	Spts vini rectificat	aa f℥ss	
	Tr cardamomi co	f℥j	M

S —One or two teaspoonfuls immediately before or after breakfast and dinner, to be repeated, if necessary, every hour or two till the nervous depression is relieved, or every half hour, till one or two doses are taken, if the depression be heavy

In such extreme cases where the powers of digestion were greatly enfeebled, he suggested the use of concentrated food in liquid form, and especially predigested foods, and in cases where the stomach was disordered to that extent that it would not tolerate such medication, that these remedies, especially in the forms of predigested food, should be administered by the rectum

(*To be concluded*)

CHICAGO MEDICAL SOCIETY

Stated Meeting, September 21, 1885

THE PRESIDENT, C T PARKES, M D , IN THE CHAIR

DR CHARLES F SINCLAIR read a paper on

SPECIAL VERSUS GENERAL STUDY IN MEDICINE

The medical profession, he thought, should look with favor upon the subdivision of medical work, because we see such vast accumulations of material in all the various departments of medicine that few would care to undertake, or have the ability, to even peruse our medical literature, much less master all the knowledge collected In this day of rapid interchange of thought, none can be found who can keep abreast of all the discoveries in the various departments of medicine Another reason for the existence of the specialist is the fact that very few men can secure the expensive instruments necessary to be used in the treatment of the various diseases, nor are there many physicians who could skilfully use them were they so fortunate as to possess them Many cases cannot be successfully treated without these instruments In our city, specialties should receive further development, because as they are clearly defined and faithfully adhered to in practice, proportionately does the city rank as a medical center

DR W F COLEMAN said that while he agreed with the author in the main points in his paper, he thought it should rest with each individual whether he shall confine himself to special practice or emphasize it in general practice It is advantageous to specialists that they should confine themselves to their chosen fields But we should not judge of the benefits to be derived from specialties by the individual success of each practitioner, but by the extent each practitioner enriched our literature by the record of his investigations It is thus that the eye and ear specialist, the specialist in throat and lung diseases, the laryngologist and others have done most to advance medicine

DR L T POTTER read a paper on

THE TREATMENT OF SYPHILIS

He said that the treatment of syphilis must be threefold—hygienic, tonic and specific By the latter is meant the administration of mercurial and iodine preparations The profession seems to be greatly divided in opinion in regard to the methods of using these remedies and the length of time they should be employed In scanning the literature on this subject, the reporter was surprised to find that those high in authority differed as to these points The reporter advanced two propositions first, that neither the iodine preparations alone, nor mercury alone, can always be relied upon as effective in the treatment of syphilis, but that *both* are necessary to eradicate the disease, second, that the duration of treatment must be at least two years, faithfully carried out, no matter how mild an attack In support of his first proposition, the reporter quoted Bartholow, Ringer, Jonathan Hutchinson, Keyes, Bumstead and Taylor as saying that mercury should be given in the primary and secondary stages of syphilis, and iodine of potassium in the tertiary stage They all agree that both must be used to effect what is called a cure In support of his second proposition, he quotes Van Buren and Keyes, Fournier, Bumstead and Taylor, as insisting upon the treatment extending over a course of two years or more Diday says the minimum time for treatment is twenty two months The two year course of treatment does not mean the continual administration of mercury or iodine, but at intervals the remedy may be discontinued for a short time, if it seems to have a debilitating effect on the patient In the light of such unanimity of opinion of eminent authorities upon this question of duration of treatment, it is surprising that intelligent physicians will positively assure their patients that they are *cured* of syphilis at the expiration of a course of treatment lasting from four to six months!! A physician who does so, is certainly criminally negligent Then it becomes all to impress upon patients the importance of carrying on the treatment for at least two years

DR E L HOLMES said that he considered the paper very valuable, because the author lays so much stress upon the importance of thorough and long-continued treatment One of the most important lessons he had ever received was to treat syphilis according to the plan the gentleman had advocated Many years ago he had been taught this lesson by sad experience It had been his lot to see many patients suffering from specific diseases of the eye long after they had been discharged by their physicians as cured He could not understand how any physician can believe it possible to cure syphilis without carrying out the treatment a long time In many years' practice in this city he cannot remember of having seen but three primary syphilitic lesions, and these all occurred on some portion of the eye He saw one man who had on the upper eyelid a sore which resembled and was treated as a burn, until its course decided it to be a chancre The man would not tell how he obtained it, but it readily disappeared under specific treatment A great many diseases of the eye occur thus, and the physician is unable to find out how they arise Many years ago it was taught that iodide of potash, if given in large doses, would effect a sure and speedy cure But Dr Holmes thought the treatment by large doses of iodide dangerous, as it ameliorates the symptoms so quickly as to cause the physician and patient to abandon the remedy too soon He thought it best to give the patient all the mercury he can bear in the primary and secondary stages Rub it in the skin and give it internally Follow this up eighteen months or two years, and then give iodide of potassium later Every three or four months give a course of treatment for years after You will have no trouble impressing upon intelligent people the importance of long-continued treatment

Dr R Tilley said he wished to refer to one point not touched in the paper, and that is, patients treated for syphilis are often told by their physicians of the importance of long continued treatment, but they will not heed these warnings and do not return This fact will excuse the physician many times, as it is not in his power to carry out the treatment when he wishes, and thus physicians should often be relieved of the blame of not having treated their patients long enough He did not think any intelligent physician would advocate treatment under two years, and he believed Keyes, in his last edition, extended the time of treatment to four years Dr Tilley was of the opinion that we cannot do without mercury, and yet some in high places teach this doctrine Those who try to treat syphilis without mercury are certainly responsible for later developments

Dr J Zeisler thought the present treatment of syphilis is not scientific, and that there had been little advance in this direction in the last century Cases are known in which, after seven years' treatment, symptoms of the disease returned Take the case of Prof Zeissl, who died last year He was infected while opening a bubo several years ago He certainly knew how to treat himself, and yet he died of cerebral syphilis This does not look as though the treatment of syphilis is yet founded on a scientific basis If the discovery of the bacillus of syphilis proves to be correct, it may prove the means of enabling us to treat syphilis scientifically

Dr G C Paoli said he is by nature a cosmopolitan, and always selects the best from the writings of all nations A great many books have been written on this subject, among which Ricord's stands first Ricord was a man of great talent, experience and powers of observation He had unexcelled opportunities for study in the Paris Hospital when he was the chief physician In regard to treatment, all agree that mercury must be administered for a long time There are syphilitic cases in which mercury is contraindicated, namely, phthisical patients and in albuminuria, unless we believe syphilis is the cause of the albuminuria

Dr R Tilley referred to one point introduced by Dr Zeisler, who referred to Professor Zeissl as having died of cerebral syphilis, claiming that no one would doubt Prof Zeissl's ability to cure syphilis But the question is not whether Prof Zeissl knew how to treat syphilis, but how did he treat himself? Cooper, in his book on syphilis, if he (Dr Tilley) were not greatly mistaken, cites Prof Zeissl as a type of those who used mercury sparingly If that is so, and Zeissl used it only sparingly on himself, then the death of Zeissl from cerebral syphilis is a very important lesson, and bears materially on the subject under discussion

Dr Zeisler said he knew that in the case of Prof Zeissl mercurial inunctions were made, but to what extent he was unable to say

Dr L T Potter closed the discussion by expressing himself as gratified at the amount of discussion which had been aroused, however, he was surprised at the statement that there had been little or no advancement in the treatment of syphilis In this day of elegant pharmaceutical preparations and easy administrations of mercurials and iodides, he thought there had been a great advancement, for pharmacy and chemistry have stepped in and given us preparations we did not use many years ago Mercury should not be given when it is producing a debilitating effect

The President, Dr C T Parkes, presented

A SPONGE REMOVED FROM A UTERUS

A short time ago he was called to see a lady who had been treated by a physician who introduced a sponge tent into the cervix uteri, and instructed the lady to allow it to remain two or three days, and then pull it out She attempted to do so, but the string broke and the sponge was not obtained After three weeks of suffering, with a discharge per vaginam, Dr Parkes was called to see her By digital examination he could not find any evidence of the sponge, the external os being closed so as to merely admit a probe But he could not find any sponge by probing, so he introduced an Ellinger dilator, and soon seized the sponge with a forceps and brought it out The symptoms present passed rapidly away, and the patient is now well The point to be learned is, that when a physician introduces a sponge tent, he himself should remove it

MISSISSIPPI VALLEY MEDICAL SOCIETY

(Formerly Tri-State)

Eleventh Annual Meeting, held in Evansville, Ind, Sept 8th, 9th, and 10th, 1885

(Concluded from page 390)

Dr Wm A Byrd, of Quincy, Ill read a paper on

TETANUS

(See page 399)

Dr Geo B Stewart, of St Louis, had used Fowler's solution in tetanus, but was unable to say whether it had been the means of cure or not He thought the pathology of the disease was very little known He reported a case of recovery from both trephining for injury to the skull and tetanus He agreed with

Dr Byrd that arsenic should be given in gradually increasing doses, as much as the patient can bear All the cases he has known to recover have done so under arsenic,

DR WM PORTER, of St Louis, reported a case of severe tetanic convulsions from a slight bruise on the finger, which had been covered with collodion Chloral was given but no arsenic used Recovery followed

DR G V WOOLEN, of Indianapolis, had found sponging the injury with a solution of chloral to act very well

SECOND DAY—AFTERNOON SESSION

DR G V WOOLEN, of Indianapolis, read a paper on

NASAL STENOSIS

The writer first called attention to the want of attention in former times to nasal disease, and the very great advance made towards a correct knowledge of it in the last ten years, thus accounting for want of correct appreciation by the profession at large which still exists He then briefly detailed the peculiarities of the anatomical construction of the nasal and accessory cavities, specially adapting them to the performance of their physiological functions, viz Olfaction, respiration, conduction of secretion to the pharynx, and as an accessary to articulated speech The title of the paper called attention only to a symptom of disease, but it and other symptoms often became of such importance as to demand attention as a disease

The chief causes are hypertrophy of turbinated bodies and mucous membranes, deviation of septum, adenoids, polypi, exostoses, and hypertrophied pharyngeal tonsils The degree of stenosis did not always denote the degree of disturbance, as is now well appreciated in the causation of hay fever The disturbances which follow were discussed under the following heads 1st Interference with the respiration act 2d With the natural flow of secretion 3d With speech and song 4th With olfaction It is difficult, in dealing with a given case, to determine which of these is the most important Intemperance with nasal breathing soon establishes disease of other parts of the respiratory organ by producing mouth breathing, a most dangerous practice, which often does not cease after removal of the cause

Attention was then called to the warming and moistening of the air and extraction of dust and other impurities in normal nasal breathing, most important functions, and when interrupted become etiological factors of disease of no small degree The law of catarrhal disease is that of descent, so that much that is supposed to originate in the lungs possibly does not, as one, if observant, is not long in noticing pharyngeal, laryngeal, bronchial and other such maladies disappear after the removal of obstructions higher up, especially nasal stenosis Attention was then called to defective drainage of secretions of nose, eye and accessory cavities The peculiar conformation of the nose is especially adapted to the drainage which was shown to be interfered with by any disturbance of the contour of the parts Evaporation and inspissation at once lead to clogging and dropping in pharynx of secretions, and their retention in the various cavities, giving origin to ozœna, and all of the direful results Without nasal breathing there can be no successful smelling, which function, being in the superior tract of the nose, is easily interrupted by stenosis Taste and smell are so intimately associated that their reciprocal functions depend upon that free passage way of the nose Good smelling and taste make eating one of the chief luxuries of life Our schools are full of children vainly trying to articulate successfully owing to enlarged nasal and pharyngeal tonsils The nose is an important resonance-chamber, and if by any cause obstruction occur, great modification in tone must ensue, and much that is supposed to be the result of faulty education and physical peculiarities is in fact the result of obstruction of this function

DR WM CHEATHAM, of Louisville, said that he thought Dr Woolen had failed to refer in his paper to nasal stenosis as a cause of asthma and hay fever It is now a well known fact that one of the principal factors in the production of hay fever is situated in the nose, and often depends secondarily upon nasal stenosis There are three factors which must be present to produce hay fever "an external irritant," as pollen, etc, "a predisposition on the part of the system to become influenced by this irritant," and "a vulnerable or sensitive area through which the system becomes influenced by the irritant" Since these three factors have been recognized, "hay fever," which to this time was considered among the incurable diseases, now is among the most readily relieved The sensitive areas are located in the region of the distribution of the spheno palatine ganglion, that is, on the inferior and middle turbinated bones and the pharynx That these sensitive areas are so situated is proved by their irritation by means of a probe By this means all the symptoms of "hay fever" can be produced, and by the destruction of these areas by means of acids and caustics hay fever is cured, also that by anæsthetizing these areas by means of the muriate of cocaine, all the symptoms of hay fever are relieved "I do not care how much stenosis we may have, we must have the sensitive areas before we can have hay fever"

DR WM PORTER, of St Louis, read a paper on

SOME ERRORS IN PHYSICAL DIAGNOSIS

(See page 345, Vol V, No 13, this JOURNAL)

DR ARCHIBALD DIXON, of Henderson, Ky, read a paper on

PROGRESS IN MEDICINE

A review of the history of medicine during the past year will show that solid advances have been made in methods of treatment, remedies of value have been added and the usefulness of older ones confirmed The introduction of cocaine as a local anæsthetic, had nothing more been done, would mark this as a year ever to be remembered by our profession

The great question now is, is cholera a preventable disease, and if so, can it be kept from our land? There is no doubt that each and every visitation has been the result of importation Now the point to be determined is, is the germ origin of the disease the true one? Is the germ always present in cholera? Is it ever present elsewhere? Koch maintains that there is a definite organism associated with cholera, and this opinion is supported by many of the best men of our profession both in this country and in Europe After discussing the bacillus question in all its phases, he thought that it followed that the poison of cholera must be a micro organism, for nothing but a living thing could reproduce itself, and he considers that Koch's position, so far, has remained unassailable If, then, the germ theory of cholera be true, and it be a contagious and portable disease, then, as a matter of course, it must be admitted that it is a preventable disease, and the point at once arises, how can we most easily destroy these germs? The answer is, by disinfection and the proper use of germicides, with a sufficient quarantine to guarantee detention until this process is complete Detention without disinfection is not effective With the efficacy of germicides, quarantine should become what it is intended to be, not a delusion and a snare There is no better plan presented than that of Joseph Holt,[1] M D , President of the Louisiana State Board of Health, which the doctor presented in his paper Perhaps in New Orleans, whose people have been so often scourged, these precautions of Dr Holt will be carried out, but not elsewhere Dr Rauch,[2] Secretary of the State Board of Health of Illinois, says that if no vessel were allowed to leave a port infected with cholera or carrying persons or things from an infected region, without being first made secure against the possibility of carrying the disease, it would of itself render unnecessary all other means of combating cholera, so far as we are concerned But this has never been accomplished During the existence of Asiatic cholera in Europe this country is only safe when a system of sanitary supervision is practised over the immigrant and his effects The instructions of our best sanitarians, if carefully heeded, will demonstrate that cholera can be kept from our country The Royal Italian Society of Hygiene has arrived at conclusions which, owing to their experience with the cholera during the past year, are worthy of receiving great consideration

Evening Session

Dr N M Baskett, of Moberly, Mo , read the history of a case of

PISTOL SHOT WOUND OF THE MOUTH

It was from a 32 calibre revolver, and occurred in a young mulatto woman The ball entered on the inside of the mouth, about the junction of the ramus of the inferior maxillary with the body of the bone, and extended slightly inwards and markedly downwards, barely missing the tongue, piercing the pillars of the fauces near the right tonsil, and losing itself in the muscles of the neck The probe passed inwards and downwards, and indicated a course which would have brought the ball to the surface on the back, at a point midway on a straight line drawn from the spinous processes of the first dorsal vertebra to the middle of the spine of the scapula But the probe did not pass one half the distance from the ramus of the jaw to the point indicated, and, as the bullet could not be felt, it was evident that its course must have changed At the point of the shoulder was another wound, extending upward and inward directly towards the line which the other wound would have made, had the course of the bullet continued The patient was positive that the wound in the left shoulder was made first and by the first shot fired, and the wound in the mouth made by the third shot The second shot had missed her entirely

There was but little hæmorrhage from either wound, and the woman suffered but little from shock Probing the wound of the left shoulder indicated that the bullet was probably located near the left of the spinous process of the first dorsal vertebra, and was not considered dangerous

The wound in the mouth had evidently been made while the mouth was open, as there was no external wound We had, then, a wound covered by the masseter, and other facial muscles, in the first part of its course, and the ramus and body of the inferior body of the inferior maxillary In the second part of its course, the fascia, muscles and vessels of the infra-maxillary space, and thirdly, in the neck, where the course of the bullet was lost, it was covered by the integuments, fascia, sterno cleido mastoid, and omo-hyoid muscles, and in close relation to the important blood-vessels and nerves of that region The wound was cleansed, opium administered, and for the first few days the woman did well Fever, not excessive, presented itself, and the wound suppurated and discharged greatly It was syringed out twice daily with an antiseptic solution The patient's condition was considered fairly good up to the day of her death

On the evening of the seventh day hæmorrhage occurred, and considerable blood was lost before it could be checked by the use of various astringents, styptics and coagulants She was much prostrated In about an hour the hæmorrhage returned, and in spite of all efforts to check it she expired in about five minutes

The autopsy showed that the muscles of the neck along the course of the wound were in an inflamed and almost gangrenous condition The secretion of pus was enormous, and of a very unhealthy character Dark bloody clots of decomposed blood existed along the course of the wound in close proximity to the blood vessels, which appeared to be inflamed It seemed that hæmorrhage had occurred from the facial artery close to its origin with the carotid The bullet which produced the wound was found resting on the first rib close to its junction with the vertebra The bullet which entered at the point of the left shoulder was found lying close to the spinous process of the first dorsal vertebra, as we had anticipated

The remarkable features of this case are 1 The location of the principal wound, 2 The absence of marked shock, 3 The inflamed condition of the great blood-vessels of the neck revealed by the autopsy, 4 The extensive infiltration of the muscular tissues with pus, and the absence of any symptom of pyæmia up to the time of death

---

[1] Review of Quarantine and Maritime Sanitation by Joseph Holt M D New Orleans 1885

[2] North American Review August 1885

Dr S C Charlton, of Seymour, Ind , discussed the question

IS THERE A TYPHO MALARIAL FEVER?

He does not propose to definitely answer the question, but to give some reasons for believing in the prevalence of such a fever to a large extent throughout the Western and South-Western States Since the publication of Dr J J Woodward's report, in 1862, of a fever which prevailed in the U S A, which, after careful study, he denominated as typho-malarial, there has been much controversy in regard to the accuracy of the name In large cities there is much decaying organic, and in the country much decaying vegetable matter, which is the cause of malarial disease, but never the cause of specific infectious disease But when the spores of infectious disease are introduced into the system, already under the influence of malaria, they as certainly produce the phenomena of typho malarial fever as the "pathogenic spores" of the various infectious diseases will produce their special disorders, or the specific poison of typhoid fever will produce that disease Accepting this view with regard to septic poison, we can readily understand why hydrant water containing septic matter may develope typho malarial fever, as was the case in Evansville four years ago

All writers admit the strong analogy between typhoid and typho malarial fever namely diarrhœa, tympanites and iliac tenderness The symptoms become more or less marked during the second week of the disease The characteristic eruption of the typhoid fever may be observed Low delirium, deafness, subsultus tendinum, etc , occur more frequently, earlier, and are more marked than with the simple remittent Enlargement or suppuration of one or both parotids are sometimes noticed The forming stage is longer than in simple remittent The fever is longer and its gravity greater Perforation of the intestine is liable to occur Bronchitis and pneumonia are frequently developed Convalescence is more protracted In some cases the phenomena of typhoid fever and of periodical fever are intermingled, in varying proportions, in some the periodical, in others the typhoid phenomena predominating Cases of typho malarial fever occur in most if not all malarial regions, which shows that the special cause of typhoid fever is not held in abeyance by the presence of malaria The extinction of malaria is followed by cases of unmixed typhoid fever, as if the latter followed in the wake of the former Dr Flint says, that typho malarial fever is caused by the combination of malarial and the special causes of typhoid fever It has been said that remittent fever becomes converted into typhoid fever This is not accurate There is not a metamorphosis of the one disease into the other, but a combination of both diseases The changes which take place in the blood in typho malarial fever, so far as we are able to determine, are similar to those which occur in typhoid fever, combined with those which are characteristic of malarial fever

The published literature on typho malarial fever is scarce, Drs Flint and Loomis being the only two authors who have gone into the question thoroughly, and they do not agree as to its etiology In the writer's opinion, Dr Loomis is correct, and if the name "typho malarial fever" is not correct, he would suggest that we call it septic remittent Typho malarial fever is not characterized by the typical course observed in typhoid, but varies as the septic or malarial poison predominates It is generally ushered in by a distinct chill, and in some instances without premonitory symptoms This is followed by a high temperature, varying from 103° to 104°, and a pulse of 100 It is frequently noticed that the pulse becomes slower during the second and third weeks, falling from 100 down to sixty, so that we sometimes have a comparatively slow pulse, throughout the course of the disease, and sometimes with a temperature of 103° the pulse beat will not exceed sixty or seventy Another point in this connection is that if the special cause of typoid fever is necessary to the development of the typho malarial fever, why is it that we have a hundred cases of typho malarial fever in a few months, and not a single case of well-marked typhoid, as was the case in Seymour during the past year? It may be that the presence of malaria is sufficiently potent to hold this special cause, whatever it may be, in abeyance

In conclusion, he said that he was satisfied with the name, typho malaria, as the most appropriate for this form of fever, and until future study shall give a word more expressive of that disease, he will cling to it and treat the disease accordingly

Dr Amos Sawyer, of Hillsboro, Ill , read a paper on *The Relation of Mind to Matter,* Dr H J B Wright, of Olney, Ill , a paper on *Three Cases of Nervous Disease, with Special Reference to Pathology,* and Dr James H Letcher, of Henderson, Ky , a paper on *Cat-Gut Ligatures*

THE ADVISORY COMMITTEE

appointed on the previous day, after several meetings, made the following recommendation

1st That the organization by sections be dispensed with,

2d That a Committee on Programme, consisting of three, be appointed by the Chair,

3d That the next meeting be held the second Tuesday in July, 1886,

4th That papers alternate, medicine, surgery, obstetrics,

5th That book matter, generally known, be omitted from the papers,

6th That new things be presented,

7 That greater brevity be practiced,

8th That more patients and specimens be presented Adopted

The President appointed the following

COMMITTEE ON PROGRAMME

Drs G V Woolen, of Indianapolis, Amos Sawyer, of Hillsboro, Ill , and Wm Porter, of St Louis

The Committee on Nominations reported the following

OFFICERS FOR THE ENSUING YEAR

President, Dr Arch Dixon, of Henderson, Ky , 1st V Pres't, Dr G W Burton, of Mitchell, Ind , 2d V Pres't, Dr T D Washburn, of Hillsboro, Ill , 3d V Pres't, Dr Wm Cheatham, of Louisville, Ky , Secretary, Dr H J B Wright, of Olney, Ill , Treasurer, Dr F J Lutz, of St Louis, Mo

Adjourned to meet at Quincy, Ill , the second Tuesday in July, 1886

FOREIGN CORRESPONDENCE

BRITISH ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE

The fifty-ninth session of this Association met this year for the second time in the Granite City of Scotland—Aberdeen Nineteen years ago was held its session here under the Presidency of the Prince Consort This year Sir Lyon Playfair presided, and read his address on Wednesday evening to an audience of about 3,000, gathered in the Music Hall, complimenting in the very highest terms last year's meeting at Montreal His paper was lengthy, taking in a wide range of practical thought He maintained, and gave figures in proof, that England was behind several other nations in appropriating funds for educational and scientific purposes, and referred warmly to Washington's farewell address as salutary advice on the importance of popular and scientific education —quoting his language The convention is divided into eight Sections, the mention of which will give an idea of the scope of study 1 A—Mathematical and Physical Sciences, 2 B—Chemical, 3 C—Geology, 4 D—Biology, 5 E—Geography, 6 F—Economic Science and Statistics, 7 G—Mechanical, 8 H—Anthropology

Prof McIntosh, as chairman of the Biological Section, in his opening address reviewed the subject of *Phosphorescence of Marine Animals,* dwelling upon the Nactiluca of the protozoa family, which he said was but "a gelatinous sphere" spreading its luminosity at times over large areas of the sea Nor did he neglect the crustacea and molluscs as phosphorescent generators, and thought, no doubt, this power enabled the inhabitants of the dark depths of the sea to see their way without the light of the sun He also alluded to the firefly and other luminous species, but did not venture an opinion upon the *modus causandi*—saying that was unknown to scientists

The history and comparative anatomy of the Fay whale—Megaptera Longimana—was ably and interestingly discussed by Dr Struthers, Professor of Anatomy in the Aberdeen University Prof Fowler maintained that the whale was derived from a four-footed land animal

Sir John Lubbock's subject was *Insect Instinct,* choosing the ant and the bee for study and illustration He thought it was curious that if a strange ant were mixed with a nest of 500,000 it would be recognized by every one at once almost, and dealt with as an intruder and enemy He thought the recognition was due to scent rather than to sight or feeling He had kept some queen bees under observation twelve years, and though their eggs were sterile, still ovation went on, and their joints were reasonably supple yet

Dr J McGregor-Robinson entertained the Section for more than half an hour, giving an ocular demonstration, by means of a complex apparatus, of the *Direct Action of Anæsthesia on a Frog's Heart* The frog's heart was suspended in a proper medium, and kept beating, each pulsation moving an indicator, which registered the variations, and was visible to the entire audience I asked the doctor to furnish me a statement of results as to the difference of effects of chloroform and ether, which is kindly given as follows

A marked quantitative difference was shown between the different anæsthetics used, as exhibited in the following tables which show the stimulating, reducing and paralyzing effects of the anæsthetics on the heart

	Stimulating	Reducing	Paralyzing
Ether	1 per cent	1$^1/$ per cent	2 per cent
Ethydine bichloride	$^1/_{0}$ " "	$^1/_{10}$ " "	$^1/_{[illegible]}$ " "
Ethyl bromide	$^1/_{0}$ " "	$^1/_{8}$ " "	$^1/_{4}$ " "
Chloroform	$^1/_{30}$ " "	$^1/_{0}$ " "	$^1/_{10}$ " "

A qualitative difference was also shown Ether and ethydine very much resemble each other The relaxation after each contraction was complete with chloroform and bromide of ethyl, though a marked difference was shown, the heart exhibited a great tendency to contract spasmodically around the canula So marked was this that it was difficult to pass fluid through the heart so as to wash out the drugged fluid This action was never observed after the heart had been fairly under the influence of ether and ethydine It was noticed in more than one case that the heart became spasmodically contracted around the canula immediately after receiving the first stimulating dose of the drug This occurred with ether as well as with chloroform With ether, however, it rapidly passes off, and does not recur after the influence of the anæsthetic is felt It did not so readily pass off in the case of chloroform Might not such action account for some deaths under the use of chloroform before any great quantity of the drug has been administered? The heart recovered speedily from the influence of ether, but slowly from chloroform Ether was found not to be cumulative, but that could not be said so decidedly of chloroform

Prof McCormick, on the subject of the *Action of Cold on Microphites,* said that cold and freezing only arrested development, but that *heat* would sterilize all fluids Referred to Coleman's method of freezing meat, 129° F , for transportation to distant destinations, and explained the curious methods of cultivating microbes Recurring then to the subject he said "Experiments discourage any practical hope of destroying microphites by cold Freeze paste and the water is crystallized, but the coloidal matter remains, so that on admitting heat again the water returns to its normal condition, the microbe, therefore, does not crystallize, but remains in waiting for warmth to restore it to its normal condition" Instances the similar condition of the frozen frog In this way life may be arrested and inertness maintained in a moderate way for almost any length of time, with complete restoration when returned to proper environments A rabbit had been restored, after being rigid, under a temperature of 150° F, for one hour and a half It has been demonstrated by these experiments that a temperature lower than that of any meteorological observation had been induced, and yet vitality restored by the application of heat

The museums and laboratories here are quite extensive, giving ample advantages, but hotel accommodations are altogether inadequate for such large bodies, for all are overcrowded, and lodgings are generally taken, so that even these are difficult to obtain A B T

Sept 12, 1885

MISCELLANEOUS

NEPHROLITHOTOMY —MR VICTOR HORSLEY removed a calculus weighing two and a quarter ounces from the kidney of a woman on September 16 There had been symptoms of renal calculus for four years Since the operation the urine, which was fœtid before, has become normal, and the whole of the operation wound, with the exception of the track of the drainage tube, healed by first intention within five days

THE FLOATING WASH HOUSES OF PARIS are to be suppressed in consequence of a report drawn up by Engineer to the Seine Navigation Bureau, they being considered dangerous to the health of the city

STATISTICS ON INSANITY —The International Congress of Physicians engaged in the cure of mental diseases was recently held in Antwerp The scope of the Congress comprises the bases of good international statistics concerning the mentally diseased, and the relations between criminality and mental disease The Congress has appointed an international committee to determine the headings for the bases of statistics regarding mental diseases

DR EDWARD O SHAKESPEARE has been appointed by the United States Government to go to Europe for the purpose of investigating the cholera The appointment reflects great credit on the Government

A CONGRESS OF RUSSIAN ALIENIST PHYSICIANS will be held in February, 1886

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT U S ARMY, FROM SEPTEMBER 26 1885, TO OCTOBER 2 1885

Col T A McParlin, Surgeon, directed to transfer his duties and the public funds for which he is accountable, as Asst Medical Purveyor, to Capt Henry Johnson, Medical Storekeeper, who will, in addition to his present duties, temporarily perform the duties of Asst Medical Purveyor, New York City (S O 223, A G O, Sept 29 1885)

Maj D G Caldwell, Surgeon, ordered from Ft Laramie, Wyo, to Ft D A Russell, Wyo (S O 97, Dept Platte, Sept 25, 1885)

Capt G W Adair, Asst Surgeon, granted leave of absence for one month, with permission to apply for one month's extension (S O 104, Dept Dak, Sept 18, 1885)

Capt Louis Buchmin, Asst Surgeon, ordered from Ft D A Russell, Wyo, to Ft Laramie, Wyo S O 97, Dept Platte, Sept 25, 1885)

First Lieut Geo F Bushnell, Asst Surgeon, ordered from Dept Dak to Dept East (S O 219, A G O, Sept 28, 1885)

First Lieut C N B Macauley, Asst Surgeon, relieved from duty at Ft A Lincoln, D T, and ordered for duty at Camp Poplar River, M T

First Lieut Wm L Knudler, Asst Surgeon, when relieved from duty at Camp Poplar River, M T, by Asst Surgeon Macauley, to report to commanding officer Ft Snelling, Minn, for duty (S O 105, Dept Dak, Sept 21, 1885)

First Lieut P G Wales, Asst Surgeon, relieved from temporary duty at Boise Bks, and ordered for duty at Ft Cœur d'Alene, Idaho S O 160, Dept Col, Sept 21, 1885)

First Lieut C B Ewing Asst Surgeon, ordered from duty at Ft Stanton, N M, and ordered for duty at Ft Leavenworth, Kan (S O 147, Dept Mo, Sept 25, 1885)

OFFICIAL LIST OF CHANGES IN THE MEDICAL CORPS OF THE U S NAVY DURING THE WEEK ENDING OCTOBER 3 1885

Surgeon William H Jones, to Navy Yard, League Island, Pa, Oct 15, as the relief of Medical Inspector M Bradley

Medical Inspector Michael Bradley, detached from Navy Yard, League Island, Pa, Oct 15, and placed on waiting orders

Asst Surgeon Thomas Owens, to Naval Station, New London, Conn, as the relief of Surgeon Wm A Corwin

Surgeon Wm A Corwin, detached from Naval Station, New London, Conn, and ordered to the U S Str "Adams," Oct 31

Surgeon A C Magruder, ordered to the U S Str "Yantic," without delay, as the relief of Surgeon H L Law

Surgeon H L Law, detached from the U S Str "Yantic," and wait orders

Surgeon W J Simon, detached from the Naval Academy, Oct 1, and wait orders

Surgeon M C Drennan, detached from the Naval Academy, Oct 1, and wait orders

P A Surgeon Arthur G Cabell, to the U S Str "Adams, Oct 31

OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF MEDICAL OFFICERS OF THE U S MARINE HOSPITAL SERVICE FOR THE THREE WEEKS ENDED OCTOBER 3 1885

Austin H W, Surgeon, to proceed to Burlington, Vermont, on special duty Sept 23, 1885

Bailhache, P H, Surgeon, detailed as chairman of Board for the physical examination of officers of the Revenue Marine Service Sept 28, 1885

Vansant, John, Surgeon, order to New Orleans, La, revoked, to proceed to St Louis, Mo, Oct 2, 1885

Purviance, George, Surgeon, to proceed to Louisville, Ky, as inspector Oct 1, 1885

Gossaway J M, Surgeon, detailed as chairman of Board for the physical examination of officers of the Revenue Marine Service Oct 3, 1885

Godfrey, John, Surgeon, order of Sept 16 amended, to proceed without delay to Louisville, Ky Sept 28, 1885

Goldsborough, C B, Passed Asst Surgeon, order of Sept 16 amended, when relieved, to proceed to Chicago, Ill Oct 1, 1885

Irwin, Fairfax, Passed Asst Surgeon, detailed as recorder of Board for the physical examination of officers of the Revenue Marine Service Sept 28, 1885 To examine physically, and instruct crews of the Life Saving Service, Third District, in the method of restoring the apparently drowned Oct 3 1885

Banks, C L, Passed Asst Surgeon, detailed as recorder of Board for the physical examination of officers of the Revenue Marine Service Oct 3, 1885

ORIGINAL LECTURES.

METHODS OF RESORPTION AND DISPOSAL OF FOREIGN BODIES IN THE LIVING SYSTEM[1]

BY N S DAVIS, JR, A M, M D,
LECTURER ON PATHOLOGY IN THE CHICAGO MEDICAL COLLEGE

Materials to be reabsorbed are chiefly the products of inflammation, such as exudates and necrosed tissue These constitute foreign bodies, or are unnatural in the place in which they are found They are therefore disposed of as are all foreign bodies, by an attempt on the part of the system to rid itself of their presence

Substances capable of resorption differ in their nature, and may be grouped in three categories first, liquids, second, soluble solids, and third, insoluble solids By soluble solids I mean those that can be dissolved in the normal juices of the tissues, the lymph or blood

Liquids are readily removed, unless they exist in overwhelming amounts, by the lymphatics The liquid mingles with and practically becomes part of the lymph, and therefore is disposed of with it The foreign liquid becomes more and more diluted by admixture with fresh lymph the further it passes from its original seat, until it becomes evenly distributed as a part of the whole blood and interstitial liquid of the body If an irritant, it loses its effect in proportion as it is diluted This dilution too takes place more rapidly when the foreign liquid is irritant, as inflammation is excited, and with it a more or less copious serous exudate Thus the irritant effects are confined and weakened, so that the noxious material may be eliminated The irritant may, however, exist in such quantities that the system is unable to remove it

Exudates which are to be reabsorbed are not thus irritating, but are capable of being removed unless they are so great, as they are in some dropsies, that they mechanically prevent or obstruct the lymphatic circulation The latter is dependent upon the action of the voluntary muscles, which by their contraction, as it were, squeeze the lymph out of and through them The muscles, when surrounded by an excess of fluid, are able to act very imperfectly, if at all Another factor that maintains the lymphatic circulation is the aspirating property of the thoracic cavity upon the great vessels within it But in œdema, when exudates exist in excess in the tissues, the respiratory acts are almost always impeded and imperfect A third factor which contributes to render resorption impossible under these circumstances is the condition of the blood-vascular system, which is usually such that it rather tends to increase the exudate instead of contributing to maintain lymphatic circulation

Foreign bodies which are soluble in the interstitial fluids are rapidly surrounded and bathed by an unusual quantity of them It seems to be a law of the animal economy to attempt at once the removal of all unnatural bodies, or at least a disposal of them so that they will not irritate the surrounding parts The first step in the disposal of them is uniformly the production of a copious serous exudate This enables a soluble body to be dissolved and removed in liquid form, through the lymph channels Bodies which are thus soluble are to a greater or less extent irritating They are always sufficiently so to excite a copious exudation of serum from the blood, and may be sufficiently so to cause violent inflammation

Of the bodies that are insoluble in the interstitial fluids we recognize two kinds those that are perfectly insoluble, and those that are capable of being liquefied in the living tissues They are also more or less irritating Consequently they too excite changes which tend to their removal or to render them inert In order to comprehend the methods by which they are disposed of, let us examine two or three illustrative cases If a solid, insoluble, smooth and compact body like a ball of glass be inserted into the tissues, an inflammation is lighted up around it Exudation of both serum and leucocytes takes place from the neighboring vessels As the serum is unable to dissolve the glass, it is gradually reabsorbed The leucocytes, however, attach themselves to the surface and form a complete shield or covering By their own multiplication and by additions from the blood, a more or less thick layer of these cells surrounds the foreign body and separates it from the surrounding tissue Under these circumstances they develop first into granulation tissue, and subsequently into cicatricial or fibrous tissue, which ultimately forms a complete envelope about the ball, and thus renders inert the irritating power of the foreign body The abnormal substance is now *encapsuled* This process constitutes the first step by which insoluble substances are disposed of

If the foreign body be a granular mass, as, for example, small pieces of charcoal, a lump of pigment granules, or numerous fine pieces of stone, the method is very different The first steps in the process are the same, but the subsequent ones differ much First, as before, a serous exudate is provoked, which contains many or few leucocytes These latter, as in the former case, at once attack the granular mass Instead, however, of developing on its surface into granulations and ultimately fibrous tissue, they seize upon each granule, and by their amœboid movements surround and inclose the granules within the protoplasm of their own substance When this is done, the leucocytes are slowly washed away from the foreign body into the lymph stream and are carried along in its course The granules are thus one by one transported away, and more or less scattered through the body, and perhaps ultimately eliminated from it That the leucocytes have this power is well known, for not infrequently they can be seen in microscopic specimens to contain fragments of pigment Thus tattoo marks are sometimes partially destroyed, the pigment being removed from its original seat and deposited in a neighboring lymphatic gland Thus, also, the pigment particles which we inhale are carried to and deposited in the bronchial lymphatic glands Experimentally, too, it has been shown that these corpuscles have the power of taking up and transporting granular matter If to white corpuscles that are under examination on the warm-stage of a microscope a little very finely precipitated carmine is added, the most active corpuscles will at once be seen to first adhere to the particle of coloring matter, and then by degrees to change its position so that the pigment is within the corpuscle, in other words, the living protoplasm apparently flows around the carmine particle The corpuscle has also the power to disengorge its load and to leave it On this account, often, particles of foreign substances may be transported in the living body through many stages by different corpuscles

---

[1] Abstract of a Lecture delivered before the class in Pathology at the Chicago Medical College in November, 1884

When the leucocytes gather around such a foreign mass, they are not content to attack the exterior only, but press into every crevice and penetrate the interior through its interstices Thus these masses often become honeycombed If the material be of considerable size, and in portions quite compact, after partial removal has occurred by this process, a slow encapsuling may occur which will cut short or interfere with further attempts at removal

A third variety of substances insoluble in the interstitial liquids comprises such as are liquefied under the influence of the living body As a type of these we may take coagulated albumen, which is insoluble in blood or lymph How this liquefaction is accomplished is not absolutely known Many writers leave the question "how?" unanswered, and even unasked, contenting themselves with the statement of the fact of liquefaction Others mention the fact without special discussion, but in such connection that we might think that they believed the removal of the foreign body occurred not by liquefaction, but by the transportation of its particles little by little by the leucocytes, as has just been described for insoluble granular matter By others it has been suggested that liquefaction was due to the presence of some unorganized ferment in the tissues or interstitial liquid We must admit the possibility of such a ferment being present, though none has yet been isolated or experimentally proved Unorganized ferments usually act readily when separated from the living body But liquefaction of albumen will not take place in the tissues if they are not alive, nor in lymph nor blood when these are removed from the living body The element of life in the surrounding substances we are led to believe plays an important part in the process of liquefaction

If we reject the theory of the presence of an unorganized ferment, we must naturally look for another explanation We have seen that the white corpuscle plays an active part in the resorption of granular bodies, and I would ask, May it not also be the active agent of liquefaction, acting, however, in a very different manner from a transporting or carrying agent? In order that unicellular animals may support life, they have the power of assimilating food with which they come in contact For example, the amœba swallows, or rather encloses, particles of food in its protoplasm, when the little mass apparently melts away, becoming a part of the homogeneous substance of the animal The lowest plants act in almost the same way They, however, absorb the substances on which or within which they are planted without first swallowing them as solid particles Many bacteria are known to cause liquefaction of their solid foods merely by their contact with them For example, when planted upon culture gelatine, as the bacteria grow, they become surrounded by liquid, which is contained in hollows in the gelatine made by its own liquefaction

We have already seen that the leucocyte or white corpuscle possesses the property of taking up and transporting granular matter as may an amœba In other respects, also, it bears a close resemblance to these monads It has the power of locomotion, of projecting prolongations of its protoplasm, of retracting them, of throwing out others from another side, in other words, at times will show as well developed pseudopodia as the amœba

Is it not, then, probable that it has other homologous properties? It must be nourished, as well as all other portions of the living body We ordinarily suppose that this nourishment exists ready for assimilation in the blood and lymph However, as in other respects it bears so strong a resemblance to unicellular animals, it seems at least quite probable that it may have the power of liquefying or causing solid particles to slowly melt away as they do when they are appropriate food for and when they are being taken up by the amœba Nor is it necessary to suppose that solid materials which can thus be liquefied must first be taken up as granules within the mass of the leucocytes, for the latter may be able to act as do some of the bacteria, simply by contact with the liquefiable substance The facts that life is necessary to the process of liquefaction and that the leucocytes exist during the process about the liquefying body in undue numbers would make it possible to suppose that these leucocytes were the vital agent which produced the dissolution of the insoluble mass Liquefaction would thus be due to the assimilative and metabolic changes of the leucocytes. It would be a process of digestion on the part of the leucocyte. The liquefied body having been utilized as food by the white blood cell, which would play the part of an organized ferment.

This explanation of liquefaction I have not yet seen given elsewhere, but arguing, as students of nature must constantly do, from analogy, it seems most plausible and most probable. If true, however, the word liquefaction may not be altogether appropriate, the process not being necessarily one by which substances are liquefied, but rather one by which they are assimilated. We may therefore say that certain insoluble foreign bodies are removed by assimilation. This process is of common occurrence in the animal body. By its help it is that dead tissues are separated from living, that sloughs are formed upon free surfaces, that animal ligatures disappear when imbedded in the tissues, and that solid inflammatory products are removed.

A line of demarcation around a sloughing surface is a line of inflammation. The latter process causes, by the necessary exudation, a separation of the cells from one another, and their death and final liquefaction. Thus a severance of continuity occurs between the living and dead tissue. In the case of ligatures, the ordinary process of absorption takes place. Enough irritation occurs to cause at least a slight exudation of serum and a more abundant migration of leucocytes around the ligature. Then follows liquefaction and disintegration. Deep seated inflammation often occurs, accompanied by destruction, necrosis of tissue, which finally disappears without discharging on a free surface. The necrosed cells are broken up, liquefied, and absorbed or assimilated.

Not unfrequently foreign bodies are observable which, though insoluble in the interstitial liquids, cannot be grouped under either of the three varieties just described. They may present in part the characters of each, and therefore we find them often honeycombed by the disintegrating, liquefying and transporting agency of lymph and cells, and also later on encapsuled. All the methods of resorption may have been active, and finally the mass made non-irritating by encapsulement.

These are, in brief and in general terms, the changes effected and methods employed by nature in removing and rendering inert foreign bodies.

Since the above lecture was given, I have found in the *Revue des Sciences Medicales*, for January, 1885, abstracts of two articles by Metschnikoff, which were originally published in *Rouskia Medicina*, in 1884, in which views similar to those stated above are advanced in regard to the power of white corpuscles to, by "intracellular digestion," cause certain substances to disappear. As arguments in favor of this view, Metschnikoff cites the changes observable in the tail of the tadpole while it is atrophying or being absorbed. From the beginning of the process a collection of amœboid cells is observable, which contain entire particles of nerve fibres and primitive muscle fibres. The cells gather about the caudal muscle, surround little by little the primitive muscle fibres, and finally devour them. Similar changes are observable also during the metamorphosis of echinoderms and other invertebrates. In these latter the mesodermic cells play the part that in vertebrates is taken by the white blood cells.

Metschnikoff also extends the theory, and because in certain septic diseases he finds bacteria in the white corpuscles, believes that the latter are the agents which nature has provided for the removal of these as well as other foreign and noxious substances from the body.

ORIGINAL ARTICLES

PRACTICAL REMARKS AND SUGGESTIONS IN REGARD TO DISEASES OF THE EAR, THROAT AND NOSE.[1]

BY JOSEPH A. WHITE, M.D.,

SENIOR SURGEON TO THE RICHMOND, VA., EYE, EAR AND THROAT INFIRMARY.

The frequency of aural, throat and nasal affections, the necessity of early attention to them to prevent lamentable consequences, and the prevalence of certain errors in regard to them, were the excuses for this paper. In reference to aural trouble, for example, there is not sufficient importance attached to their relation to general medicine, and when ear symptoms develop during the course of some constitutional trouble, such as struma, syphilis, gout, tuberculosis, the exanthemata and zymotic diseases, and during dentition, these symptoms are frequently ignored, as requiring no special treatment, and if the patient call the attention of the physician to them he is often told that with the restoration of the general health the symptoms will disappear. The reader doubted, in view of the frequency with which these cases come into the hands of the specialist, if this advice be warranted by clinical experience.

The dependence of the ear upon the throat, and the very frequent occurrence of acute or chronic ear trouble with impaired hearing resulting from nasal or throat disease, is now a recognized fact, but at the same time the error of supposing that the cure of the *cause* will remove the *effect* is too common. Such mistaken advice misleads the patient, who is actively treating the nose or throat trouble, into a sense of security which nearly always ends in disappointment. There is no class of cases which more requires early and active local treatment, or in which delay, from procrastination or improper advice, is so disastrous in results as in diseases of the ear, whether from constitutional or local causes, or propagated from the throat. This is particularly the case when children are the patients, it being so often said that they will *grow out* of the trouble.

He then referred more particularly to the disastrous consequences of neglecting middle ear catarrh, whether suppurative or not, in its earlier stages. In suppurative inflammation neglect may be fatal both to hearing and to life, from whatever cause it may result. Sometimes this trouble commences with great pain, or, again, the discharge from the ear may be the first intimation of the trouble *Pain* should be combatted by local leeching, warm applications (hot water, warm cloths, but no poultices), a twenty per cent solution of cocaine,[1] with sulphate of atropia locally, and anodynes internally In this exudative stage, the muriate of pilocarpine[2] and sulphide of calcium should be administered If, in spite of this treatment, pain persist, and examination of the membrana tympana shows it to be bulging, an incision should be made into its posterior inferior quadrant, so as to evacuate the contents of the tympanum with the air bag When the discharge has once begun, whether with or without acute symptoms, the ear should be kept clean with a carbolized or borated solution of bicarbonate of soda, and by the daily use of Politzer's air bag to keep the Eustachian tube free Should the pain still persist the cocaine solution, without any atropia (which would be dangerous after the perforation of the drum head), should be continued The drum may also be dusted with pulverized boracic acid once or twice daily Such treatment is within the reach of every physician, and if neglected the results will be unfortunate in the large majority of cases, as mastoid disease, meningitis, embolism, thrombosis, cerebral abscess, pyemia, etc , may result Where one case recovers without treatment a dozen lose their hearing by gradual destruction or distortion of the ear structures, and the younger the case the more lamentable the consequences In nearly every case of suppurative inflammation of the middle ear, the membrane limitans of the mastoid cells and mastoid antrum undergoes more or less pathological alteration Threatening mastoid complication can be frequently averted or aborted by leeching and by the administration of sulphide of calcium If there be pain or pressure, or redness over the process, a free incision to the bone should be made, and should pain still persist the bone should be opened

---

[1] Read before the Medical Society of Virginia, Sept. 17, 1885.

In scarlet fever, a most fruitful cause of suppurative ear disease, we sometimes see cases in which hearing is totally lost This is especially so in those cases in which the throat trouble is worst, sometimes with the formation of diphtheritic membrane—the so called scarlatinal diphtheria In some cases the destructive tendency of the inflammation involves the membranes of the labyrinthine windows, thus emptying the labyrinth of its fluid contents, and destroying the nerve filaments, resulting in absolute and permanent deafness In other cases the labyrinth seems to participate in the exudative tendency, and nerve-perception is temporarily obliterated, gradually returning as the exudation is absorbed

In the same relation of ear diseases to general medicine, the reader called attention to the influence of menstruation, both at puberty and at the menopause, upon such troubles At the climacteric period it is very common to find impaired hearing coming on, usually in the form of adhesive middle ear catarrh The reader has seen cases of otorrhœa coming on at puberty with each menstrual period, yield readily to treatment, and return with each menstrual period, with a bloody purulent discharge

In using the aural syringe for removal of impacted wax Dr White advocates only a gentle flow of the liquid He is much opposed to forcible injections, as by them the drum-head may be considerably congested or damaged For the removal of impacted wax he uses frequent applications of a warm solution of bicarbonate of soda in glycerine and water, until the wax becomes softened and partially dissolved, when it is easily removed by gently syringing Foreign bodies may be removed by a gentle flow of warm water as easily as by force In some cases it is necessary to use the ear probe, but this should only be attempted with good illumination with a head mirror

Dr White then referred to the prevalence of erroneous impressions regarding some throat and nose troubles, such as confounding follicular tonsillitis with diphtheria In *tonsillitis* we have fever, sometimes nausea, dysphagia, throat pain usually beginning on the third day, and exudation in patches on the surface of the swollen tonsil In *diphtheria*, with the same symptoms, the exudation is not confined to the tonsil, but extends over neighboring parts Guaiacum seems to be a specific for the follicular tonsillitis, and supports the view that tonsillitis is more common in rheumatic persons When recurrent attacks are common, or when the tonsil becomes so hypertrophied as to cause defective nasal breathing or impaired articulation, the tonsils should be removed Anything that interferes with free nasal breathing, and necessitates mouth breathing, should be removed Many cases of fever in childhood are due to an unlooked for and unknown tonsillitis There are also various reflex disturbances which are due to obstruction to nasal respiration, as reflex cough, sick headache, asthma, and hay fever Treatment of the nasal trouble will sometimes cure these affections, even the hay fever

CLIMATIC RELATIONS OF CANCER AND CONSUMPTION

BY EDMUND ANDREWS, M D , LL D ,

OF CHICAGO ILLINOIS

Some years ago, I showed by a comparison of the United States statistics of mortality for the censuses of 1860 and 1870, that cancer had a distinct climatic relation, being most abundant in the same regions as consumption [1] The law of prevalence for our country appears to be, that both diseases are most abundant on the sea coast, and diminish as we recede to the interior, and that at equal distances from the sea they are more abundant at the north than at the south

In preparing the Census Report of 1880, Surgeon J S Billings has given great attention to the tabulation of the statistics of mortality in such a form as to show the influence of a variety of conditions upon disease, and prominently among them the effects of

---

[1] In spite of assertions to the contrary Dr White has conclusively shown that cocaine anæsthetizes the *membrana tympani* as shown by the fact that he has performed paracentesis of the apparently healthy *drum head* after the application of cocaine without pain to the patient

[2] Except in certain cases of heart trouble in which pilocarpine is contra indicated

[1] Chicago Med Exam p 178 1872

climate In the Report now being issued, he has subdivided the States into parts, such as seashore regions, mountain regions, great river belts, regions of the northern lakes, etc , and combined these segments into twenty-one "grand groups," showing the mortality of different diseases in each group This arrangement gives a much superior opportunity to trace climatic effects than the former division by States Taking the twenty one "grand groups" in successive order, I have calculated for each the proportion of deaths from cancer and consumption to the total deaths from all causes, showing clearly the relative frequency of these diseases in each section, and placed the results in the following table

Table showing the proportions of deaths from cancer and from consumption to deaths from all causes in the year 1880

No of Grand Group	Names and Descriptions of Grand Groups	Proportion of Deaths from Consumption to Deaths from all Causes	Proportion of Deaths from Cancer to Deaths from all Causes
1	North Atlantic Region or New England Sea coast Belt	1 to 6	1 to 36
2	Middle Atlantic Coast Region or Sea coast Belt from New York to Virginia inclusive	1 7	1 " 51
3	South Atlantic Coast Region or Sea coast Belt from North Carolina to Georgia inclusive	1 11	1 111
4	Gulf Atlantic Coast Region or Sea coast Belt from Florida to Texas inclusive	1 8	1 57
5	North eastern Hills and Plateaus or Inland Hill Regions of New England and Eastern New York	1 " 5½	1 32
6	Central Appalachian Region or Allegheny Mountains from New York to Maryland inclusive	1 9	1 " 47
7	Region of the Great Northern Lakes	1 " 9	1 49
8	Interior Plateau or the Plateau between the Appalachians and the Atlantic Coast Belt extending from New York to N Carolina inclusive	1 7	1 " 47
9	South Central Apalachian Region or the Mountains from Virginia to Alabama inclusive	1 8	1 " 66
10	Ohio River Belt	1 7	1 " 58
11	South Interior Plateau or the Inland Level Regions of South Carolina Georgia Alabama and Tennessee	1 12	1 " 97
12	South Miss River Belt	1 11½	1 166
13	North Miss River Belt	1 9¼	1 52
14	South west Central Region or those parts of Missouri Arkansas Louisiana and Texas lying north of the Gulf Coast Region and west of the S Miss River Belt	1 15	1 147
15	Central Region of Plains and Prairies or that Belt of Ohio Indiana Kentucky and Tennessee lying next west of the Mountains	1 7	1 " 65
16	Prairie Region or parts of Missouri Iowa Illinois Kansas Nebraska Wisconsin Minnesota and Dakota	1 " 10	1 73
17	Missouri River Belt (as far as to upper border of Dakota)	1 10	1 100
18	Western Plains or level portions of Dakota Montana Wyoming Nebraska Kansas Colorado New Mexico and of N W Texas	1 14	1 265
19	Heavily Timbered Region of the North west or the Forest portions of Michigan Wisconsin and Minnesota	1 7½	1 " 42
20	Cordilleran Region or the Great Central Mountain Belt of the West extending from Canada to Mexico	1 13	1 " 112
21	Pacific Coast Region	1 7	1 42
		1 to 9 23	1 to 76 9

In preparing this table, I have disregarded the minor fractions Broad principles only can be deduced from it, because the government, in taking the census of mortality, cannot attain minute precision in all details Examining first the two columns of figures, we see at a glance that cancer and consumption, though presenting minor variations, have in the main the same topographical and climatic distribution, in short, that cancer abounds in the same climates as consumption In two former articles I showed this fact from the censuses of 1860 and of 1870 The law regulating this distribution may be expressed nearly as follows

1 Cancer and consumption abound most on the sea-coast belts

2 At the same distance from the sea, they are abundant at the north, and less so at the south

For instance, New England, which is far north and skirts the sea, has one death from consumption to about six deaths from all causes and of cancer about one to thirty six Going westward to the region around the great lakes, we find consumption one to nine and cancer one to forty nine Still further west the prairie region shows consumption one to ten and cancer one to seventy-three On the same latitude the great western mountains and plains show consumption about one to twelve and cancer one to about 150 Now if we descend to the sea coast of Oregon and Washington Territory, the ocean influences again prevail, and deaths from consumption rise to one in seven and one-half, and from cancer to one in sixty-six Everywhere the same result will be found It is not clear which of all the possible influences of the sea produces these diseases One can imagine it to be the prevalent dampness, the salt spray in the air, the modifications of temperature, the use of sea food, or the presence of specific bacilli bred by the ocean, or requiring sea air for their ready development The figures in the Census Report do not enable us to solve this chaos of problems

The effect of latitude is not as distinct as that of proximity to the sea, yet there is a general diminution of both diseases as we go southward We find as follows

	Consumption	Cancer
New England Coast	1 to 6	1 to 36
Middle Atlantic Coast	1 to 7	1 to 51
South Atlantic Coast	1 to 11	1 to 111
Florida	1 to 12	1 to 105

In the three successive censuses New Mexico has shown itself preeminent for its exemption from both cancer and consumption No portion of the United States approaches it in this respect In the census of 1880, out of 2,436 deaths from all causes, only forty-nine were from consumption and thirteen from cancer, giving the following ratio, viz

Consumption	1 to 50
Cancer	1 to 187

Surgeon Billings divides most of the Territory into the eastern or plain portion, and the western, or the mountain part, the latter being traversed by the valley of the Rio Grande, and the former by the Atchison, Topeka and Santa Fé Railway The eastern or plain part is, according to the figures, superior to the mountain part in exemption from these two diseases, but both are above any other State or Territory in immunity New Mexico combines the two conditions which in this country secure protection from the diseases under consideration, viz remoteness from the sea and southern latitude The elevation is from 4,000 to 8,000 feet above the sea The winters are mild and dry and the rainfall slight, being from ten to fifteen inches a year The little rain that falls comes mostly in summer showers On the whole, it would seem well proved that New Mexico is the proper residence for consumptive patients Colorado has also stood deservedly high in these respects, but the figures in the census have been made to appear less favorable than those of ten years ago, in consequence of the really large number of consumptives who have been taken thither in the advanced stages of the disease

The question is often asked, "Do cancer and consumption on the whole increase in the community?" The following figures convey the substance of what is known on the subject They are obtained by averaging the ratio of all the States and Territories for the only three censuses which have recorded any mortality statistics

Table showing the Proportion of Deaths from Cancer and Consumption to Deaths from all Causes in the whole United States in 1860, 1870 and 1880

	1860	1870	1880
Ratio of deaths from Cancer to deaths from all causes	1 to 142	1 to 101	1 to 77
Ratio of deaths from Consumption to deaths from all causes	1 to 11	1 to 9	1 to 9

Apparently cancer has nearly doubled since 1860 Consumption, on the other hand, increased largely to 1870, and since then has remained nearly stationary, showing a slight decrease in 1880 In the New England States consumption shows a very decided diminution This may be from improved modes of living and from the immigration into the towns of foreigners, not yet brought under the influence of the climate

Inferences about the increase or diminution of these diseases are subject to possible error, because the tables of mortality do not represent the whole decennial periods, but only the single years 1860, 1870, and 1880 It may be that there are yearly variations of irregular character, which would present a different aspect could we eliminate them by averaging the whole of each ten-year group together Still, the general tendency of the figures as they now stand is to show an increase of the ratio of these diseases

CONSEQUENCES OF ACUTE AURAL TROUBLES IN CHILDREN WHEN NOT PROPERLY ATTENDED TO[1]

BY T E MURRELL, M D,

OF LITTLE ROCK ARK

In examining many persons one is struck with the varying degrees of hearing power in different individuals, and in different ears of the same individual So much so is this the case that it has been extremely puzzling to fix a standard of hearing power, even ough the character of the test be agreed on, which [illegible] a difficult problem But, to meet all pe- [illegible] will presume the various methods in [illegible] tried on each person under test, and a comparative estimate deducted therefrom In this manner there is found a very great difference even in persons of presumably normal condition—persons who have no catarrhal affection and no history of ear disease If one selects for his examination persons beyond middle life he will find few whose hearing reaches the highest standard Causes arising in the course of life from climate, mode of living, habits and vocation, lead to defective hearing, not to mention acute affections incident to exposure, general diseases, and accident

Omitting all causes arising after childhood, we will only consider acute affections in children as causative of dulness of hearing in after life

Many persons with impaired hearing who can give no history of their trouble, have likely suffered from some middle ear affection in infancy or early childhood, a period of life in which records of disease are readily lost In proof of which statement, a careful inspection of the drum-membranes of such persons will often reveal evidences of former trouble In childhood nearly all diseases are acute primarily, to which affections of special organs are not exceptions The two diseases of the ear most frequent in infancy and early childhood are acute catarrh and acute suppuration of the middle ear Not only the mother, but also the physician, is quite liable to overlook an ear-ache in an infant The cause of its plaint is unsuspected in the search for the more common pains and distresses of this time of life By reason of, or in spite of, expectant remedies, the sufferer assumes its usual playfulness in a few hours, or days, and all goes well until another such attack comes on at some indefinite future period These attacks may repeatedly recur—being often of a sub-acute type—before the cause is ascertained During one of the attacks a careful inspection of the fauces would reveal a redness with, perhaps, œdema, and of the drum-membrane, an injection along the handle of the malleus or a uniform redness When the attack has passed away no vestiges of it may remain, either in hearing power or appearance of the parts involved But should they be often repeated the mucous membrane of the pharynx and middle ear gradually assume abnormal conditions, the lymphatics become engorged, the tissues pervaded with formative elements, the arterioles enlarged and capillaries congested, and the functions of the parts altogether disturbed If the perturbating causes are now removed, there is a tendency to restoration to a healthy condition, but often a vulnerability remains, whereby the slightest exciting cause, as a cold in the head, is sufficient to renew the morbid processes It is fortunate that all acute and sub acute catarrhs of the middle ear in infancy and early childhood do not, from neglect, terminate in injury of a permanent character Enough do, however, to warrant particular stress on the importance of proper attention being given them, notwithstanding the popular idea of their unimportance The habit should be broken by appropriate treatment, general and local, so as to assure against any unfortunate results

Acute suppuration is the usual termination of an acute catarrh of the middle ear when of high degree and sudden onset There is the ear-ache, most intense, perhaps, fever and pharyngitis A few hours, or a day or two at most, brings relief by escape of the pent-up products of inflammation through the drum membrane, which yields to the pressure and absorptive action of the matter within the middle ear cavity The inflammation for a time is generally intense and the pain excruciating, but with rupture of the drum membrane comes rapid subsidence of the one and almost immediate cessation of the other Ordinarily the suppurative process comes to an end in a few days or weeks, according to the severity of the attack, the perforation in the drum membrane heals by a cicatricial formation, and hearing becomes usually pretty fair Suppose, however, nature has been allowed to take her course, that no treatment, or insufficient treatment, has been adopted, and what is the result? Careful test will show quite marked loss of hearing, which will not only be permanent, but a condition of the mucous membrane of the middle ear will be left which will tend to increase with age, whereby interference with conduction through the middle ear is more and more interfered with, leading to increased dulness of hearing in after life

---

[1] Medical Society of Arkansas April 22 1885

One attack of acute suppuration predisposes to another, so that chronic suppuration, with its disabling effects, follows, or cicatricial bands form in the middle ear cavity, with anchylosis of the ossicles, pressure on the labyrinth, and other abnormal conditions, resulting in marked diminution of hearing An individual in whom the writer has more than ordinary interest, suffers extreme deafness in one ear from anchylosis and cicatricial formations from repeated attacks of acute suppuration in early childhood, and disagreeable impairment of the other from an unhealthy condition of the mucous membrane implanted at the same time A few words now as to how to avoid such consequences It is presumable, with the literature within the reach of every practitioner of medicine, that the general principles of treatment of these troubles are understood, and I shall therefore put stress only where importance demands it In acute and sub acute aural catarrh, the child's food, clothing and general care should receive special attention Colds are the starting point, and they should be avoided by the observance of those laws of health familiar to every intelligent physician The pharyngeal and naso pharyngeal regions call for suitable remedies The best immediate treatment for the ear is a douche of warm water run in a continual stream into the outer ear, or syringed, or poured, in want of the ear douche Cocaine, atropia or morphia may be tried in warm solution, but personal experience leads me to rely more on the free use of pure warm water, both as an anodyne and as a curative agent, than any other topical remedy After the douche or syringe is used a pledget of cotton should be worn in the outer meatus, both to protect from cold and to retain the heat and moisture There is usually an accumulation of mucus in the middle ear cavity, together with obstruction of the Eustachian tube by œdema and collections of mucus In order to open the tube and restore the balance of pressure between the middle ear space and the outer atmosphere—a rarefaction of the air in the middle ear having resulted from absorption—it is necessary to resort to inflation through the Eustachian tube This is best done by Politzer's or Gruber's method, the latter being the method in infants who unconsciously, in crying, emit the sounds necessary to closing the space between the middle and upper pharynx This should be done daily until the acuteness of the attack has subsided, and then less often until there is complete restoration of equilibrium between the throat and middle ear cavity, and proper patency of the Eustachian tube insured. Failure in this may be the cause of permanent injury to hearing by long continued rarefaction in the middle ear and pressure on the drum-membrane and chain of bones from without

In dealing with acute suppuration, treatment should begin at the commencement of the attack, and suppuration averted, if possible In the stage of acute catarrh, a hot foot-bath, diaphoretics, uniform temperature, and warm douching of the outer ear will afford wonderful relief, and often terminate the attack short of suppuration But if suppuration is imminent, and the drum-membrane bulging, paracentesis should be resorted to, rather than allow spontaneous rupture with a ragged opening and much cicatricial contraction in healing A paracentesis at this stage generally gives exit to serum and mucus tinged with blood, from the incision in the drum-membrane, followed by almost immediate relief from pain After the paracentesis a Politzer should be given to blow out the fluids accumulated in the middle ear All syringing after this should be done with aseptic fluids By careful attention to details, suppuration may not follow, even when this state of affairs has been reached, and the paracentesis is an important factor, when timely done, in averting such result If suppuration does not follow, the further treatment should be the same as already suggested for acute catarrh If suppuration follows, it should be treated by cleanliness antiseptics and astringents, until it has ceased, and the perforation in the drum membrane healed At this stage the patient is commonly discharged and all treatment suspended, and it is just here that seeds are sown for future trouble The mucous membrane of the middle ear is still in a swollen and infiltrated condition, the drum membrane has a contracting cicatrix forming, altering its curvature, and by bands of cicatricial formations within, being drawn inwards and causing pressure on the labyrinth through the foot of the stapes, the Eustachian tube remains for some time impervious to natural methods of opening it, and rarefaction of the air in the middle ear thereby ensues, thus augmenting the labyrinthine pressure and disturbing proper circulation, in that the arterial walls in the mucous membrane do not meet with proper resistance Slowly these abnormal processes recede towards a healthy condition, but quite commonly stop short of it, and in the course of time, defective hearing, with constant tinnitus aurium but too plainly point the result of insufficient treatment

When the suppurative process is at an end, and the perforation in the drum membrane has been filled is from 4,000 to 8,000 feet above the sea The winters are mild and dry and the rainfall slight, being from ten to fifteen inches a year The little rain that falls comes mostly in summer showers On the whole, it would seem well proved that New Mexico is the proper residence for consumptive patients Colorado has also stood deservedly high in these respects, but the figures in the census have been made to appear less favorable than those of ten years ago, in consequence of the really large number of consumptives who have been taken thither in the advanced stages of the disease

The question is often asked, "Do cancer and consumption on the whole increase in the community?" The following figures convey the substance of what is known on the subject They are obtained by averaging the ratio of all the States and Territories for the only three censuses which have recorded any mortality statistics

Table showing the Proportion of Deaths from Cancer and Consumption to Deaths from all Causes in the whole United States in 1860, 1870 and 1880

	1860	1870	1880

CONSEQUENCES OF ACUTE AURAL TROUBLES IN CHILDREN WHEN NOT PROPERLY ATTENDED TO[1]

BY T E MURRELL, M D ,

OF LITTLE ROCK ARK

In examining many persons one is struck with the varying degrees of hearing power in different individuals, and in different ears of the same individual So much so is this the case that it has been extremely puzzling to fix a standard of hearing power, even though the character of the test be agreed on, which is in itself a difficult problem But, to meet all peculiarities, we will presume the various methods in common use are tried on each person under test, and a comparative estimate deducted therefrom In this manner there is found a very great difference even in persons of presumably normal condition—persons who have no catarrhal affection and no history of ear disease If one selects for his examination persons beyond middle life he will find few whose hearing reaches the highest standard Causes arising in the course of life from climate, mode of living, habits and vocation, lead to defective hearing, not to mention acute affections incident to exposure, general diseases, and accident

Omitting all causes arising after childhood, we will only consider acute affections in children as causative of dulness of hearing in after life

Many persons with impaired hearing who can give no history of their trouble, have likely suffered from some middle ear affection in infancy or early childhood, a period of life in which records of disease are readily lost In proof of which statement, a careful inspection of the drum membranes of such persons will often reveal evidences of former trouble In childhood nearly all diseases are acute primarily, to which affections of special organs are not exceptions The two diseases of the ear most frequent in infancy and early childhood are acute catarrh and acute suppuration of the middle ear Not only the mother, but also the physician, is quite liable to overlook an ear ache in an infant The cause of its plaint is unsuspected in the search for the more common pains and distresses of this time of life By reason of, or in spite of, expectant remedies, the sufferer assumes its usual playfulness in a few hours, or days, and all goes well until another such attack comes on at some indefinite future period These attacks may repeatedly recur—being often of a sub-acute type—before the cause is ascertained During one of the attacks a careful inspection of the fauces would reveal a redness with, perhaps, œdema, and of the drum membrane, an injection along the handle of the malleus or a uniform redness When the attack has passed away no vestiges of it may remain, either in hearing power or appearance of the parts involved But should they be often repeated the mucous membrane of the pharynx and middle ear gradually assume abnormal conditions, the lymphatics become engorged, the tissues pervaded with formative elements, the arterioles enlarged and capillaries congested, and the functions of the parts altogether disturbed If the perturbating causes are now removed, there is a tendency to restoration to a healthy condition, but often a vulnerability remains, whereby the slightest exciting cause, as a cold in the head, is sufficient to renew the morbid processes It is fortunate that all acute and sub acute catarrhs of the middle ear in infancy and early childhood do not, from neglect, terminate in injury of a permanent character Enough do, however, to warrant particular stress on the importance of proper attention being given them, notwithstanding the popular idea of their unimportance The habit should be broken by appropriate treatment, general and local, so as to assure against any unfortunate results

Acute suppuration is the usual termination of an acute catarrh of the middle ear when of high degree and sudden onset. There is the ear-ache, most intense, perhaps, fever and pharyngitis. A few hours, or a day or two at most, brings relief by escape of the pent-up products of inflammation through the drum membrane, which yields to the pressure and absorptive action of the matter within the middle ear cavity. The inflammation for a time is generally intense and the pain excruciating, but with rupture of the drum membrane comes rapid subsidence of the one and almost immediate cessation of the other. Ordinarily the suppurative process comes to an end in a few days or weeks, according to the severity of the attack, the perforation in the drum membrane heals by a cicatricial formation, and hearing becomes usually pretty fair. Suppose, however, nature has been allowed to take her course, that no treatment, or insufficient treatment, has been adopted, and what is the result? Careful test will show quite marked loss of hearing, which will not only be permanent, but a condition of the mucous membrane of the middle ear will be left which will tend to increase with age, whereby interference with conduction through the middle ear is more and more interfered with, leading to increased dulness of hearing in after life.

---

[1] Read before the State Medical Society of Arkansas, April 22 1885

One attack of acute suppuration predisposes to another, so that chronic suppuration, with its disabling effects, follows, or cicatricial bands form in the middle ear cavity, with anchylosis of the ossicles, pressure on the labyrinth, and other abnormal conditions, resulting in marked diminution of hearing. An individual in whom the writer has more than ordinary interest, suffers extreme deafness in one ear from anchylosis and cicatricial formations from repeated attacks of acute suppuration in early childhood, and disagreeable impairment of the other from an unhealthy condition of the mucous membrane implanted at the same time. A few words now as to how to avoid such consequences. It is presumable, with the literature within the reach of every practitioner of medicine, that the general principles of treatment of these troubles are understood, and I shall therefore put stress only where importance demands it. In acute and sub-acute aural catarrh, the child's food, clothing and general care should receive special attention. Colds are the starting point, and they should be avoided by the observance of those laws of health familiar to every intelligent physician. The pharyngeal and naso-pharyngeal regions call for suitable remedies. The best immediate treatment for the ear is a douche of warm water run in a continual stream into the outer ear, or syringed, or poured, in want of the ear douche. Cocaine, atropia or morphia may be tried in warm solution, but personal experience leads me to rely more on the free use of pure warm water, both as an anodyne and as a curative agent, than any other topical remedy. After the douche or syringe is used a pledget of cotton should be worn in the outer meatus, both to protect from cold and to retain the heat and moisture. There is usually an accumulation of mucus in the middle ear cavity, together with obstruction of the Eustachian tube by œdema and collections of mucus. In order to open the tube and restore the balance of pressure between the middle ear space and the outer atmosphere—a rarefaction of the air in the middle ear having resulted from absorption—it is necessary to resort to inflation through the Eustachian tube. This is best done by Politzer's or Gruber's method, the latter being the method in infants who unconsciously, in crying, emit the sounds necessary to closing the space between the middle and upper pharynx. This should be done daily until the acuteness of the attack has subsided, and then less often until there is complete restoration of equilibrium between the throat and middle ear cavity, and proper patency of the Eustachian tube insured. Failure in this may be the cause of permanent injury to hearing by long continued rarefaction in the middle ear and pressure on the drum membrane and chain of bones from without.

In dealing with acute suppuration, treatment should begin at the commencement of the attack, and suppuration averted, if possible. In the stage of acute catarrh, a hot foot-bath, diaphoretics, uniform temperature, and warm douching of the outer ear will afford wonderful relief, and often terminate the attack short of suppuration. But if suppuration is imminent, and the drum-membrane bulging, paracentesis should be resorted to, rather than allow spontaneous rupture with a ragged opening and much cicatricial contraction in healing. A paracentesis at this stage generally gives exit to serum and mucus tinged with blood, from the incision in the drum membrane, followed by almost immediate relief from pain. After the paracentesis a Politzer should be given to blow out the fluids accumulated in the middle ear. All syringing after this should be done with aseptic fluids. By careful attention to details, suppuration may not follow, even when this state of affairs has been reached, and the paracentesis is an important factor, when timely done, in averting such result. If suppuration does not follow, the further treatment should be the same as already suggested for acute catarrh. If suppuration follows, it should be treated by cleanliness antiseptics and astringents, until it has ceased, and the perforation in the drum membrane healed. At this stage the patient is commonly discharged and all treatment suspended, and it is just here that seeds are sown for future trouble. The mucous membrane of the middle ear is still in a swollen and infiltrated condition, the drum membrane has a contracting cicatrix forming, altering its curvature, and by bands of cicatricial formations within, being drawn inwards and causing pressure on the labyrinth through the foot of the stapes, the Eustachian tube remains for some time impervious to natural methods of opening it, and rarefaction of the air in the middle ear thereby ensues, thus augmenting the labyrinthine pressure and disturbing proper circulation, in that the arterial walls in the mucous membrane do not meet with proper resistance. Slowly these abnormal processes recede towards a healthy condition, but quite commonly stop short of it, and in the course of time, defective hearing, with constant tinnitus aurium but too plainly point the result of insufficient treatment.

When the suppurative process is at an end, and the perforation in the drum membrane has been filled by cicatricial tissue, it is imperative, in so far as the integrity of hearing for the future is concerned, that methodical treatment should be given The drum-membrane should be exercised, together with the chain of bones, to prevent anchylosis and loss of motion, the Eustachian tube should be daily opened so as to restore a proper balance between the air in the middle ear and the outer atmosphere in order to avoid rarefaction and congestion of the mucous membrane, and the naso pharyngeal region should be toned up by appropriate remedies

To effect the first and second, the best means at our command is the air-bag, and the preferable method of using it is according to Politzer A Politzer should be given daily until hearing is restored to normal or nearly normal (a certain amount of impaired hearing nearly always remains after a severe supperative otitis media), which should be determined by carefully repeated tests, if the child is old enough for such tests, or so long as will insure all the restoration possible in case it is not By the observance of these rules no very great impairment of hearing ought ever to follow an ordinary case of suppurative otitis media, either immediately or remotely The importance of this finishing treatment in these cases should be more generally recognized, and is as applicable in older persons as in children One of the consequences of acute suppuration of the middle ear in children, viz , chronic suppuration, is only mentioned to remind of the importance of proper attention to the acute affection The exanthemata in children excite the most violent and destructive suppurative processes in the middle ear, which show a special tendency to become chronic, but by appropriate and persevering treatment resolution with very fair hearing is almost invariable

THE TREATMENT OF MALARIAL AILMENTS FROM THE STANDPOINT OF THE GERM THEORY[1]

J S SHIBLEY, M D,

OF PARIS ARK

It would doubtless be premature, at this time, to accept the germ theory of malaria as a demonstration, but it may be received as a "good working hypothesis" and a trusty guide to the treatment, which to my mind it greatly simplifies

The treatment of malarial diseases, is so old a subject, that it is after some hesitation that I have concluded to obtrude it on your attention Yet, when we remember that hundreds of deaths occur, every year, in our State, from this cause, every one of which ought to be prevented, we may well give to it our earnest attention Not until it is so well and so generally understood, that every case treated shall be cured, will it be out of order to discuss it

For the present, let us assume that the malarial poison consists of living organisms which, having gained access to the circulation are carried with the blood current to every organ and tissue That these organisms have the power under favorable conditions, of multiplying in the system, reproducing generation after generation indefinitely, and deriving the material for their production and growth from the living tissues, especially the blood and nerve tissue This process of reproduction and growth of the morbific agent, excites in some way unknown to us, a rise in the temperature of the patient, with all its accompanying phenomena—a fever, which is natures reaction against the morbid process, and by which it is at length interrupted more or less completely, producing an intermission or a remission But the poison is not all destroyed, some of it remains in the system, and at the appointed time will again give rise to the same sequence of events Such is the course in ordinary intermittents and remittents But should the system from some cause, fail to react by fever against the germs, they multiply unchecked to the speedy destruction of the patient, as we see in cases of malarial collapse, mis-called congestive chills

From this view of the nature of malarial poisoning, we can readily see why the eliminative treatment, whether by vomiting, purging or sweating, is so little satisfactory, since there is no evidence that the poison is eliminated by either of these methods The derangements of the digestive and biliary organs are the effects of the morbid process, and not its cause, as formerly supposed They are very closely allied to, if indeed they be not a part of, the nervous phenomena, and they will vanish rapidly on the removal of the cause

The curative treatment is antidotal, and its proper application consists in the selection of such germicides as will kill the bacteria, and in using them in such manner as to be both effective and harmless Fortunately, we have in the alkaloids of the cinchona bark the efficient germicide, but we cannot say that it is always harmless Indeed its use under the varying conditions of malarial ailments, required constant care and no little caution to cure the disease without injury to the patient

To summarize the treatment of malarial fever 1st, It should be instituted with the least possible loss of time The longer the germs are permitted to multiply and grow, the greater will be the damage inflicted on the system Delay is dangerous, for even mild seeming cases may become pernicious 2d, It is usually better to allay the nervous symptoms before resorting to the antidote A full dose of opium in some form, with one of the bromides or with hydrobromic acid, is the best preparatory treatment Besides relieving pain, vomiting, etc , it renders the system more tolerant of the action of the germicide 3d, The cinchona salt should be given as soon as the opiate takes effect, and in sufficient, but not excessive doses Eight or ten grains of quinine for a first dose, followed by five grains every two or three hours till the fever yields, the influence of the opiate and bromide being sufficiently maintained to prevent distress of any kind, will usually effect a cure speedily, safely and pleasantly Excessive doses of quinine, such as thirty or forty grains, are unnecessary, unpleasant and unsafe 4th, After the cessation of the fever, the system should be fortified against the growth of any germs that may remain, by the continued administration of germicides and hæmatinics The best are cinchona arsenic and iron, and their use should be persisted in till the cure is complete

---

In pernicious fever, the same principles guide us in the treatment The leading indication is to destroy the morbific germs as quickly as can be done with safely to the patient

In the comatose variety, the coma is not the index of congestion of the brain, but of the injury done to the nerve centers by the malarial parasites It will yield readily to the treatment that removes its cause, *i e* to cinchonization As the patient gets under the influence of quinine he will wake up as from a sleep

In the convulsive variety, the convulsions are but another manifestation of the action of the poison on the nervous system But in this case it will not be safe to resort to the antidote till the irritation of the nervous system has been allayed Quinine and all its congeners are nervous irritants, and may add to the danger We must first place the shattered brain and nerves in splints, so as to speak For this purpose, morphia, given subcutaneously, is prompt, efficient, and safe Then bring the system quickly and decidedly, though not excessively, under the influence of quinine, and you cure your patient

The algid variety is much the most serious and dangerous form Here the system does not react against the poison The great danger lies in the excessive depression of the circulation This would seem to be secondary to irritation of the nerve centres by the poison, and brought about by reflex action, being analogous to the condition of shock in surgical injuries The problem is to maintain the circulation till the career of the destroying bacteria can be arrested To fulfil this indication, morphia and atropia, by cutting off the reflex irritation from the heart and digitalis, as a cardiac stimulant, are exceedingly valuable One fourth grain morphia with one sixtieth grain atropia may be given by subcutaneous injection and repeated every half hour until improvement in the pulse is manifest, or until the narcotic effects of the morphia begin to appear Ten drops of the fluid extract, or half a dram of the tincture of digitalis may be given in the same way and at the same interval, till the stimulant effect of digitalis is obtained Of course remedies so powerful, are to be used with prudence, but it is necessary to use them so as to be promptly effective, ere the opportunity for treatment be forever past At the same time we should give by the mouth moderate doses of quinine in solution, say five grains every two hours I do not now make use of tablespoonful doses as I once did They are too depressing and I fear may add to the peril of the patient

This treatment by morphia, atropia and digitalis has been followed by Dr T D Nichols, of Paris, and myself, for several years, with a very gratifying degree of success, having saved several cases such as uniformly died under the treatment formerly pursued by us, which consisted in the use of friction, heat, and rubefacients externally, and diffusible stimulants and heroic doses of quinine, internally Latterly we have discarded all disquieting measures, as tending still further to depress the vital force, which we endeavor to husband by rest and comfort, inflicting no further pain than what is caused by the hypodermic injections

In severe cases of malarial collapse medication of whatever sort by the mouth alone, is apt to prove inefficient, for if the medicine be not rejected the stomach has little power to dissolve or absorb it The essential point is to bring about reaction, to re-establish the functions of the vascular system, so as to allow the great antidote to be absorbed and brought into contact with the poison in the circulation

In pernicious fever in all its forms we must divest our minds of the idea of congestion, as the essential pathological condition Whatever degree of congestion may be present is only symptomatic of the action of the malarial poison on, or through, the vaso-motor system of nerves, and it will disappear on the removal of its cause

INJECTIONS OF ETHER IN SCIATICA[1]

BY Z ORTO, M D,

OF PINE BLUFF, ARK

I desire to call attention briefly, to a case of sciatica, successfully treated by hypodermic injections of sulphuric ether

On Oct 29, 1884, I was called to see Mrs C, whom I found in bed, suffering greatly with pain in her right leg and hip—unattended by redness or swelling Mrs C is 39 years old, of a nervous temperament, has a good family history, and has always had good health until the birth of her last child, which occurred on Feb 14, 1883 The patient states that three days after the birth of this child fever came on, and continued for about six weeks, during which time she was unconscious, and that when the fever ceased and conciousness returned, she was unable to move her right leg without excruciating pain There were spasmodic contractions of the limb, which caused great suffering She states she remained in about the same condition, except that there was a gradual wearing away of the pain, for six months, at the end of which time, she was able, by the aid of crutches, to move around the house, but at no time was she free from pain—and two weeks prior to my first visit she was again seized with the intolerable pain in her right hip and leg that had previously caused so much trouble She at once went to bed, and had been compelled to keep under the influence of opium

On examination, I found tenderness all along the course of the sciatic nerve, and, as before stated, without redness or swelling of the limb All movements of the limb had to be performed by the aid of the patient's hand applied to the thigh, and with the left foot under the right I at once diagnosticated sciatica, and having read of some cases successfully treated by hypodermic injections of sulphuric ether, by Dr C G Comegys, of Cincinnati, published in the *Cincinnati Lancet and Clinic*, for July, 1878, I determined to give this remedy and method a trial

---

[1] Read before the State Medical Society of Arkansas April 23d, 1885

On the morning of November 30, my patient received the first injection of twenty drops, the syringe being inserted behind the trochanter major, the point recommended by Dr Comegys The injections were given in the ordinary superficial way Seven injections were used in all, at intervals of twelve hours, using in the last six thirty drops each The injections were followed by violent pain of a burning character, which, however, soon passed off The patient declared she could taste the ether distinctly by the time the syringe was withdrawn The acute neuralgic pain was relieved by the first injection, and never returned as severely as before Improvement was noted from the beginning, the patient sleeping soundly without any other anodyne The progress of the case was favorable, though rather slower than those of Dr Comegys, though I think this may be accounted for by the former condition of the patient In less than ten days the patient was able to be out of bed, and has since been attending to her domestic affairs, enjoying perfect health, save a little stiffness in her right leg

So far as I am aware, Dr Comegys was the first to call the attention of the profession to the value of this remedy in sciatica From my experience with ether, in this one case, I am prepared to agree with him when he says "in this I believe we have a safe and efficient remedy for this troublesome and painful disease" He believes it to be equally efficacious in circumflex neuralgia as well as *tic douloureux* Heretofore ether used hypodermically has not been satisfactory as an anodyne As a stimulant to the heart's action, it has been used quite extensively by some practitioners

Arnozan, in a recent publication, states that ether when used hypodermically produces an acute neuritis Its action in sciatica is certainly open to investigation, and cannot be harmonized with the above theories, if our present view of the pathology of sciatica be correct Local irritation rarely ever results from its use

Pine Bluff, Ark , April, 1885

MEDICAL PROGRESS

MATERIA MEDICA AND THERAPEUTICS

Therapeutics of Jaborandi —M Petithan, in a paper upon the therapeutic uses of jaborandi, claims its efficacy in the treatment of the following diseases

2 In all catarrhal and rheumatic affections, sub acute or chronic, whatever may be their localization

2 In all dropsical conditions, without alteration in the kidney, when anæmia is not too marked

3 In certain cases of pernicious intermittent fever in which reaction is hastened without affecting the action of quinine

4 In malignant febrile exanthemata, especially in scarlatina

5 In diseases of the skin, characterized by dryness, psoriasis, etc

6 In chronic syphilitic disease during the employment of mercury and the iodides

7 In mercurial intoxication

8 Probably in diphtheria

The remedy according to M Petithan, should be used as follows

1 It should be administered when the patient is fasting

2 The dose should vary according to the case, 60 grains being an average quantity

3 The temperature of the infusion should vary according to the degree in which the sudorific effect is desired

4 A local temperature of at least 66° F should be constantly maintained

5 The patient should not be permitted to leave his bed on any pretext unless well covered, in order to avoid variation of temperature and syncope, which may result therefrom

6 Warm drinks should be administered if the patient is thirsty, a condition very rare owing to the salivation produced by the drug

7 The employment of a good quality of the drug, that of Coutinho being the best

8 To have at hand stimulants such as ammonia, etc , to sustain the patient

9 If necessary to administer an antidote, M Petithan suggests the employment of belladonna —*Bulletin General de Therapeutique*, July 15, 1885 —*Medical News*, September 26, 1885

MEDICINE

Poisoning by Cocaine —Dr W B Merriman reports the following case C J , aged 28 years, formed the morphine habit by taking it for sick headache On or about May 1, he went to Cleveland and was advised by a physician to take cocaine, and it sickened him He commenced by using one drachm of the four per cent solution per day, and gradually increased the dose till he was taking from five to seven drachms per day hypodermically I was called to see him on September 17, and found him with low grade fever, pulse 100 and very weak, mind wandering, very nervous, had had no sleep for three days, in fact, going through all the grades of delirium tremens Bromides and stimulants quiet him while he is under their influence —*Cin Lancet and Clinic*, Sept 26, 1885

Benzol in Epithelioma of the Eyelid —At the meeting of the Brooklyn Pathological Society, on March 12, 1885, Dr Arthur Mathewson reported the following history of a case An Irish laborer, 50 years old, was first seen October 31, 1883, when he had a growth on the right lower lid, projecting two-thirds of an inch, with an ulcerated surface It had first been noticed, as a warty excrescence, a year or two before, and had lately begun to grow rapidly Microscopical examination, by Dr W H Bates, showed it to be clearly an epithelioma At first the treatment consisted in dusting the granulating surface with calomel, afterwards (at the suggestion of Dr Bates, who had records of two cases of epithelioma treated successfully, in his own practice, with the agent) in applications of benzol After about three months' use of these remedies, applied three or four times a week, the growth had completely disappeared, leaving a smooth, depressed cicatrix On the 1st of March 1885, the man came back, with the history of a small ulcerating spot having appeared some six months before at the outer edge of the cicatrix This was extending rapidly, but quickly began to contract under renewed applications of the same remedies, and was much reduced in size when the patient was presented at the April meeting of the New York Ophthalmological Society On the 1st of May, when the patient left town, it was scarcely noticeable On the 8th of July the man appeared again, with a considerable increase in the size of the ulcerating surface, but it had again yielded promptly to the applications The benzol was brushed over the ulceration and the adjacent surface after they had been carefully wiped, and calomel was then dusted on The applications were made from two to four times a week —*N Y Med Journ*, Sept 26, 1885

TANGHIN IN NERVOUS DISEASES —This ordeal poison of Madagascar, derived from the apocynaceous tree variously named by botanists *Cerbera venenifera*, *C manghas*, *C tanghin*, *Tanghinia venenifera*, and *T veneniflua*, has been made the subject of experiment by M C E QUINQUAUD Its action on the central nervous system is specially characterized by an exaltation of the bulbo spinal reflex activity After a certain number of experiments on animals, M Quinquaud administered an extract to man, in doses ranging between three quarters of a grain and a grain and a half, in various diseases, notably toxic paralyses, tremor, intestinal atony, and incontinence of urine Satisfactory effects were obtained, but only on condition that the use of the drug was ceased as soon as the patients experienced headache, nausea, vomiting, and a certain amount of debility —*Gazette Hebdomadaire*

SURGERY

A MODIFICATION OF THE PROCEDURE OF WIRING BONES —DR WM H FLUHRER, of New York, after describing his instruments for this operation, gives the following details

The bones to be wired are sufficiently bared, but need not be completely denuded The withdrawal of the soft parts for drilling through the smallest possible incision is effected by means of the grooved retractor, which not only retracts but at the same time depresses the obstructing tissues The drill is passed along the channel of the retractor directly to the bone, cutting its way through any overlying soft tissues by an incomplete rotary motion When the bone is reached the drill should never be withdrawn in any degree for fear of fouling, but should be urged onward by a rotary motion with continuous and light pressure The drill being made in one piece, and larger at its head than in the shank its progress, like that of a probe, can be nicely felt as it passes through the bone, which would not be the case were the mechanism for drilling a complicated one or were the drill driven at high speed In drilling transversely through a bone, as in the case of the upper end of the tibia, the passage of the head of the drill through the proximal portion of compact bone, through the cancellous structure, the striking of the distal portion of compact bone and its passage through it can all be clearly discriminated The emergence of the point of the drill having been detected by the finger watching at the presumed place of exit, or being known by the change in resistance, the next step is to pass a loop of silk through the bone to serve as a conductor for the wire suture The silk should be of a thickness barely large enough to fill the notch in the drill When the end of the drill is far below the surface, the fork is needed to deposit the thread in place When the soft parts crowd upon the buried end of the drill, they should be pressed back by using the retractor, then the end of the drill is received into the groove of the retractor, and is easily accessible to the fork carrying the loop of thread When the silk has been lodged in the notch, it is held there by gentle counter-traction, while the drill is cautiously withdrawn without rotation, leaving the thread in its place When the end of the drill is far below the surface, the counter-traction may be exerted through the medium of the fork By a dexterous movement the loop may be shifted from the secondary forks into the crotch of the primary fork around which it plays as a pulley as it is drawn through the bone It is essential that the closed ends of the loops should lie between the bones to be wired If, therefore, a loop needs reversing, a second thread is passed through the existing loop, by means of which the new loop is pulled through the bone into position The free ends of the thread are then passed through the loop and drawn tightly across the face of the bone, thus lining off the broken or sawn surface, and indicating clearly where the drill should be passed through the opposing bone

The conducting loops, or guides, for the wire sutures having been lodged in place, the next step is the drawing of the wires into position The bent end of the wire suture is hooked in the end of a loop of thread which has been freed, and under a little counter traction is fed to the opening while the operator pulls upon the conducting loop and draws one-half the wire through the bone The end of the remaining half of the wire is then caught into a corresponding loop through the opposing bone, and is drawn into position The bones having been brought into close apposition, each wire is embedded before being twisted While the ends are held in their future position the scalpel is drawn alongside, cutting the subjacent soft parts and letting the wires sink down to the bone The tightly drawn ends are then twisted and cut short to the twist, which is turned down The slits in the soft parts are closed over the wire, which is to remain permanently, by a fine catgut suture

By proceeding in the manner I have detailed, the wiring together of bones is a precise, easy, and expeditious operation It can be done without extruding the ends of the bones through the soft parts, it being only necessary to cast the guiding loop of thread over the end of the drill, no matter how deeply the latter may be situated It is easy to carry the wire transversely through the whole extent of bone, thus securing an effective hold upon it. A suture only dipping into the cancellous structure, as is the case in the usual mode of wiring after an exsection of the knee-joint, may be regarded as a slack wire. It generally cuts partly through the soft bone tissue before the surgeon can apply retentive apparatus to the limb. On the contrary, when the sutures have been passed completely through the bones in the manner just described, they alone hold the bones firmly in apposition, and the grating formed by the wires prevents the intrusion of the soft parts. In an exsection of the knee joint, in addition to four wires passed antero-posteriorly, I also bind the bones together by a wire passed transversely, which acts as a substitute for the lateral ligaments. In simple fractures of the patella, exsections of the knee joint, and compound fractures, I have passed the drill more than thirty times, besides being present when others have operated in the same manner, and I have never seen a failure or miscarriage in the execution of any step of the procedure.—*Medical Record*, September 26, 1885.

On Erasion (so-called Arthrectomy) of the Knee.—Mr. G. A. Wright reports to the *Medical Chronicle* July, 1885, his experience with this operation in sixteen cases. The operation consists in opening the joint freely by a semilunar incision, just as in the ordinary mode of excising the knee, the skin is reflected and the capsule removed on each side of the patella and patellar ligament, or, if preferred, the patella may be sawn across and the fragments turned upwards and downwards. If the former plan is employed, free incisions parallel to the long axis of the limb are made on each side of the patella, extending a little above its upper border as well as downwards nearly to the insertion of the ligamentum patellæ into the tubercle of the tibia, the object of this is to allow the patella to be freely displaced laterally, and turned round so as to expose its articular aspect during the process of erasion.

The rest of the operation consists in carefully cutting away with forceps and scalpel or scissors every particle of pulpy granulation tissue, all the infiltrated capsule and the semilunar cartilages, and scraping quite clean all the articular cartilage, picking out granulation tissue from any pits in the cartilage, and, if necessary, gouging away any small spots of diseased bone. The process must be most thorough, and extreme flexion of the limb is required to completely expose and clean the posterior part of the joint, the crucial ligaments are scraped, but carefully preserved, the lateral ligaments usually divided.

The upper synovial sac must be thoroughly cleaned. The most difficult part of the operation is getting away the posterior part of the semilunar cartilages, and the synovial membrane at the back of the joint.

The process is a tedious one, often taking one and a half or two hours, including the subsequent putting up in a splint. As soon as all bleeding has been stopped, the limb is fixed on an excision splint and dressed in the usual method, antiseptically. Wood wool is the dressing Mr. Wright prefers, from its perfect absorbent properties, and the firm, even support it gives, drainage should be at the back of the joint on each side, as after excision, the tubes being carried through openings made behind the joint. He prefers to Esmarch the limb before beginning the operation.

His reports include cases of pulpy disease with no suppuration, cases with varying amounts of bone disease, some with extensive abscess, some with small amounts of abscess, and, finally, cases where there was general tuberculosis. In those that have done well the common factors appear to be (1) Absence or very small amount of suppuration. (2) Superficial or at least not wide spread bone disease. (3) Absence of general tuberculosis. In short, fairly early disease in a not hopelessly tuberculous child. Although in one case a freely movable joint resulted, he does not advise the attempt to obtain motility by early passive movement, except in a few instances where the wound has healed at once, and there is no obstacle in the way, such as dense and lowly vitalized cicatricial tissue. Erasion, if it fails, leaves the limb in little, if at all, worse condition for excision afterwards. In those cases where amputation became necessary, either the local or constitutional condition forbade hope of successful excision. Where it succeeds, erasion leaves as sound a limb as excision, without shortening. The limb is very liable to become flexed after healing of the wound. He thinks, then, that in suitable cases erasion is, in disease of the knee, better surgery than excision, but its application is strictly limited.

Treatment of Incarcerated Hernia by Ether Irrigation.—In the *Russkaia Meditz.*, No. 3, 1885, p. 62, Dr. V. Bartosz, of Romny, Poltava Government, writes that during the last two years he used ether with brilliant success in all his cases of strangulated hernia, seventeen in number. Irrigation was performed after Finkelstein's method, that is, a tablespoonful of ether was poured over the tumor every half hour. The hernia disappeared spontaneously, or under slight pressure in the worst cases, within four or five hours. The duration of strangulation varied between a few hours and four days. The author describes, also, a case of internal intestinal obstruction in a woman, aged 60, with nine days' constipation, incessant fæcal vomiting, tympanites, thready pulse, etc., in which, after all the usual means had failed, ether irrigation all over the abdomen brought about profuse stools in an hour and a half, the patient completely recovering.—*London Med. Rec.*, 1885; *Practitioner*, July, 1885.

Veterinary Surgery.—Mr. Snarry, a veterinary surgeon, has accomplished a novel feat in the way of surgery. A cow on the Westow Grange Farm, near York, broke its leg, and there being no chance of reducing the fracture, the limb was amputated, and Mr. Snarry tried the experiment of affixing a wooden leg. This has been found to answer admirably, and the cow may be seen grazing, with a calf by its side.—*The London Medical Record*, September 15, 1885.

HARD TO PLEASE

It is an old saying that none are so blind as those who do not wish to see And it is equally true that none are so difficult to please as those who have no desire to be pleased This is strikingly exemplified by the course of those few leading medical journals whose editors have undertaken to place all the obstacles possible in the way of successfully organizing the Ninth International Congress in this country Although it was through the direct influence of a report made by a special Committee of which Dr J S Billings and Dr I Minis Hays, editor of the *Medical News*, were leading members, that the American Medical Association was induced to appoint a Committee and authorize it to invite the International Medical Congress at Copenhagen, in behalf of the profession of the United States, to hold the next Congress in this country, yet so soon as the Association at its next meeting, held in New Orleans, insisted on having the terms of the invitation carried out by so altering and enlarging its Committee as to make it properly represent the profession of the United States, instead of a certain class in three or four cities, these same men took the lead in claiming that the Association had no right to meddle with the Congress in any way, or even with the Committee of its own creation

When, notwithstanding their protest, the enlarged Committee, composed of able representatives from the several States, held its first meeting, and had only partially accomplished its work of preliminary organization, and before any authorized publication of the action taken, these same men, with a few friends, backed by the *Medical News*, *Medical Record*, and the *New York Medical Journal*, commenced a sudden but well concerted scheme of revolt or withdrawal from all participation in the Congress "as then proposed to be organized" This unprecedented and most unjustifiable course was ostensibly based on the pretense that the Committee had restricted the American Membership to delegates from the American Medical Association and the State Medical Societies in affiliation therewith, leaving out the national organizations of specialists, and thereby excluding large and influential portions of the profession from participation in the Congress But when, after time for further consideration, the Committee of Arrangements held another meeting, and unanimously adopted Rules by which membership of the Congress was opened to all "members of the regular medical profession" in this and other countries alike, as fully as has been claimed for preceding Congresses either by Sir James Paget or Dr Noyes, and from which all allusions to ethical codes, creeds, or distinctions of any kind were carefully excluded, the same parties and organs declare that the Committee has offered no compromises and has given no heed to the sentiments of distinguished men in Europe

When the Committee of Arrangements, after adopting Rules with which the opposition could find no possible fault, and filling a sufficient number of appointments to constitute, under the Rules, the working part of the Preliminary Organization of the Congress, all further management of the affairs of the Congress was transferred to that organization, thereby making it as independent as any preceding Congress, the *Medical News* manifests its disgust by expressing the hope that the nation may be spared the disgrace of having the Congress held in this country, and singularly enough the *Medical Record*, not quite willing to have the Congress removed from this country, turns as its last hope to some *action* of *the American Medical Association* at its coming meeting in St Louis for relief

Finally, when the members of the recently created Executive Committee of the Congress itself hold their first meeting, and, in accepting the responsible duties assigned to them under the Rules of Organization, they declare that in doing so, it is with the full understanding that their action is to be restrained only by the Rules already adopted by the Committee of Arrangements, all three of the leading organs of opposition substantially charge the Executive Committee with rebellion against the authority of the Association, and with one accord, rehash and republish the full list of those who had *declined* months previously to participate, not in the present organization, but in the organization as suggested at the first meeting of the Committee, in June last. Verily the managers of those journals must be hard pushed for material when they, by concert, resort to such subterfuges to keep up an appearance of opposition. They well know that the republication of this, now obsolete, list of declinations can have no effect in this country, but they evidently hope to keep up the impression in foreign countries of opposition to the present organization, and thereby discourage attendance from those countries. It is evident, from all the foregoing, that nothing has been done in the past, or will be done in the future, pleasing to those parties, except the action of the American Medical Association in Washington in 1884, when, yielding to the arguments of their own report, it adopted the resolutions by which they were appointed a Committee with what they supposed to be *plenary power* to appropriate the chief offices of the Congress to themselves, and distribute the rest among their personal friends.

LACTIC ACID IN THE TREATMENT OF LARYNGEAL PHTHISIS.

The suffering caused by tuberculosis of the larynx is so great, and the treatment of this affection is so unsatisfactory, that any remedy, which promises better results than have been attained hitherto, will be hailed with joy by physician and patient alike. We do not wish to assert that such a remedy has been discovered in lactic acid, but it has yielded such gratifying results in the hands of a German physician, that we think it should be brought to the notice of the profession in this country. The physician in question is DR. H. KRAUSE, a "privat docent," who in his capacity as an instructor seems to have ample clinical material at command. He has published his experience with this agent in the *Berliner klinische Wochenschrift*, of July 20, 1885, in an article entitled "Milchsaure gegen Larynx Tuberkulose."

His attention was first directed to lactic acid as a corrosive agent through a contribution to the *Centralblatt für Chirurgie*, No. 12, 1885, from the pen of V. Mosetig-Moorhof, who had employed it with great advantage first in caries fungosa, subsequently in lupus vulgaris, superficial epitheliomata, and in one case of broad, flat papillomatous growth. Mosetig-Moorhof found that the application of concentrated lactic acid caused the diseased tissues to assume the appearance of a blackish broth, while the healthy structures remained uninjured. The epidermis appeared softened and easily removable, yet the cutis was found to be intact. Dr. Krause says the idea of using this acid in tubercular laryngitis was suggested to his mind by the relation supposed to exist between tuberculosis and lupus, and by the unsatisfactoriness of all forms of treatment adopted up to that time. Moorhof had insisted that in order to destroy diseased tissues the acid must be brought into prolonged contact with them, but, realizing in the outset the difficulty of making so thorough an application to the larynx, Krause was not sanguine of success. He selected for his experimentation fourteen persons who had all been treated by means of sedatives, antiseptics and astringents without notable amelioration of the local symptoms. They all presented, on physical examination of the chest, well marked signs of pulmonary tuberculosis, and, upon laryngoscopical inspection, evidences of advanced inflammation. There were all gradations of the laryngeal disease, from greater or less infiltration, or mere ulcerous erosions to deeply penetrating ulcerations, severe perichondritis and infiltration of the highest degree, together with œdema of the mucous membrane. These cases are described at length, but their enumeration here would occupy too much space. The tuberculous nature of the laryngeal affection, Krause thinks, was placed beyond question by the discovery in each of the fourteen cases of the characteristic bacilli.

The author first applied a ten per cent. solution of the acid. The larynx was found to be quite sensitive to it, although this effect was transient. As rapidly then, as was deemed safe, he passed to the use of solutions of twenty five, forty, fifty, sixty, and even eighty per cent. The weaker ones, up to fifty per cent., were attended by the same insignificant symptoms, whereas the stronger ones produced quite violent effects, such as temporary spasm of the glottis and a feeling of burning and dryness, which last persisted anywhere from one to six hours. Krause thinks it necessary to rub the acid thoroughly over the parts and allow it to remain in contact therewith for a short time. As applicator he recommends a not too soft piece of sponge or cotton. In order to reach the more deeply seated ulcerations he employed a syringe by which he applied the medicine in drops. The more violent symptoms soon passed into the sensation of a mild burning and a sourish taste. Other subjective effects were not noted, and even those described were greatly lessened by the application of cocaine previous to the acid. The laryngoscope now revealed a conspicuous paleness and diminution in the thickness of those parts which were previously red and swollen. Occasionally after the application of the stronger mixtures, and constantly after that of the strongest, healthy portions of the mucous membrane had the appearance of being covered with hoarfrost Where this was the case, the more unpleasant effects lasted longer, and the hoarseness was temporarily increased In the next few days the ulcers were observed to be covered by a firmly adherent eschar At the same time were observed a decrease in the swelling and infiltration, and, after separation of the slough, a growth of healthy granulations upon the bottom of the ulcers Excrescences disappeared, while the ulcerated spots cicatrized and contracted These local changes were accompanied by less difficulty in swallowing and an improvement both in the voice and subjective sensations

In one case the ventricular bands, which previously ulcerated and tumefied had touched each other in the middle, looked after two days as if underneath the slough, from their anterior extremity to the point of greatest infiltration behind, they had been hollowed out in places, while they were sharply distinguished by their grayish color from the pinkish hue of healthy parts posterior After the separation of the slough, their deeply depressed surface appeared cicatrized, and close beside the bands crossing it were tiny excavations that looked as if they might have once contained tubercles Altogether, there was a strong similarity to Mosetig-Moorhof's description of lupus after its treatment with the acid Where no slough formed, a retrograde process was developed by which the infiltration and swelling gradually diminished As soon as healthy granulations sprang up after a slough had been cast off, Krause applied the acid to these, with gratifying results, as attested by a most interesting case In spite of assiduous treatment with approved remedies, the condition in this case had gone on from bad to worse until the parts had all lost their normal configuration, the vocal cords were distorted by excrescences and ulcerations, and swelling existed everywhere, so that deglutition was most difficult Upon the free use of strong solutions of the acid the swelling and œdema disappeared, ulcerations shrank and cicatrized, the vocal cords regained something of their normal smoothness, and the act of swallowing again became possible Submucous infiltration and swelling became most readily absorbed when the acid could be made to reach the parts directly, which was done by scarifying the mucous membrane, if rendered necessary by the absence of ulcerations As might be expected, the results were different according to the location and extent of the local changes, and the general condition of the patient Pain and secretion were always lessened and deglutition made easier

In a word, Krause thinks he has discovered in lactic acid a therapeutic agent by which thickening and œdematous infiltration due to perichondritis can be diminished, excrescences removed, and ulcerations cicatrized and contracted, as in one instance where the vocal cords, notched and ragged, became tolerably smooth and even Where the constitutional disturbance is not too profound and the laryngeal destruction not too deep, the extension of the disease within the larynx can certainly be controlled, and in graver cases, pain can be relieved and the act of swallowing rendered less difficult—even if nothing more can be accomplished In comparison with other therapeutic measures, this is assuredly a great gain Krause has likewise found the acid serviceable in affections of the nose and pharynx attended with hypertrophy and granular degeneration, or tenacious and obstinate secretions

LATENT TALENT IN THE PROFESSION

In the *British Medical Journal*, of August 22, is a very excellent editorial article on "Culture in the Medical Profession" Of it, however, we can only say that it urges upon medical men the importance and benefits to them and to the public of extending, when possible, their accomplishments beyond their professional sphere To a certain extent—and to a large extent, this is true But it would seem that outside work, and outside accomplishments, should be taken up with the view of at some time utilizing them in professional work The list of medical men who have become distinguished in other fields than medicine is long and exceptionally brilliant—but as a rule in these cases they have distinguished themselves more in the outside field than in their proper life-work

It is an unquestionable fact that a man must write if he would be known It is not always the most brilliant man who wins the most reputation, or who has the largest clientèle, nor is it the most steady plodder, who does his work methodically, who is most often quoted as an authority, nor yet is it the man who has a paper for every meeting of his medical society, and one a month for every journal that will give him space But in the greater number of cases it is the man who writes well, and who always has something to say when he writes And this leads up to another matter, which seems to be looked upon very often as an accomplishment, and but too seldom as a necessary accomplishment—a knowledge of the English language, or, more properly speaking, of the mother tongue, for our remark is equally true of writers in other languages It is a curious and lamentable fact that the proper study of the mother-language is neglected in every country Children are pushed into ancient languages and other studies before they can frame a correct sentence in their own language, with the hope, that is but too seldom realized, that they will learn it at a later day The effects of this neglect are but too often seen in the writings of those whose education has been thus abused But we trust that no one will think that we refer especially to Americans in speaking of this matter Americans, as a rule, write as well as their English cousins, and it must be said that both the English and Americans are much less diffuse in writing than the Continental writers

The medical men who will be leaders of medical thought twenty years from to day will be those who commence to write now, and who will *learn* to write later, for it is not to be supposed that anything like perfection in writing will be attained without much labor and study One of the most desirable and useful accomplishments for a physician, therefore, is the ability to write well in his own language—and it should be considered as a necessary accomplishment, as it seems to be no longer regarded a necessity in itself To read and write a foreign language with ease is certainly very desirable, but it should be considered as a matter rather secondary to that of learning the mother tongue, for he who only half knows English, and becomes proficient in French and German (and possibly Italian), will in the end inevitably produce a compound that is neither pleasant nor correct It might almost be said that one can never attain to perfection in writing a language, but such a degree of proficiency may be attained that what is written is pleasing and easily understood We know that the best writers are those who so express themselves that the reader grasps their ideas without direct effort, and it is equally certain that he who can express in one page what another can scarcely crowd into two, has an enormous advantage

Their are hundreds of young men in this country who are allowing talent to lie fallow To them we would say begin to write now, if what you write does not suit you, or does not suit the editor to whom you send it, re write it, for the fault is not in the editor who rejects it, but in the writing—supposing that there is anything of value in the foundation of the article It is a well settled fact that those who become distinguished as writers begin to write early in their professional career It is very seldom that a man will commence to write late in life And as a rule, he who begins to write late in life is much more impatient of having his writings corrected than the young writer Those who write much know that it is a part of the duty of an editor to revise manuscripts, and that he makes corrections equally for the benefit of the writer and of his journal Few editors have the time to revise a paper for the pleasure it gives them—and one who can derive very much pleasure from this work, or who can regard it as a pastime, must have an abnormal view of what constitutes pleasure

There are doubtless some who will think that we are wasting our own and the reader's time in making these suggestions—and it is likely that to many we are speaking to the wind, for it is not difficult to find those who are so well satisfied with themselves that they are as heedless of advice of this kind as they are careless in their use of language There are many who resent any interference on the part of an editor with what they are pleased to term their "English,' but who would be much chagrined, if they really know the language, to see that they have committed such offenses as using "allude" for "mention," "apt" for "likely" or "liable," "preventitive" for "preventive," "instances where" for "cases in which," "diagnose" for "diagnosticate," and a few hundred other common errors, such as capitalizing every other word (except proper names), which could be easily avoided by studying one or two of the many books regarding the use of words—and occasionally consulting a dictionary We have said nothing of the errors in grammar which are so common, for, first, the writer who persistently makes these errors is almost hopelessly lost (as is his reader when he attempts to understand what is written), and, secondly, because when a person has sufficient self-respect, and consideration for others, to be careful in his usage of words, he has already become careful as to the framing of his sentences

There are few physicians who do not see at least two or three cases every year which are worthy to go on record, but the case should be first carefully observed, and then carefully reported It is entirely unnecessary to wait for a case such as has never, or but very rarely, been observed before A careful report of an interesting case of diabetes or phthisis will have many more readers than a report of a case of tylosis of the hands, with half a page of bibliography So, also, the writer who knows when he has finished a paper, and stops at the end, will find more readers than he who writes rather by the amount of paper at his disposal than by the ideas to be presented Lastly, use English words, and a short word when it will serve the purpose of a long one Do not sandwich German and French words in English sentences, as is often done by those who are beginning to learn a foreign language. One who does not know German might think that a new preparation was meant when he reads that a patient was ordered to use an "Opium stuhlzapfchen" at bed-time, and would be disappointed to learn that is only a common opium suppository.

SOCIETY PROCEEDINGS.

MEDICAL SOCIETY OF VIRGINIA.

Sixteenth Annual Session, held September 15, 16 and 17, 1885.

(Concluded from page 415.)

THURSDAY—AFTERNOON SESSION.

After the induction into office of the President-elect, Dr. Rawley W. Martin, the retiring President, Dr. S. K. Jackson, was elected an Honorary Fellow of the Society.

THE REPORT ON ADVANCES ON HYGIENE AND PUBLIC HEALTH

being called for, Dr. Edwards announced the sudden death of the reporter, DR. WM. H. COGGESHALL, of Richmond, Va., on September 7th, just after he had finished his paper. By unanimous vote Dr. Edwards was requested to read the report, as prepared by Dr. Coggeshall, after which it was ordered to be published. His subject was

THE RECENT EPIDEMIC AT PLYMOUTH, PA., AND THE LESSON IT TEACHES.

He gave in detail the history of the epidemic of typhoid fever which has lately so decimated the town, and showed conclusively that from the non-sanitary care of the excreted products of one adult lying sick with a serious attack of the fever, the entire epidemic was traceable. A man living within fifty feet of the bank of the mountain stream from which the residents of Plymouth derive their main supply of drinking water, was taken sick about January 1st, 1885, with typhoid fever, contracted in Philadelphia, and during the months of January, February and March all his dejecta were thrown out—without any precautionary care as regarded disinfection—upon the snow, and in a common country privy without vault or earth-box, where the contents remained for the time simply on the surface of the ground. These two different piles of poisonous excretory matter were not thawed until March 25th, when a warm rain carried the non-disinfected mass into the stream, dissolving it and liberating the hitherto hibernated noxious organisms, and after the usual incubatory period of ten to fifteen days had passed, citizens using hydrant water were taken down with the same disease in different parts of the town, until within ten days from the outbreak, nearly if not quite one thousand people were sick with the fever. During this time not one person using well water was attacked with the malady, but Plymouth having no drainage system except upon the surface, besides having many of its privies constructed without vaults, and being abominably dirty itself, according to all disinterested accounts, the wells soon became polluted with the specific poison germs of the disease, and ceased to yield safe drinking water. No one habitually using Susquehanna river water (near at hand) and employing ordinary care, was stricken down by the malady. One in seven, in a city having a population of about ten thousand, suffered, more or less, from the fever during the epidemic, and over three hundred lost their lives before its finality.

After specifying a number of peculiarities of the malady, the writer offered the following as conclusive lessons taught the profession by this one particular epidemic of typhoid fever:

1. That from an exceedingly small and apparently trivial source of infection, danger to a large number of persons may arise in the course of a zymotic disease.
2. That whatever doubt could previously exist in the mind of any member of the profession regarding the power of previously pure running water to become an active carrier of typhoid infective germs, has by this epidemic been entirely dissipated.
3. That the uncleanliness and non-sanitary condition of a town or city prolongs, in the direct ratio of its extent, the stay of an endemic or epidemic in such place.
4. That during a typhoid epidemic—and especially in its early stages—cases of the disease may, and do, occur where the patient, having proper sanitation at home, receives the poison germs into the system by the simple imbibition of water containing such organisms elsewhere than at home, without his or her knowledge or suspicion.
5. That a town can not afford to remain in an uncleansed condition, however remote danger from zymotic disease may otherwise appear, as such uncleanliness is a direct invitation to certain contagious and infectious diseases to establish a firm foothold in that place.
6. That a typhoid epidemic occurring in a city, once brought into existence from any cause, is easily enlarged and more fully developed by neglect of well-known and easily effected individual and municipal sanitary measures.
7. That the water supply of a town or city—notwithstanding the safeguards commonly thrown around it by the municipality—can easily be transformed, suddenly and unexpectedly, by contamination, into a poisonous condition for the uses of a community, from a source at once remote and individual.
8. That careful and thorough disinfection of the excreted matter—both liquid and solid—voided by a typhoid fever patient, is of the utmost importance to the health of the surrounding community, whether in city or country, but, owing to lack of proper sewerage facilities, especially so in the latter.
9. That the physician practicing in a rural district which is in any manner, remotely or directly, connected with the water supply of a corporation, should exercise more than ordinary precaution to see that such water supply is placed in no danger of receiving

contamination from his patients, either actively or indirectly

10 That although it has been the custom in past years to look upon the water of city wells in general as far more liable to hold contamination from poisonous organisms than water furnished from reservoirs, yet the "Plymouth epidemic" has shown that a condition exactly the reverse may exist

11 That to eliminate all possibility of poisoning in this manner, from sewage or excretory matter, either through carelessness or ignorance, no human habitation should be allowed by law to exist near the source of a city's supply of drinking water

Dr Coggeshall closed by advising his hearers to recommend to the families under their care a more careful study of hygienic questions—so much of the comfort and happiness of life depending on a knowledge of such matters And especially in view of the probable incursion of cholera next summer, he thought a great deal depended on the work done by physicians before that time in educating the people in sanitary knowledge as to whether the scourge shall leave this country in a decimated condition or the reverse

Hon Fellow J E Chancellor, of the University of Virginia, read an interesting paper on the

HISTORY, EVILS AND ADVANTAGES OF INHUMATION AND CREMATION

The subject was opened by reference to the sanitary regulation of this country, the organization of the American Public Health Association and the National Board of Health, the rapid development of sanitation and hygiene They had grown from almost absolute darkness into noonday light, and by this better light we were enabled to detect many of our errors and prejudices which were the accepted facts of the past For centuries past we have been looking through a glass darkly dimmed by errors and sentiment born of heathen superstition and fostered by ignorance No foul vapor polluted the earth beneath or air above, there was no decaying remains of man or beast to poison or destroy life The custom of interment of the human body had been handed down from generation to generation In the progress of time new customs and a new civilization developed, giving rise to different views and faiths as to things beyond the grave, which led indirectly to the disposition of the human body in various ways, viz Exposure, inhumation, embalming, and cremation Reviewing briefly the origin of these, stating incidentally early Egyptians had their Sautterians who, at an early period, detected the germ infection of the living by dead bodies decomposing With the ancients, who believed in the immortality of the body as well as the soul, the disposal of the dead body was made with reference to their belief It was conceded that earth burial with the Greeks and Romans was the more ancient mode, and that our present funeral customs are largely derived from them The Greeks and Romans recognized earlier than any other nation the injurious effects of intra-mural interment, and passed stringent laws prohibiting it The evil effects of the earth burial custom similar to ours were recognized 1600 years ago History teems with proof of epidemics caused by decomposing human bodies, as established by St Augustine and others The investigation made an hundred years ago by Pintolli and Navier (1775) was cited as proof, also those of Ambrose Pare In 1849 the city of London selected a commission of eminent scientists and medical men to examine the city cemeteries Their unanimous report was that they were dangerous to public health and the cause of many severe epidemics This commission, in speaking of the condition of many church-yards, stated that they were abominable, the smell revolting and distinctly perceived in the adjoining houses, in all of which choleraic and diarrhœal disease had occurred Quoting from Sir Henry Thompson, a distinguished sanitarian of London, who had examined nearly a thousand authorities as to the dangers of earth burial, he says that thousands of human lives are cut short by the poison of slowly decaying dead and diseased animal matter

Mr Spencer Wells states that decomposing human remains so pollute the air and water as to diminish the general health and average duration of life Dangers of earth burial were from the contamination of water, the air, and direct infection from exhuming remains and opening vaults, and the elimination of gases, etc Investigations in every age, from Hippocrates to the present, have proved that polluted drinking water is the most frequent source of zymotic disease The yellow fever epidemic in Portsmouth, Va, in 1855, was due to bilge water pumped upon the dock from an infected vessel And the recent epidemic of typhoid fever at Plymouth, Pa, was caused by pollution of the city's water supply from the excreta of a case of typhoid fever near its source What may we not expect from decomposing human bodies in the long used cemeteries and burial grounds of towns and cities Much other testimony was cited to show that the whole list of zymotic and infectious diseases are capable of transmission per the contamination of water and air supplies Soil and air infection was proved by recent investigations of MM Pasteur and Darwin, and also by the investigations of Dr Domingo Freire, of Rio de Janeiro, as to the causes of a recent epidemic of yellow fever in that city He discovered that the soil of the city cemetery in which the victims of this epidemic were buried, was alive with microbian organisms like those found in the emesis and blood of those who had died of the fever Professor Brachi's experience of the plague in Modena, in 1828, showed the effect of soil infection from victims of the plague who were interred three hundred years before The terrible virulence of cholera in London, in 1854, was attributed to the same cause, viz the upturning of the soil where the plague-stricken people were buried two hundred years before The epidemic of yellow fever in New Orleans in 1853, and the great mortality (452 per 1,000 of the population), in the 4th district, was supposed to be due to the proximity of cemeteries in which three thousand bodies had been buried the year before The custom of France, Germany, and Brussels restricting the excavation of wells within certain distance of the place of burial, was alluded to, and regrets expressed that there was no such judicious sanitary regulation in the United States The views of Sir Lyon Playfair, of London, were also cited in proof of soil infection by the dead, giving rise to the "Roman fever" Chemistry and the microscope have assisted in detecting the evils arising from inhumation of the dead, and with the progress of sanitation and hygiene of the present day, pointing out the errors of the past and offering a better and more certain protection to the living, we shall, in the near future, have a less objectionable way of disposing of the dead, which he proceeded to show was cremation, in that it was "safe, secure, permanent, innocuous, and at the same time practical, reverential to the dead, and offering no violence to the feeling and rights of the living"

Cremation of the 19th century was shown to be very different from that practiced by the ancients, a brief history of which was given He was not forgetful of the fact that the public mind, with its prejudices established by long usages and moulded as a semi religious sentiment, was not prepared to receive suddenly any radical change that centuries had endorsed, the demand for it must be made plain, and this must come from the educated and cultured, patient investigators and searchers after truth, those who mould public sentiment in all questions that pertain to the ill or good of their fellow-men Cremation is attracting the attention of men of science and the general public in all countries Sir Henry Thompson has done much to attract the attention of the English and American people to this subject An account was given of its rise and progress, not only in Europe, but also in this country Dr J M Keller, of Arkansas, was mentioned as an able advocate of cremation as a substitute for earth burial, also, Dr W K Curtis, of Chicago, and John Morris, M D, of Baltimore, Rev J D Beagley, of New York, and many of the leading scientists, sanitarians, divines and journalists of the present day From a sanitary point of view, none can doubt that cremation is preferable to sepulture

Dr Philip Taylor, of Richmond, in his

REPORT ON OPHTHALMOLOGY AND OTOLOGY,

mentioned the practical benefits to be derived from the use of jequirity in trachoma, with or without pannus, and insisted on the fact that chronic purulent conjunctivitis should exist when jequirity is used The recent theory of the transmission of sympathetic ophthalmia by means of the intervaginal lymph spaces of the optic nerve was given and conclusions as to the conveyance of the septic poison by the ciliary nerves from the diseased or injured eye to the sound one—the once popular theory—were drawn The use of cocaine was referred to as one of the most important discoveries made in ophthalmology for many years Numerous operations that have been brought to the notice of the profession during the past year, were referred to, notably the one for pterygium, by Dr Prince, of Illinois, another for evisceration of the eye ball as a substitute for enucleation, and also one for transplantation of the cornea in case of considerable opacities of the cornea rendering iridectomy impracticable The danger of the operation for internal strabismus in the young, and making the correction absolute—pointing out the fact that as maturity comes on insufficiency is quite liable to follow, thus causing external squint

In otology some recent preparations for purulent ear trouble were discussed, especially peroxide of hydrogen New Eustachian catheters and the method of using bougies for dilating the tube, was approved The relation between diseases of the teeth and ear was referred to, and statistics given showing that sympathy exists between these organs

Dr Jos A White, of Richmond, read some

CLINICAL NOTES AND PRACTICAL OBSERVATIONS FROM THE RICHMOND EYE, EAR AND THROAT INFIRMARY

(See page 423)

Dr Charles M Shields, of Richmond, read a

REPORT OF CASES OF TRACHEOTOMY IN LUPUS OF THE LARYNX AND DIPHTHERIA

He mentioned the great variety of cases of lupus of the larynx, and selected the case of a retired physician, aged 55 When he first presented himself for examination, his symptoms were loss of voice, some pain in swallowing, and some dyspnœa Laryngoscopic examination showed the epiglottis to be normal in appearance, but revealed a swelling entirely obliterating the right vocal cord and ventricular band. This growth was covered with pale, tuberculous elevations, having between them superficial ulcerations. The left side of the larynx was healthy, except some general thickening and congestion The patient had never had syphilis, there was no phthisis in his family, nor were there any physical or constitutional evidences of phthisis in the patient There was also no history of cancer in his family Thus the three usual causes of laryngeal ulceration, syphilis, phthisis, and cancer, were excluded, and the probability of lupus suggested This view was further sustained by the fact of there having been some skin manifestations of the same disease in the form of two points of ulcerations on the face that resembled lupus, and that would not heal until excised He was treated with iodide of potash and cod liver oil, and by local insufflations of iodoform and bismuth No improvement occurred, however, and he continued to grow worse until about seven months after he first presented himself, and about two years from the beginning of the disease, when the left side of the larynx had become involved, and dyspnœa was so great as to necessitate tracheotomy The larynx now presented the appearance as described by Morell Mackenzie, Cohen, and others, as peculiar to lupus, and the swelling was so great that no glottic aperture was visible Tracheotomy was performed, from which the patient made a good recovery, and obtained relief from dyspnœa He was taught to remove, cleanse and reintroduce his tube, and when heard from the following summer was doing well

He also reported a successful case of tracheotomy for laryngeal diphtheria The patient was a little girl of three years She had, at first, fever and some dyspnœa. The pharynx showed no evidences of inflammation, and was free from membrane. She was hoarse, and continued to breathe with more difficulty. On the third day two small patches of diphtheritic membrane appeared on the tonsil and posterior wall of pharynx, but disappeared in thirty-six hours. Iron, quinine and whisky were administered, and the room kept filled with the vapor of lime. She continued to grow worse, however, and on the fifth day of the attack was so cyanosed that tracheotomy was performed. As soon as the tube was introduced respiration stopped entirely, and artificial respiration was resorted to. For fifteen minutes no effort at natural breathing was made, and on removing the tube a piece of membrane was drawn from the wound which proved to be a perfect cast of the trachea, about two inches long. After this she did well. The wound became covered with diphtheritic membrane. The tube had to be kept in three weeks before breathing through the larynx was sufficiently good to permit its removal. She made a good recovery.

DR. CHAS. R. CULLEN, of Henrico Co., forwarded a paper on

INFANTICIDE.

This paper does not follow the ordinary routine found in the text-books on medico legal jurisprudence, but merely seeks to call attention to the weakness of Virginia laws on the subject. Dr. Wm. H. Taylor, coroner of Richmond City for about thirteen years, furnishes statistics of 139 cases tried for infanticide during his term of office—forty-three whites and ninety-six negroes. Of the total number, not a conviction followed. The laws of England and Scotland have succeeded better. Of sixty eight trials for infanticide, in London, fifty three convictions followed. In New York and Pennsylvania, the laws are much more certain of securing convictions than in Virginia. The very harshness of the Virginia laws causes them to fail of good results. Dr. Cullen reports two cases of trials for infanticide which had come under his notice, showing the weakness of the Virginia laws, and he now calls on the Medical Society to aid in re-framing the State laws relating to infanticide.

Voluntary papers being in order, DR. L. ASHTON, of Falmouth, read a paper entitled

A PLEA FOR TRACHEOTOMY IN CROUP.

The good that is to result from the timely performance of tracheotomy is so great that it should be placed among the minor surgical operations. This classification would materially help to popularize it, and take from it that dread that parents so often have regarding it. The operation, in itself, is comparatively free from danger, but is a delicate one, requiring coolness and caution, and when performed hurriedly, is too often made difficult and dangerous. The operation not being dangerous in itself, nothing connected with its mere performance should influence the time when it is to be resorted to. As soon as it is decided that a positive mechanical obstruction to the entrance of air into the lungs, exists, operate, before secondary complications can occur—such as broncho pneumonia, œdema of the lungs, prostration of nervous energy, etc. In the majority of cases of croup, death results from want of oxygen in the blood. It should be performed in all cases where the croup is progressive and unaffected by medical treatment. In a number of cases, the extension of croup is arrested by tracheotomy. The admission of air into the lungs through an artificial opening in the windpipe secures entire rest for the diseased larynx, and this leads to a suspension of diseased action there. The diphtheritic process, clinically speaking, stops at the level of the vocal cords much oftener than is commonly supposed. When the disease involves the trachea, it is by propagation from the larynx, and not by a simultaneous attack on the larynx, trachea and bronchi, and this extension downwards is generally prevented by early tracheotomy. Since the operation alleviates suffering, mitigates the symptoms, obviates secondary complications, and does not add one element of danger to the original disease, there ought to be no delay to its early performance. Many children have even been brought to life again by it, with the aid of artificial respiration.

EVENING SESSION.

DR. J. S. CONRAD, Superintendent of Matley Hill Sanitarium, near Baltimore, Md., by invitation read a paper on the

PSYCHOLOGICAL ASPECTS OF SUICIDE,

of which the following are the conclusions:

1st. Suicide increases with the advance of civilization, and is but little known in the savage state of men.

2nd. The act is an intelligent act, (?) done with a full consciousness of the act—as shown by the method of execution—whether by the sane or insane.

3rd. That suicide is done always for the purpose of escaping an evil, and for the benefit of the *felo de se*—whether by sane or insane.

4th. That it is a voluntary act, (?) whether by sane or insane.

5th. That it is an emotional act, whether by sane or insane—however deliberately planned and executed—since deliberation enters into the mind of both mental states.

6th. That delusions are not essential to the distinction as to the sanity or insanity of the suicide, since authorities affirm that delusions are not essential to the proof of insanity.

7th. That suicide is rare in the first class. Insanity (by Maudsley) viz. intellectual or ideational insanity; but does occur in the vast majority of the second class—or affective or emotional forms of insanity.

8th. Query? Is suicide an intellectual act—notwithstanding the intelligence exercised in its execution? or is it an emotional act *per se*, since we have seen that the emotional part of mind dominates the ideational centres, and perverts the mind into becoming its humble servant.

9th. Does moral depravity satisfactorily account for it, when we have seen that moral depravity is a factor of both sane and insane?

10th. That in doubtful cases of the sanity or insanity of the *felo de se*, very great caution is necessary in making up a just judgment as to the one or the other

Dr Archer Atkinson, of Baltimore, being present by invitation, read a paper on

IRRITABLE RECTUM,

embracing the very many causes of this distressing trouble, such as the great vascularity of the part, the abundant nervous supply from the cerebro-spinal and from the sympathetic system of nerves, and the frequent sources of congestion from riding, dampness, and from the irregularity of emptying the bowels, especially in the travelling classes He dwelt at some little length on the anatomical relations of the part to the urethra, the prostate gland and neck of the bladder in male subjects, and on its proximity to the bladder, vagina, and the uterus in the female The speaker referred to the efficacy of carbolic acid injections into the body of hæmorrhoids, and of the advantage of combining tincture of opium injections with the fluid extract of krameria with glycerine, to prevent as well as to allay tenesmus of the bowel and to favor reduction of the hæmorrhoidal mass and of the thickened mucous membrane A clinical case was given of a lady over 60 years of age in whom the artery of a large bleeding hæmorrhoidal tumor was ligated in a novel manner, the vessel having been rather felt than seen nearly an inch up the bowel, in the midst of a large growth, was embraced between the two ends of a stout carbolized ligature, the needle having been entered to the side of the centre of the mass and brought out on the other side, the loop including a portion of varicosed substance about one-fourth of an inch in thickness After the removal of the ligature on the seventh day, the bowel was freely washed out, and the mass came away with the returning fluid, since which time the patient has done well, and been free from the *pelvic irritation* from which she has suffered for many years

Dr Wm G Eggleston, of Chicago, Ill , reported a case of

GUNSHOT WOUND OF THE HAND

C H G , a physician, æt 33 years, received an extensive laceration of the left hand while removing the cap from a loaded cartridge containing shot The shell exploded, and the entire charge, so far as is known, passed through the hand The wound extended, on the palmar surface, from a point immediately anterior to the normal situation of the deep palmar arch, between the metacarpal bones of the middle and third fingers tearing the hand completely open thence through to the webbed junction of these fingers, tearing the flesh from the first phalanx of the third finger, save a small portion on the dorsal aspect, and breaking the first phalanx of this finger, and the metacarpal bones of the third and little fingers about the middle third

The wound was thoroughly cleansed with hot water, the clots removed, flaxen sutures put in place, compresses placed over the palmar and dorsal wounds, and the whole metacarpal portion of the hand bandaged somewhat tightly with short bandages, to facilitate removal in case of hæmorrhage The broken third finger was tied to the middle finger, to serve as a natural splint Turpentine was then injected into the wound, and the bandages thoroughly soaked with it Subsequently a drainage tube was put in, and the wound washed out twice daily with a 1–3800 solution of bichloride of mercury

Seven months afterwards, the patient reported that the third finger was practically useless, but that he could do all he wished with the hand, "the grip is good, and the stiff finger seldom getting in my way " In conclusion, Dr Eggleston remarked that it seemed that the third finger (the one most injured) should have been removed, together with a portion of its metacarpal bone

Dr W R Cushing, of Shawsville, read a paper on

PREMATURE LIVE BIRTH WITH THE MEMBRANE INTACT

After reporting a case, in which the child lived some sixteen hours, he called attention to the effect that the possibility of such births must have upon the lung test in deciding whether a child was born alive or not Persons heretofore tried for infanticide have been admitted to be innocent whenever it could be proven that the child had never breathed But in such a case as he here reports, the child could have been deliberately killed after being removed entirely from the mother, and still the condition of the lungs not only would not have testified against the party accused, but would have been admitted as conclusive evidence of innocence

Dr Wm D Hooper, of Liberty, reported a

CASE OF IRRITATION OF THE GANGLION OF REMAK, OR THE INHIBITORY NERVE OF THE HEART

cured by nicotin, according to the suggestions made by Prof Rulliford, of London, in the *London Lancet* It was administered by getting the patient to smoke tobacco While using his first pipe, the blueness faded from his extremities, and the œdema soon subsided to an appreciable extent, and instead of the usual effects of the "first pipe," he felt better at the end than he did at the commencement of it At the end of two weeks of the use of tobacco smoking, the attacks ceased, and he has remained in perfect health since, and is now an active practitioner of medicine in one of our inland towns

Dr Wm C Dabney, of Charlottesville, read a paper on the

PHYSIOLOGICAL AND THERAPEUTICAL ACTION OF ANTIPYRIN

After stating that it was first prepared by the action of acetic acid on aniline, and then giving its physical description, he then mentioned that in healthy persons it causes little or no depression of temperature when a dose of thirty grains is given The frequency of respiration is not affected, but the pulse is always diminished in frequency It generally produces perspiration in healthy persons, and nearly always causes profuse sweating in pyretic individuals The urinary secretion is usually slightly diminished It is eliminated by the kidneys, and is readily detected by the intense red color produced by the addition of a few drops of a solution of perchloride of iron It probably produces its antipyretic effect by direct action on the thermogenic centres in the brain

It is not markedly efficacious in pneumonia, though in some cases it acts admirably Use it cautiously when the time for defervescence approaches lest collapse occur In typhoid fever, two doses of ʒss each at an hour's interval, usually produces a fall of 2° or 3°, which lasts from six to twelve hours, but the course of the disease does not seem to be modified by it, except that it soothes the patient and he drops off to sleep It lessens delirium, too, to a considerable degree It acts favorable upon the nervous symptoms generally, and it also cleans up the tongue It is generally conceded to be useless in remittent fever In puerperal septicæmia, it gives good results —reducing the fever to normal temperature from 105° Dr Boldt, of New York, gave sixty grains in two cases, causing a semi-comatose condition and ' symptoms resembling those of carbolic acid poisoning " In scarlet fever, favorable results are reported, —especially delaying the appearance of the eruption Some say that in phthisis, it has given better results than all other antipyretic remedies combined Others think its desirability in phthisis is questionable It should be given with great caution in this disease for fear of inducing collapse Agaricine or atropia prevents its producing too much sweating It acts unfavorably in pregnant women The unpleasant effects of antipyrin are collapse, and an eruption much like that of measles The dose of antipyrin differs according to the disease In phthisis, from eight to fifteen grains, repeated every four to six hours, is sufficient In typhoid fever, pneumonia, and the like, it has been recommended to give two doses of thirty grains each at an interval of an hour, and an hour later still, give fifteen grains more, but more recently excellent results have followed doses of ten or fifteen grains every three or four hours In children, the dose is a grain and a half for each year of the child's age It may be given hypodermically in doses of from ten to fifteen grains, or by enema in doses of forty to sixty grains When used as a suppository, it is said to have an excellent effect on hæmorrhoids

Honorary Fellow, Dr J M Toner, of Washington, D C, contributed *A Sketch of the life of Dr Elisha Cullen Dick of Alexandria, Va, One of the Consulting Physicians in the Last Sickness of General Washington*, which was received with a vote of thanks and ordered to be published in the forthcoming volume of *Transactions*

Adjourned to meet in Fredericksburg, Va, during November, 1886

AMERICAN GYNÆCOLOGICAL SOCIETY

Tenth Annual Session, held at Washington, Sept 22, 23, and 24, 1885

TUESDAY, SEPTEMBER 22—FIRST DAY

The Society was called to order by the President, William T Howard, M D, of Baltimore

Dr Samuel C Busey, of Washington, delivered the *Address of Welcome*

Dr Busey then read a paper on

THE NATURAL HYGIENE OF THE CHILD-BEARING LIFE

The hygiene of pregnancy related to the preservation of the health of the woman during those periods intervening between conception and the commencement of labor The processes of transformation, development and growth which take place are physiological, but are nevetheless terminated with more or less injury to both mother and child The unavoidable mortality is however, small The process of waste and repair, of growth and development, of organization and construction were next considered There is no border line of health We can not define where the physiological ends and the pathological begins The child-bearing period begins with puberty and ends with the expiration of the years of maturity Fertility increases from the commencement of the child bearing period until the climax is reached, and then declines to its extinction The age of greatest safety of pregnancy coincides with the age of greatest fecundity Beyond and under, the mortality increases with the increase and diminution of age, but the rate is higher with the increase beyond, than with the diminution below the age of maximum safety or least mortality The age of nubility, should correspond with the ages of maximum fecundity, fertility, and least mortality Puberty and nubility are not simultaneous Too early pregnancies were deprecated The speaker thought that nature presented the fifth quinquinial as the period during which the laws of fecundity, nubility and survival find their natural complement in relatively highest perfection He considered first, pregnancies, as the most dangerous, and thought that the danger increased by too early and too late primiparity The importance of lactation was next discussed

The extinction of the child bearing function protects the remaining vital forces from decay, but if the seeds of disease have already been sown, the change of life may increase their activity The author thought that if the age of majority for women could be advanced so as to correspond with the first year of the period of maximum fecundity, popular prejudice and love of custom would sooner or later conform fashion to the law He deprecated precocious matrimony and considered it the sequel of precocious puberty In this country and in the higher walks of life, the ratio of precocious matrimony is on the increase, whether it be equally so among the middle and lower cases, he did not know He concluded by saying that, the principal object of his paper was to direct attention to this subject, and to invite discussion upon it

Dr James R Chadwick, of Boston, stated that he had made a few investigations in regard to the early appearance of menstruation with reference to women of various nationalities in this country In the examination of over 4000 cases, it was found that American women menstruated earlier than women of other nationalities examined Furthermore, American women of American parentage began to menstruate earlier than American women of foreign parentage Scarcely enough observations in reference to the menopause have been made to justify absolute conclusions, but he found to his surprise that the menopause is appearing later in American women If this is corroborated, the conclusion would be that the child bearing period is greater in American women than in women of other countries The fact that the child bearing period is increased both at the beginning and the end, he considered an indication of added vigor There is no question of the fact that the number of children to a family is diminishing, but this can be accounted for by social influences and is common to all civilized communities

Dr Reynolds, of Boston, agreed entirely with the statement made by the last speaker, and he believed that in the community in which he lives, the women of the upper and middle classes menstruate earlier than they did twenty-five years ago He also believed that this indicates an activity of function, which will prolong it beyond the average period of cessation

A point of interest is in reference to the diminution of sexual power He questioned whether this is not more dependent on individuality than on sex He thinks it doubtful that women pass the period for the relation of marriage and of child bearing sooner than men pass the period of procreation This is, however, a most perplexing and obscure question

Dr Henry J Garrigues, of New York, read a paper on

PUERPERAL DIPHTHERIA

This is a disease not referred to in the majority of text books It is one of the forms of puerperal fever, or rather one of the different diseases included under that term It is distinguished by the appearance of diphtheritic exudation somewhere in the genital tract of the puerperal women It is accompanied by well marked general symptoms, imperils life and calls for active treatment The paper is based upon twenty seven cases treated in hospital practice, and two cases occuring in private practice The characteristic feature of the disease is the diphtheritic infiltration which is usually of light pearl-gray color Generally appearing in small spots, and coalescing or extending by involving new areas, the exudation is firmly adherent to and imbedded in the underlying tissue It is most marked at the points where the canal becomes narrow This may be explained by the more frequent occurrence of lacerations at this point The posterior wall of the vagina is more commonly attacked than the anterior wall, which is probably due to the fact that it is bathed with the discharges from the uterus The exudation may, however, appear on entirely healthy portions of mucous membrane, which have not been the seat of laceration The surrounding parts are more or less swollen The connective tissue of the pelvis is infiltrated with serous fluid, and is sometimes the seat of a dusky erythema, consisting of minute spots, disappearing on pressure and not elevated In one case petechiæ as large as hempseed existed These were not affected by pressure The same patient later developed erysipelas

In five cases ending fatally autopsies were made The uterus was much enlarged, sometimes reaching almost to the umbilicus two weeks after labor The cervix may be torn, showing diphtheritic patches or a thin gray film In two cases, large portions of the cervix sloughed and the vagina became gangrenous The tissue of the uterus is friable, and may be almost diffluent The diphtheritic exudation may effect the fallopian tubes In some cases, the muscular tissue of the uterus is scooped out as in dissecting typhus, of which I have described several cases This occured in four of the cases of puerperal diphtheria In one case, the mass thrown off was four inches long, two inches wide and one inch thick These masses have a pear shape, their outer surface is of a gray color, and the inner surface flesh color They are perforated with a number of holes leading into uterine sinuses Under the microscope, these masses are shown to consist of smooth muscular fibre in a more or less advanced state of fatty degeneration The connective tissue is increased Lesions were also found in other organs and occasionally in the joints Difficult labors and a previous weakened condition of the patient predispose to the development of the condition The real cause of the disease is, however, an infection from the outside I have never been able to convince myself that the poison passes from one patient to another, but it seems to be in the air of the ward When a ward has been fumigated with sulphurous acid, there would not be a seriously sick patient for weeks That the poison comes from the outside is also shown, by the fact, that when the prophylactic treatment to which I shall refer is adopted, the disease does not develop

The first symptom which shows a deviation from a normal course, is usually the occurrence of fever, which mostly appears from two to four days after delivery Sometimes there will be a chill or chilly feeling The temperature rises gradually as a rule It has ranged from 100 6° to 107°, the average being from 102° to 104° Anorexia, vomiting, coated tongue and diarrhœa, witness the disturbance of the gastro intestinal canal The patient complains of pain in the epigastrium and one or both groins, sometimes extending into the legs Examination shows the uterus larger than it should be, and quite tender Tenderness is often also found in the groins and some swelling may also be observed The lochial discharge is often scanty and offensive, but in some cases it has been normal In those cases in which there was expulsion of the tissues of the uterus, there has been a purulent discharge until expulsion has been accomplished The diphtheritic patch general appears from three to seven days after delivery It continues to spread for several days and usually stops in from three to eight days after the beginning of treatment In one case the diphtheritic patches also appeared on the tongue, indicating that the disease is identical with the ordinary form of diphtheria attacking the throat The irritation of the nervous system is evidenced by headache, stupor and delirium There is alteration of the renal secretion, and sometimes there is painful micturition Three patients had albuminuria In two cases jaundice bore testimony to the perverted condition of the blood The sweet breath and profuse sweats of septicæmia were observed twice. One patient developed painful arthritis of the elbow joint. When the diphtheritic process was once arrested, the patients recovered rapidly. There is scarcely any difficulty in the diagnosis. When the injections of bichloride of mercury are employed, they cause a yellow discoloration of abraded surfaces. This is strictly limited to the abraded surface, and is unaccompanied with general symptoms. When the chloride of zinc is applied to the affected surface in the treatment of the disease, a slough is caused, having the color of the deposit and the physician is sometimes at a loss to determine whether or not the disease is spreading. The point is decided by noting where the application is made, and by observing the edge of the deposit. The diphtheritic deposit has a scalloped outline while the outline of the slough is smooth.

As to prognosis five out of twenty nine cases died, giving a mortality of 17.2 per cent. Another of the cases might have survived, for she lived thirty-two days, and died from rupture of the uterus while an assistant was using an intra uterine injection. The post-mortem showed the walls of the uterus to be extremly thin. The duration of the cases ending recovery, is usually about two weeks. In those cases in which a portion of the uterus is scooped out, the organ is left in a weakened condition, which in future pregnancies may predispose to rupture of the uterus.

In the way of prophylaxis, it is recommended to limit the vaginal examination during labor as much as possible. The finger or hand should not be introduced into the uterus unless absolutely necessary. The delivery should be so accomplished as to avoid as much as possible wounding of the genital canal. Instruments should be used with care. The most important element in the prophylaxis is the use of bichloride of mercury as an antiseptic. Everthing coming in contact with the patient should be washed in the solution of corrosive sublimate, one to two thousand. After this treatment was introduced only one case appeared in six months, and that was due to carelessness on the part of a resident who delivered a woman immediately after removing a macerated fœtus from another patient. After the disease appears, the treatment must be energetic. The only treatment that has given me satisfaction, is that with chloride of zinc. The affected parts are touched with a solution consisting of equal parts of chloride of zinc and distilled water. This is rather painful and an anæsthetic may be used. A warm solution of corrosive sublimate, one to two thousand is used for intra-uterine injection where this is required, and subsequently a suppository of fifteen grains of iodoform is introduced. If this is done the process need not be repeated more than once in the twenty-four hours. The vagina is to be douched every three hours. The parts should be examined every day, and if the process is not arrested, the chloride of zinc is to be repeated. If the disease be limited to the vagina and vulva, *the intra-uterine treatment* is omitted. Extract of ergot is also given, with the hope of causing contraction of the uterus. Morphia, quinia and digitalis are used as indicated. High temperature is combated with sponge bathing, salicylic acid, and if necessary, the rubber coil and ice water. Carbolic acid is also given, sometimes combined with the compound tincture of iodine. If the temperature be not very high, warm poultices are preferred to the ice bag and coil. Where there is diarrhœa, warm poultices are also considered preferable.

Samples of the occlusion bandage to be used after labor, were exhibited. They consisted of a pad of absorbent cotton wet with the corrosive sublimate solution, over this a piece of oiled muslin or rubber cloth, and over all, a piece of absorbent cotton and a piece of muslin or flannel to attach it to the binder.

Dr. Wm. T. Lusk, of New York, said that ten years ago he had one hundred and fifty cases of this affection under his care. Of this number twenty eight died. The epidemic could be traced to a patient brought into the hospital after a long labor. She was suffering at the time from syphilitic ulcers of the vulva, which was excessively inflamed. He delivered with forceps and the inflamed perineum tore. Soon after this the diphtheritic deposit appeared, and the whole ward was infected. The first cases were the result of transference from the patient, for the question of contagion was not recognized as it is now. After a time great care was taken to avoid every possible source of contact, but the disease continued, and could be only explained on the supposition that the air of the ward was filled with germs. In his first cases the treatment consisted in the application of equal parts of the solution of the persulphate of iron and compound tincture of iodine. The disease usually began with a certain amount of mildness, and gradually became more severe. Of the first twelve cases only two died, while in the second set of twelve cases only two recovered. In the progress of the epidemic the entire system seemed to be affected, even before the advent of labor. Since the adoption of Dr. Garrigue's suggestion with reference to the use of corrosive sublimate injections, he had not seen a case of puerperal diphtheria in the course of three and a half years. He had neither had a death from fever nor any cases of fever, the old fashioned milk fever even being absent.

Dr. H. P. C. Wilson, of Baltimore, remarked that he had always been adverse to using bandages of any kind after delivery, preferring to have the napkins placed under the patient so as not to obstruct the free flow of the discharge and to use frequent washing of the vagina with antiseptic solutions.

Dr. Richardson, of Boston, said that during the years 1882 and 1883 he had treated many cases of puerperal fever, but with ill success until the appearance of Dr. Garrigue's paper. After adopting the use of the pad and the corrosive sublimate solution for the hands of the attendants and nurses, the hospital has been almost entirely free from the disease. There had been no death since he adopted these measures, and there has been only one or two cases which had caused any anxiety. He agreed entirely with what the reader of the paper had said. He had found that even so weak a solution of corrosive sublimate as one to five thousand will sometimes cause salivation. Where this occurs he uses iodoform, as has been suggested.

Dr. **Burns**, of Brooklyn, inquired of Dr. Garrigues whether he had noticed any vaginal deformity following this affection? He had seen one case in which such deformity occurred. A lady, after her fifth confinement, was taken with tenderness, fever, and so on, and on the fourteenth day had a copious hæmorrhage. On examination, he found the entire posterior and outer surface of the vagina almost completely detached. Acetic acid was applied and the bleeding checked. An examination after the healing of the parts had taken place, showed the vagina much shortened and narrowed in its upper part, the cervix being obliterated. The anterior portion of the cervix was in contact with the recto vaginal septum. He told the patient, in reply to her inquiry, that it was not likely that she would conceive. His prediction turned out to be false. In the following confinement, she was in labor twenty four hours before there was the slightest appearance of an opening through which a fœtus could escape. There was bulging of the presenting portion of the uterus, and into this he made an incision and the child was delivered readily, the patient making a rapid recovery.

Dr. **Garrigues** thought that the endorsement of Drs. Lusk and Richardson would be sufficient to induce others to try the occlusion pads. During the year preceding the introduction of the new method of treatment, the mortality was nearly seven per cent. During the next, with the new method of treatment, the mortality was one and a half per cent. During the second year, it was less than three fourths of one per cent. In the institution in which these observations were made there are a number of disturbing elements, one of the most important being its connection with a large general hospital. In this new method of treatment the antiseptics are applied only to the outside in normal cases. Only in abnormal cases are vaginal and intra-uterine injections employed. In reply to the objection of Dr. Wilson, he said that the pads used are absorbent. In hospital practice the pad is changed every four hours. In private practice, three times a day is sufficient. He had never seen salivation from the use of corrosive chloride. The nearest approach to it had been fœtid breath and diarrhœa. He had only seen two of the cases subsequently to recovery when in labor. In one there was great shortening and narrowing, but during pregnancy there was softening, and the labor was quite easy. The second patient is pregnant, and the vagina appears to be in good condition.

In reply to a question, the speaker stated that the use of the pads prevented all offensive odor.

(*To be concluded.*)

DOMESTIC CORRESPONDENCE

NEW YORK LETTER

(FROM OUR OWN CORRESPONDENT.)

Dr. Jacobi's Address before the Academy of Medicine—Obscure Cases of Weak Heart—Death during an Epileptic Fit.

The address with which Dr. Jacobi, the President, greeted the Fellows of the Academy of Medicine when they reassembled for the first time after the summer vacation, on the evening of October 1, while very excellent in many respects, was marred by an expression of sentiment in regard to the "Code question," which was, to say the least, in very questionable taste, and which could not but prove offensive to a considerable portion of his hearers. Quite a large part of the address was devoted to a glorification of the action of the New York State Medical Society in repudiating the National Code, against which the adherents of the latter so long protested and so gallantly did battle, and just why such a firebrand should have been introduced, like a thunderclap out of a clear sky, at the very beginning of the scientific work of the Academy for another year, it is not a little difficult to understand. This body is made up of old and new Code men alike, but the action of the latter in the past has deprived it of the support of many of its former devoted friends, so that quite a number of those who used to be most active in its work, and who are by far the most liberal benefactors which it ever had, are now never seen within its walls. The unwise proceeding of Dr. Jacobi cannot but have the effect of still further alienating the adherents of the National Code, and thus proving directly prejudicial to the best interests of the Academy.

Having referred to the recent explanatory declaration of the American Medical Association in regard to certain clauses of the Code of Ethics at the New Orleans meeting, he went on to say: "The expressions of opinion in regard to the wholesome effect of the New Orleans declaration have been very numerous. I am in possession of several letters containing remarks full of satisfaction and hope. A gentleman well and deservedly known in the profession of both hemispheres, and markedly so with us for his allegiance to the Code of Ethics of the American Medical Association, gave enthusiastic expression to his delight over the satisfaction that declaration must give, and to the hope that the New York Academy of Medicine would give a public utterance in that direction. That would 'immediately settle all difficulty about the Code, and at once restore peace and harmony in the profession.' I had to tell him that the Academy of Medicine excluded all politics, ethical and otherwise, from its discussions, and that the only societies who could act in the matter were the medical societies of the county and of the State of New York. There the matter then rested, for I believe I was right in excluding it from any consideration in our midst." Yet in the face of this assertion, why in the name of common sense does he proceed to drag in the subject by the neck and ears? Apparently the only reason is that the "New Code" may flap its little freshly-fledged wings in jubilation over the "unexpected success on the part of the profession (?) of the State of New York in harmonizing a large majority of the medical men of the United States." "For the Medical Society of the State of New York," he says, "it must be a source of intense gratification to be convinced by the passing of that declaration, that a few years have been sufficient to so change public opinion as to oblige even the American Medical Association to recognize the justness of most of the New York proceedings."

Dr. Jacobi maintains that the clause of the New Code which states that "members of the Medical Society of the State of New York, and of the medical societies in affiliation therewith, may meet in consultation legally qualified practitioners of medicine," is practically identical with the explanatory declaration passed at New Orleans, which he believes "endorses the New York Society and the spirit of the New Code," but if he or any other of the New Code party will make the trial of seeking admission to the American Medical Association as a delegate, offering his allegiance to the New York Code as a substitute for subscription to that of the Association, he will find out that there is a *decided* difference between the two. The American Medical Association stands today where it has always stood. If black is the same as white, then the expression of the New York Code, "may meet in consultation," is the same as that of the explanatory declaration of New Orleans: "No circumstances can make it necessary or proper to enter into formal professional consultations with those who have voluntarily disconnected themselves from the regular medical profession." The cry of "humanity" was only the subterfuge under which the concocters of the "New Code" disguised their audacious schemes. Practically, the point has always been thoroughly well understood by the profession which has now been formally interpreted in the following words of the explanatory declaration: "*Resolved*, That there is no provision in the National Code of Medical Ethics in any way inconsistent with the broadest dictates of humanity, and that the article of the Code which relates to consultations cannot be correctly interpreted as interdicting, under any circumstances, the rendering of professional services whenever there is pressing or immediate need of them. On the contrary, to meet the emergencies caused by disease or accident, and to give a helping hand to the distressed without unnecessary delay, is a duty fully enjoined on every member of the profession, both by the letter and the spirit of the entire Code." If the New York Code and that of the Association, with this official interpretation, mean the same thing, why do not the New Code men renew their allegiance to the latter? Alas, it is not the "emergency-consultations" that they pine for, but those in cold blood which will enable them, particularly if they are specialists, to pocket a comfortable portion of the filthy lucre of the guileless homœopath's affluent patient. It may be true that the homœopaths of to day are very different from those of forty years ago, and that they no longer believe in the principles laid down by Hahnemann, but if, as Dr. Jacobi says, "they now claim that their practice is not based on an exclusive dogma," why do they not drop the empty name, and call themselves simply physicians, in accordance with the broad, catholic spirit of the regular profession? Alas, here again comes in the question of the loaves and fishes! In every community there is a large class with more money than brains, who are never content unless they are being humbugged, and hence the name is retained simply as a device to secure trade. Truly a noble end in men of a learned profession! Let them discard an appellation which implies, at all events, an exclusive dogma, and the American Medical Association will be only too glad to extend to every one of them who is a properly educated physician the right hand of fellowship.

The first part of Dr. Jacobi's address, which was devoted to a consideration of the work of the Committee for Collective Investigation of Disease of the International Medical Congress of 1884, was in every way admirable, and he clearly set forth the difficulties to be encountered and the advantages to be gained in prosecuting labors of this kind.

The scientific paper of the evening, by Dr. R. Van Santvoord, which bore the title, "Obscure Cases of Weak Heart," was devoted to a plea, justified by the narration of several cases of interest, for a more careful study of cardiac weakness and its causes on the part of the general practitioner. The discussion which followed was participated in by Drs. E. Darwin Hudson, Andrew H. Smith, Leonard Weber, John P. Garrish and others. Before adjourning, a clinical thermometer formerly belonging to the late Dr. John W. Francis, of this city, sent by his son, Dr. Francis, of Newport, R. I., was presented to the Academy. It was stated that, so far as could be ascertained, the instrument was made about the year 1830, and Dr. Jacobi remarked that if this claim could be substantiated, Dr. Francis would be entitled to a priority in the use of the thermometer of which any one might well be proud.

A very curious accident recently caused the death of a young man in this city. He was subject to epileptic fits, and always slept with a chair backed up to his bed, to prevent his falling out in case of an attack. On Sunday night last he had a fit, and, falling out of bed, notwithstanding the presence of the chair, his chin struck upon its seat, and his body remaining in this position, he strangled to death before recovering consciousness.

P. B. P.

New York, Oct. 2, 1885.

THE AXIS-TRACTION FORCEPS—A CORRECTION.

To THE EDITOR OF THE JOURNAL:

Dear Sir:—1. In an editorial which appeared in your JOURNAL of Sept. 26, under the title "Dr. Felsenreich's Modification of Alexander Simpson's Axis-Traction Forceps," you state that in my article, "An Obstetric Forceps," published in the September number of the *American Journal of Obstetrics*, my "allusion to the fact" that Dr. Felsenreich, of Vienna, had previously designed all the good qualities of the instrument therein described, "is disingenuous."

2. You further state that "Dr. Felsenreich's instrument is identical with the forceps described by Dr. Neale, with the exception of the thumb screw," and that "Dr. Neale is entitled to the honor of substituting the compression thumb screw at the ends of the handles, for the more useful contrivance of the Felsenreich and Alexander Simpson instrument," in

which the compression screw "is located on the middle third of the superior surface of the handles"

My reply is as follows

1 I purposely refrained from attaching my name to the instrument in dispute I did not call it Neale's forceps, but on the contrary I plainly stated in text, and demonstrated by diagrams, that it is "the practically unaltered Simpson forceps," that Tarnier's "principle of axis-traction is the most important modification of the forceps that has been devised within the past quarter of a century," and that this axis traction is applied to this forceps by means of the button-hole joint which "was first shown to me by Dr Felsenreich, first assistant to Prof Carl Braun, of the Vienna clinic, in 1882," and hence "the idea of the construction" of the forceps "is not *entirely* original with me"

2 I was and am of the opinion (which I grant may be erroneous) that Dr Felsenreich attached the axis traction rods to Braun's forceps, which is considerably different from the Sir J Y Simpson or the Alexander Simpson instrument, but be this as it may, the compression thumb screw in the model of Dr Felsenreich's forceps, I saw in Vienna, in 1882, was Braun's thumb screw (the same as in Braun's cranioclast), attached to the ends of the handles, permanently effecting their shape, and in my humble opinion, their usefulness If there be a later model of Dr Felsenreich's forceps, of which I am ignorant, in which the thumb screw, as you say, "is located on the middle third of the superior surface of the handles, as in the Alexander Simpson instrument" (originally in Tarnier's), I still maintain that even this arrangement permanently affects the shape of the handles and decidedly interferes with grasping them in the hand, as is done when the forceps is used as a simple Simpson, and not as a Tarnier Indeed, this is the very practical objection my entirely detachable thumb screw is designed to overcome, and it does it effectually

3 I have also shortened the shoulder and made the last knob on the hard rubber handles of the disputed forceps more prominent than in Braun's or Felsenreich's, or Alexander Simpson's, in order to afford a better purchase to the grasping hand, or a firmer grip

4 I am of the opinion, not positive, however, that the cross bar handle to the traction rods of Dr Felsenreich's instrument was attached after a method different from the Tarnier model, whereas I adopted this old style with certain slight yet practical alterations, to wit the movable metallic ring fixed to the handle is beveled, not flat, and fits into correspondingly beveled spring shoulders in the ends of the traction rods, which shoulders are two in number, and not one, as in Tarnier's forceps These alterations, without in the least complicating the instrument, render it practically impossible to pull the handle off the rods (unless the springs are purposely compressed), which can not be said of the original Tarnier pattern

5 There is also a fixation bar concealed in the handle to the traction rods, which may be used at option to fix the swivel joint, thereby rendering the entire forceps rigid, when "rotation may be governed (so far as lies in the power of the operator with any instrument) without touching the handles of the introduced blades, or in any way interfering with their action as an indicating needle," Consider this an improvement or not, I have certainly never heard of or seen it in any other forceps

The first blades I adopted were fashioned after the Sir J Y Simpson pattern after shortening the fenestrae and thickening the metal about the button-hole perforation Fearing, however, that these blades might feather or slip, I quickly substituted the Alexander Simpson model, which is of altogether stronger build and greater cephalic and pelvic curves, and this is the only form of the disputed instrument now sold in this city I was under the opinion, which I candidly acknowledge may be erroneous, that Dr Felsenreich adopted Braun's blades, but whether he did or not it matters very little, for I believe Alexander Simpson was the first to attach Tarnier's traction rods to his own forceps, and hence to him is justly due the honor of this part of the modification

1 The shape of the handles, 2 the neat compression thumb screw entirely removable without altering in the least the shape or utility of the handles, 3 the firmer attachment of the handle to the traction rods, 4 the fixation bar concealed in that handle, to be used or not, at option, to aid rotation, are all that I claim If concise nomenclature be desirable you may call it the Tarnier-Alexander Simpson-Felsenreich Neale (?) forceps, but I would suggest the simpler name of "Combination Forceps"

Respectfully, L E Neale, M D

Baltimore, October 2d, 1885

[Dr Neale admits that the forceps, described by him in the September number, current year, of the *American Journal of Obstetrics*, is merely a modification of Felsenreich's adaptation of Alexander Simpson's axis traction forceps He did not mention this fact, however, in the paper to which we have referred We are of the opinion that this omission, to say the least, was disingenuous We experience difficulty in believing that such an acute and attentive student, as Dr Neale was in Vienna, could forget that Dr Felsenreich substituted the button-hole for the hinge-joint in the Alexander Simpson instrument Dr Felsenreich repeatedly called the attention of all the gentlemen, who studied with him, to the characters of the modified instrument The forceps, to which the axis traction rods were attached, was the *Wiener Schulzange*, the original model of the Sir James Y Simpson instrument Carl Braun's forceps has been for years a practically obsolete instrument It never attained to great popularity, and is not used in the Vienna lying-in clinics, except, on rare occasions, by the inventor himself

' Braun's forceps is simply the Sir James Y Simpson instrument, with the fenestrae obliterated and completely covered with hard rubber It would be difficult, if not impossible, to attach axis traction rods to such an instrument

As to the value of Dr Neale's additions and modifications, opinions differ In our judgment, where these additions do not positively impair the usefulness of the instrument, they are utterly trivial

Finally, we have entered into communication with Dr Felsenreich on the subject of Dr Neale's paper, and hope, within eight weeks, to publish his own comments Ed]

ASSOCIATION ITEMS

INFORMATION OF IMPORTANCE TO ALL MEMBERS OF THE AMERICAN MEDICAL ASSOCIATION

To the Editor of the Journal

Dear Sir —The notices which I send to members for payment of their annual dues bring to me so many inquiries as to the rules and customs of the Association, that I have deemed it advisable to call the attention of all your readers, as briefly as possible, to their responsibilities to the Association, viewed from my standpoint as Treasurer

Membership —Every one who attends an annual meeting of the Association as a delegate pays at that time five dollars, and thenceforward becomes a Permanent Member He continues as such as long as he remains in good standing in the body from which he was originally sent as a delegate As a Permanent Member, he must pay *Five Dollars Annually*, when notified by the Treasurer, whether he attends the meetings of the Association or not Payment of annual dues entitles him to receive the weekly Journal of the Association for one year

Members by Application are such as have not become Permanent Members in the manner above indicated, but apply to the Treasurer for membership, forwarding at the same time to him five dollars and the certificate of the President and Secretary of their State or local society, that they are in good standing in such society They pay five dollars annually thereafter, when notified by the Treasurer Members by application can join the Association at any time, and they receive regularly the weekly Journal

When Dues are Payable —The annual dues from Permanent Members are payable to the Treasurer at the time of the annual meeting of the Association, or immediately thereafter The payment entitles the member to receive the Journal for one year from the following July Payment for 1885, for example, entitles the member to the Journal from July, 1885, to June, 1886, inclusive

As some of the members have not yet forwarded to the Treasurer their dues for 1885, they are urgently requested to do so at an early day Having entered upon another year of membership, they are morally and legally responsible to the Association for the payment of their annual dues, having already received for three months of the new year—1885—the Journal of the Association

Subscriptions to the Journal, from those who are not members of the Association, should be forwarded to the office of publication, 65 Randolph Street, Chicago, and not to the Treasurer, but *all payments of annual dues must be forwarded to the Treasurer, Lock Box 1274, Philadelphia*

Deaths —When a member of the Association, who is in regular receipt of the Journal, dies, his family or other representatives are requested to inform the Treasurer at once of the fact

Payment of Dues for Previous Years —As a few members of the Association are still in arrears for payment of dues for 1883 and 1884, they are requested to forward at once to the Treasurer the amounts for which they are indebted to the Association

Transactions of the Association —These annual volumes, thirty-three in number, to 1882 inclusive, may still be obtained, with few exceptions, from the Treasurer, at reduced prices The Index to these volumes will be forwarded on receipt of *One Dollar* An opportunity is thus afforded to complete sets of these valuable publications, or to obtain important papers and works which are daily becoming scarce Yours respectfully,

Richard J Dunglison, M D , *Treasurer*

Sept 25, 1885 Lock Box 1274, Philadelphia, Pa

MISCELLANEOUS

American Academy of Medicine —The next annual meeting of this organization will be held in New York City, commencing on October 28, 1885 Dr A L Gihon, U S N , is President, and Dr Richard J Dunglison, of Philadelphia, Secretary

Died —Dr John L Atlee, of Lancaster, Penn , died at his residence on October 1, 1885, aged a little more than 85 years Dr Atlee was an ex-President of the American Medical Association, an eminent physician and surgeon, whose practice had extended over the unusual period of 65 years He was not only eminent in the profession, but equally so as a citizen in all the relations of human society

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT U S ARMY, FROM OCTOBER 3 1885 TO OCTOBER 9 1885

Capt J H Bartholf, Asst Surgeon, ordered from Ft Ringgold to Ft McIntosh, Tex , for duty as post surgeon (S O 125, Dept Tex , Sept 28, 1885)

Capt Daniel Weise, Asst Surgeon, to be relieved from duty at Camp at Rock Springs, Wyo , and to return to his proper station, Fort Fred Steele, Wyo (S O 99, Dept Platte, Oct 1, 1885)

Capt Victor Biart, Asst Surgeon, sick leave of absence further extended six months, on surgeon's certificate of disability (S O 227, A G O , Oct 3, 1885)

First Lieut G E Bushnell, Asst Surgeon, granted leave of absence for one month (S O 215, Dept East, Oct 6, 1885)

First Lieut Wm Stephenson, Asst Surgeon, relieved from duty at Ft Niobrara, Neb , and ordered for duty at Camp at Rock Springs, Wyo (S O 99, Dept Platte Oct 1, 1885)

First Lieut A R Chapin, Asst Surgeon, leave of absence extended one month (S O 230, A G O , Oct 7, 1885)

OFFICIAL LIST OF CHANGES IN THE MEDICAL CORPS OF THE U S NAVY DURING THE WEEK ENDING OCTOBER 10 1885

Bright, George A , Surgeon, to U S Str "*Brooklyn*"

Fitts, Henry B , Asst Surgeon, to Naval Hospital, New York

Hall, John R , P A Surgeon, detached from Naval Hospital, Mare Island, Cal , and ordered to the "Hartford"

Swan, Robert, P A Surgeon, detached from Naval Hospital, New York, and ordered to the "Brooklyn"

NOTES IN SURGICAL GYNÆCOLOGY[1]

BY HORATIO R BIGELOW, M D
OF WASHINGTON, D C

MINOR GYNÆCOLOGY

I do not desire to embarrass the members of this Section with any labored discussion of literature, statistics, or pathology, but simply to state as briefly as may be such suggestions as observation, study and experience have shown me to be of importance

Sutures—Carbolized silk, mutton-gut, carbolized and hardened in alcohol, whale gut and kangaroo tendon are rapidly assuming prominence The wire suture is dying, and after a long life of usefulness we see simply that *it*, too, must follow the law of the survival of the fittest, and give place to better methods The silver wire suture was not an ideal surgical invention It was ever an irritant, and always necessitated after interference of more or less annoyance In Emmet's operation the gut answers every purpose, and after seeing several operations attended with the best results following upon its use, and that of the continuous stitch, I am strongly in favor of such procedure in every instance This manner of stitching is the rule in similar conditions in other parts of the body, and there seems to be no reason why the cervix should be excluded from the category Mutton-gut is very strong and easily absorbed *Aseptic silk*, in lacerations of the perineum and in gynæcological plastic surgery, generally subserves a most admirable purpose I have witnessed a very large number of these cases, and have assisted in many of them, but I have never seen the wire used during my residence in Germany Silk is used exclusively in perineal operations, and is much more comfortable for the patient *Iodoform collodion* is used to paint over the line of stitching in perineal operations, and is of especial advantage when it becomes impossible to use antiseptic dressings

The Curette—The objections urged against the intelligent use of this instrument lose force in face of statistics If the uterus be first irrigated with carbolized water, then curetted, then injected with tinct iodine or liq ferri, and then again irrigated, there will be no bad results As a diagnostic and therapeutical agent it is highly valuable It accomplishes in one sitting, and with little risk, what nothing else can This also may be said of uterine injections of iodine and liq ferri—when proper precautions are used they should not be followed with colic I have personally seen over one hundred such injections, either with or without curetting, and in no instance was there any bad after result On the contrary the patients were immediately and appreciably relieved Dr Landon has made over 500 injections with only one case of well-marked colic, and has witnessed over 1500 such injections, with one death, at the clinics of Prof Schrœder and Gusserow, and at Dr Martin's Poli klinite such injections and curettings are made daily upon several different women If the curette will not enter, dilate at once with graded dilators, and then curette But do not use the sponge tent for such a purpose, time is lost, nothing is gained, and much risk of septic poisoning is incurred In pathological conditions of the mucous membrane of the uterus, with the alarming train of symptoms so characteristic of endometritis, the hæmorrhage is at once arrested, and the membrane of the uterus, stripped of the little polypoid growths, is allowed to regain its normal condition Irrigation and caustics will have no effect here As to treatment of endometritis diffusa, or fungosa, or glandular hypertrophic, or glandular hyperplastic, or interstitial endometris, the curette is the only thing that will achieve any good result And it does this by reason of the changes it sets up in the uterine mucous membrane

Alexander's Treatment of Prolapsus Uteri—Shortening of the round ligaments for the cure of a prolapsed uterus has not found much favor on the Continent, and failed entirely in the accomplishment of its purpose in the only instance that I knew of in which it was resorted to in Germany It might possibly be of some avail in backward displacements of the uterus, but I cannot see how it can be of any service in prolapsus, even though the uterus may depend, as Dr Alexander claims, upon the resiliency of the surrounding tissues for its support This theory is hardly tenable in view of the pathological and physiological processes in both the bladder and intestines, which necessitate a constant change in the amount and direction of the pressure upon the uterus, so that the support is at no time the same, and at some period may be absent altogether Yet all this may and does happen without a consequent prolapsus uteri

ABDOMINAL SURGERY

I still continue my firm belief in and adherence to strict antiseptic detail I regard such precautions as a *sine qua non* of success Were means and opportunity to come into harmonious conjunction, my procedure in all laparotomies would be somewhat as follows A well lighted, well warmed room, with sanded walls and stone floor, in which the spray had been playing for some hours previous to the operation, a set of instruments used only for abdominal surgery, porcelain basins, no sponges, all the water used to be previously boiled, the spray to be in action during the entire operation, two assistants (one having charge of the anæsthetic and the other being opposite the operator), and one or two good nurses, to handle the basins, instruments, etc The patient should have a carbolized bath the night before the operation, and the hair should be shaved from the pubes An operating table of galvanized iron, made in sections, the section under the lumbar region of the patient being so arranged that it can be dropped down, so that the bandages can be passed around the body without disturbing the patient (Martin's table) It can be made so low that the operator can sit between the patient's legs, and thus be very comfortable, or high enough for him to stand at the left side The temperature of the room during the operation I would have at 80°–82° F The abdomen of the woman should be well washed with soap and water while she is being anæsthetised, and then rubbed off with mercuric bichloride solution 1-2500 or 1-3000 Flannel wrung out of hot water, or hot bottles should be under the arms and along the body, the extremities and trunk being thoroughly protected with flannel All instruments and ligatures should be kept in carbolized water, and all the assistants should be *aseptic* in the strictest sense of the word A few visitors only could be allowed, and it should be equally necessary for them to be aseptic The door should not be opened after the operation had begun All cysts should be evacuated with a trocar, because it is more cleanly than the simple puncture, which allows the contents to dribble over the patient The cavity being exposed, I would protect it from contamination by cloths wrung out of hot water (antiseptic) These keep the bowels in place, and can be packed nicely around the stump, or else I might use Marcy's rubber sheet, which completes most satisfactorily the toilet of the peritoneum

---

[1] Read in the Section on Obstetrics and Gynæcology at the Thirty Sixth Annual Meeting of the American Medical Association

Sepsis is of course the hydra-headed monster against which the operator is called upon to exercise most zealous guard and watch I become more and more impressed also with the belief that a sudden reduction of temperature may exercise a most pernicious influence, although that opinion is not shared be gynæcologists in Berlin I cannot believe that a large mass may be removed from the abdomen without withdrawing a certain amount of heat developed by its presence, and I cannot believe that the central nervous system will not appreciate the difference It is for this reason that I would anticipate the change by supplying external heat to the patient This being provided for, every energy is directed toward the prevention of sepsis Until some better measure be devised, or until the opponents of antiseptics shall be able to show that the present scrupulousness of German operators is without any foundation as a scientific process, I shall continue to believe in its great name Nay, more I shall believe that the greatest measure of success will be his who exercises the most rigid antiseptic precautions The stump, in simple cases, may be sewed through and through with the cobbler's stitch, or several interrupted stitches of double thread, passed through the substance at short distances, may be used, or the the pedicle may be tied in halves and dropped The pedicle can also be tied in halves, and the flaps above the stitching may be brought over and sewn together above the first, so as to give a double protection I have already had my say in regard to the intra-peritoneal treatment of the pedicle, and expressed my preference therefor As yet I have seen no reason why I should change It is an easier operation, it does not require so much time as the extra-peritoneal method, it is much neater, and to my mind a much better surgical procedure Formerly there was a question of hæmorrhage Now-a days, this is a factor of small importance, since experience and intelligent advance has taught us how to control it The elastic ligature was a happy device, and with it one can operate safely and without fear

Shock—rather a vague and uncertain term, has grown to be synonymous with want of facility in the operator, by which the operation has been unduly prolonged, provided always that the temperature of the body has been kept up to a proper standard—for I fancy that in former days many cases of so called shock may have been deaths from a lowering of the temperature

By the intra peritoneal method drainage of the whole peritoneal cavity may not be possible, and of course the incubus of sepsis will hover around like a black cloud for several days In view of this, Dr Martin's article on the treatment of the stump after myomotomy (*Berl klin Wochenschr* , 1885, No 3), will be read with much interest In certain cases, especially those in which he thinks that the absorbent power of the peritoneum may be interfered with, he makes use of prophylactic drainage Without this drainage he had thirty-one cases, with a mortality of 35 5 per cent , with drainage he had twenty-nine cases, with a mortality of 24 2 per cent To this he adds five cases of supra vaginal amputation of the uterus, one being treated without drainage and four with drainage, making thirty-two cases without drainage, the mortality being 34 per cent ,—of which 21 9 per cent were from *sepsis* Thirty-three cases were treated with drainage, with a mortality of 24 per cent , of which 12 per cent died from *sepsis* After gastro-hysterectomies he drains from Douglas's cul de-sac through the vagina The treatment of the stump in the intra-peritoneal gastro-hysterectomies is a matter of importance and interest It seems to me that this is best done by utilizing the peritoneum as a flap, as described by Martin in his book on the Pathology and Treatment of the Diseases of Women, and by making sure, before returning the stump, that there is no oozing These two questions—the arrangement of the stump and prophylactic drainage—ought to be provocative of discussion, since they go to make up the sum and substance of this plan of treatment. Hofmeier's recently published monograph on Prof. Schrœder's 100 laparotomies (the number now is considerably more than that), may be studied with advantage.

Extirpation of the Cancerous Uterus through the Vagina.—Operating after his own plan, I have seen Dr. Martin make this extirpation in forty minutes without losing any blood—or at least without losing but very little. The operation is, however, a difficult one, and would be impossible in a constricted vagina, or if the uterus were very much enlarged. It is not easy to get the finger up through the posterior opening at the vaginal insertion, and unite the ligamentum lata with the peritoneum and vaginal wall, and even in the first stitches which unite the peritoneum with the posterior vaginal arch, the operator may fail, as others have done, to include the peritoneum. It is well to cut with one sweep of the scalpel directly into the cul-de-sac of Douglas, and then unite these cut surfaces—peritoneum and vagina—before going any further. The stitches must be drawn as *tightly as possible*, and Dr. Martin is in the habit of using about four of them. A double thread is used with the lig. lata, and the needle should come out about one ctm. from where it went in. This requires nice manipulation, and the index finger must be delicate in its sense of touch. The great merit of this operation is that it is rapidly done, and with the loss of the smallest possible amount of blood.

After-Treatment.—In plastic operations upon the vagina or upon the cervix, if aseptic silk be used, there is no necessity for further interference. In lacerations of the perineum, the stitches can be removed in a week. The vagina can be packed with iodoform gauze (gauze well soaked in iodoform and glycerine), the parts having been powdered with iodoform immediately after the operation. When changing the dressings, it is a good plan to irrigate thoroughly with carbolized water. When the vagina is not tamponed, warm antiseptic injections should be kept up daily. This should be carefully done, so that the nozzle of the syringe will not irritate the cervix, and the reservoir and receiver should be so arranged that the woman can lie in bed with the hips elevated, and allow the injection to go on for half an hour at a time. After amputations of the cervix, there is often a good deal of posterior inflammation, which resists treatment for a long time and is wearing upon the patient. This yields in time to *patience* and *hot water* injections. The bowels must be kept soluble. Constipation, a prevalent complaint among women, keeps up the inflammation, and each passage is attended with severe pain. After laparotomies, careful nursing and judicious feeding are of primary importance. Morphia should be given at first as occasion may require, and the bladder should be emptied by the nurse until the woman can safely do so herself. When indicated, an ice-bladder over the abdomen is frequently called into requisition in Germany. For the first few days, milk, wine and water and bouillon may be given—but nothing should be forced upon the patient for some hours after the operation. Mellin's Food subserves a useful purpose, as it furnishes *heat*, and can be retained by the most delicate stomach. From the fourth to the seventh day, a little meat may be added. The drainage tube may be removed upon the third or fourth day. All dressings should be renewed under the fullest antiseptic precautions.

Abdominal surgery has not as yet risen to the importance of a *distinct* branch in Germany. Professors Gusserow and Schrœder are professors of both obstetrics and gynecology, and perform all the operations coming under both heads. With proper precautions, I cannot see why a man who makes an "Emmet," or an amputation of the cervix, or who delivers a woman, should not also do a laparotomy. If he change his clothing and take a bath, as every one must do who attends a laparotomy in Berlin, and if he has a distinct set of instruments for his abdominal work, there can be little danger arising from his having come from a case of labor. Schrœder and Martin have done splendid work, and yet they are busy at all hours of the day in the various departments of obstetrics and gynecology. Besides a perfect technique, they are both firm believers in antisepsis. Gusserow in diagnosis and pathology, Schrœder as a didactic lecturer, and Martin as an operator form a notable triumvirate.

THE RELATION OF MIND TO MATTER[1]

BY AMOS SAWYER, M.D.,

OF HILLSBORO, ILL.

It is an evident fact that the materialistic theory is at the present day, among educated people, the popular one, but when, if it has not already reached its flow, the ebb sets in, it will be discovered that the members of the medical profession have in no small degree been responsible for its dissemination, as their preparatory studies necessitate the investigation of matter and its properties, and in the pursuit of this knowledge they lose sight of the fact that there is something immaterial in man, and that some of his acts are free. The same cause exists in all the branches of science, producing like effects, consequently scientific men are largely in the majority in the materialistic ranks, with the medical profession well represented, and all this in the face of the fact that every practitioner of medicine admits, that in numerous instances he recognizes the necessity for the treatment of the mind (whatever he may mean by the word) more than the body. Schiller said: "I abandoned surgery for philosophy and poetry because I found the wounds of the spirit were so much graver and more numerous than those of the flesh." The confidence with which the patient turns with almost every thought to his physician places him in a position next to God, and therefore the expression of an opinion carries with it a weight second to none, hence the relation is a responsible one.

The object, therefore, I have in view, is to attempt to prove that freedom of volition does exist, and that it is incompatible with matter, that man's actions prove that he is not all matter, for in some of them he chooses, and therefore is free, and that the molecules of matter remain as they were created, unbroken and unworn. If I fail to make clear the position I have assumed, if my reasoning is defective, yet should it only awake in the mind of one of my hearers a train of thought that will enable *him* to clear away the cloud which prevents so many from distinguishing the material from the immaterial, the mind as something distinct from matter, though so intimately connected with it, I shall feel amply rewarded for my efforts.

---

[1] Read before the Mississippi Valley Medical Society, Sept. 9, 1885.

Mind and matter are the two factors of the universe. *Mind produces, matter is the product.* And here, perhaps, it will be proper to explain what I mean when I make use of the terms, matter, a simple being, and a spiritual being. Matter has weight, and occupies space to the exclusion of other matter. It exists in three forms, solid, liquid and gaseous, and may be simple or compound. A simple being is not matter, but dependent upon matter, and therefore is material, as light, heat and electricity—forces in a body. A spiritual being is independent of, though incased in matter, and has an extrinsic dependency on matter because it depends upon the nervous system for the report of sensations, and depends upon the body for its compound life with the body, and God does not create it except in a body. Such an entity is *spiritual*, is *immaterial*. The light and heat of the sun is represented when wood or coal is consumed, and the force thus generated is that conserved in their formation, and clearly demonstrates that matter is dominated by a *simple being* (force)—it is the spirit of an otherwise motionless mass.

The materialist declares that there is nothing immaterial in man, that all our acts are necessitated and fated, in other words, we do only what we are obliged to do. What, then, is that mysterious life or entity created only in a body, and which manifests itself in memory, gratitude, love, hate, pride, and the belief in a life beyond the grave, if not something immaterial—spiritual? That we are free we know, for it is a fact of consciousness, human accountability rests on this truth, all laws are based upon it, from those governing the savage tribes, to those of the most civilized nations, for there can be neither reward or punishment, vice or virtue, where there is no freedom of action. Convince a jury that a man's actions are not free, and conviction is impossible. But apart from this, and that inward spiritual speech which alone greets that marvel of creative love—man—and which prompts him to do good and shun evil, and out of the wreck of every earthly hope bids him trust in that unseen creative power for rest in the realms above, there is other evidence inexplicable save by the admission of something not matter controlling our actions. Localized cerebration has been advanced by the materialists as an unanswerable argument in favor of their theory, the seat of intelligence being in the anterior and posterior convolutions of the cerebrum, and that memory has been located in the fissure of Sylvius, near the island of Reil, but is it memory? No! it is merely that portion of the brain where the mind receives, communicates, and expresses the recollections and opinions of subjects and objects, in other words, by certain nervous combinations it reproduces at this spot impressions received. But if I am wrong, and memory is merely the substance of the brain, how is it that in old age, when since youth the grey and white matter have been frequently renewed, we can retain the memory of childhood years? Is it written there as upon parchment? What a mental cyclone there must have been among the atoms of grey matter, if Spencer's theory is correct, and fearfully dangerous commotion in the necessarily rapid movements of mind cells according to Hæckel's idea of cerebration, when Mithridates, king of Pontus, was calling each of his 80,000 soldiers by name! Scipio knew all the inhabitants of Rome, George III never forgot a face that he had once seen, or a name that he had once heard, when Lord Granville could repeat from beginning to end the New Testament in the original Greek, Bossuet could repeat the whole Bible, all of Horace, Virgil, Homer, and many other works. These are a few instances only of remarkable memories, or immense cerebral storage capacity. Can the substance of the brain store a lifetime's experience, and reproduce it at will? But stop! *The will of what?* It must be something superior to, as it controls matter. When we read something ludicrous, the mere sight or sound of the words (actions of matter) do not cause us to laugh, but it is the *ideational* change developed in something apart from matter which affects the risibilities, for if this act was merely mechanical, then every normal cerebral mass subjected to the same sight or sound (cause) should induce the same effect (consequence), but the fact that it does not, but frequently the opposite, excludes such a hypothesis. The same can be said of all our emotions. Why is it that we may become so accustomed to the striking of a clock as to become unconscious of its presence, if the impressions are made only on matter? For the vibrations of the air were transmitted to the delicate membrane of the ear as usual, and from thence to the brain by the natural mechanical and neurotic process, not a sound escapes it, consequently, if *matter* alone takes cognizance of sound, then, as it did make an impression on the substance of the brain, it should have recognized the number when it struck the hour, but the fact that it did not, proves that the cognition or intelligence *is not composed of matter*, but is distinct from it.

I am aware that some materialists claim that the recollection of past events is merely setting in motion again the molecules of grey matter, or, as Hæckel expresses it (Vol. 1, pp. 127), "the mind cells which possess the capacity to feel, to act, to think," which originally produced the perception. (Query—What is *that* capacity? Evidently it is something superior to and distinct from the cell it controls.) But if this be true, I ask, what controls, and what sets these cells in motion again? For that we possess this power, every intelligent person must be conscious, the loss of it *is insanity to that degree*. Why is it that two persons, after viewing a subject or object, arrive at different conclusions? or why, by evidence or reasoning, change them, if the impressions made are simply movements or arrangements of the mind-cells, or impressions on the grey substance of the brain? What has the power to effect the rearrangement of brain substance, and adjust the cells so as to form the new impression? Surely this is only another name for that intelligence which we call spiritual. If not, then the darkness is simply intensified by this kind of an explanation. It is strange how differently the cells arrange themselves, after viewing the same subject or object, in an educated and ignorant person, or even in two persons of equal mental calibre. The school boy is not blameable when he has imperfect lessons, it is merely the wrong arrangement of the mind cells, or the loss of "force" to call up the right ones, though the effect produced upon them by corporal punishment is wonderful, for after a thorough administration of this remedy, we usually find them better prepared at the next recitation. We may be in doubt which of two ways is the correct one to spell a word, but by writing it we can, from the appearance, quickly decide which is right. Now, as there must have been in this case two different arrangements of mind-cells formed in the brain if this theory is correct, what was it that decided the question? We may recall some passage or verse committed to memory years ago, and although we can repeat it word for word, a doubt often arises as to its correctness which can only be removed by reference to the original. Now, what caused this feeling of doubt? It could not have been the mind cells, for they were arranged right, and if they *think*, they must have known it. Why do we then, if this theory be true, condemn defaulters, murderers, thieves, etc.? It is merely the wrong arrangements of the mind cells which impelled them to commit the act, though most of them will admit, that had they heeded that "monitory voice"—that force or capacity—that *something not matter*, which warns us as we walk, and rebukes us when we stray, they would not have fallen. No, we do not inflict punishment upon *machines*, as this theory makes us out to be, but upon *hearts*, *souls*, *characters*, when they have been false to their Creator, to their fellow men, and to themselves by the violation of the law which the natural exercise of their *free will* would have prevented.

Dr. Zuckertort, the chess player, says, in explaining how he is able to play several games at the same time without seeing the board. "I have a way of photographing a board in my mind, and the boards being numbered, when one board is called, the photograph of the position of the men on the board comes instantly before my mind, while the last board disappears, I never see two boards before me for a single instant." Now, what is the power controlling that "force" by which this mind cell shuttle is moved back and forth to the fissure of Sylvius in its proper time and place, if not something superior to, and apart from matter? For, if force acted alone upon matter, the boards would reappear in the *inverse* order of their formation, six, five, four, etc., but the fact that they come as called, one, and five, and three, and six, is *conclusive evidence* that the simple being (force) is controlled by an intelligent, creative power superior to it, which we call mind (a spiritual being). The truth is, that in their attempt to explain these and kindred phenomena, the materialists are led to attribute to laws and actions of matter, what in reality are actions and laws of spirit.

That successful physicians, generals, merchant princes, and landed aristocrats must possess similar powers to those evidenced by Dr. Zuckertort in the game of chess, there can be no doubt, but if this phenomenon is due *alone* to the action of matter, then, as the quantity and quality of brain substance used in cerebration in these cases must be about the same, they should be able to change position with each other with equal success, just as a car constructed to carry ten tons of freight, will transport with equal ease and safety that weight of corn, coal, or any other substance, but that this is not the case with the brain we have convincing proof in the numerous individual instances we can all recall. This demonstrates that its movements are controlled by a spiritual being (mind) acting through a material substance, and that it is not matter that chooses what is agreeable and suitable for its development, for when this spiritual desire is disregarded, failure inevitably follows. If the brain be perfect in quantity, quality and construction, the psychical endosmosis and exosmosis emanating through such an instrument, with proper advantages, will place the possessor among the conceptive and accomplished of his day. Webster's brain would not have varied a single iota in weight or appearance had he remained an ignorant country farmer, but had that something not matter (mind) which marks out the path for, and urges us to follow through life, prompted him to become a chemist, an astronomer or a geologist, there is little doubt but that he would have become as renowned in that branch of science, as he did as a jurist and a statesman. We would not expect a man to make lumber with a hand saw, or think of blaming the engineer because he could not make his engine draw 300 tons when its traction power was only 150. It is exactly so with the mind in its relation to the brain.

The materialists assert, in proof of their theory, that we have no cognitions except such as are afforded us by our sensations, but that we cannot rely on our sensations because the object may not be as our sensations perceive it to be. What, then, do we know? Only that we are and that we feel something, hence we can never know what we are or what we feel. That this reasoning is false we must all acknowledge. To illustrate, if marble, or substances possessing similar properties, be brought in contact with the skin, the impression conveyed to the senses and the sensational understanding is that they must be colder than other substances, such as wood, etc., and this impression would remain, was there not a power apart from and controlling matter, which, regardless of the sensation, informs us that the coldness is illusive, and due to its greater capacity for the absorption of heat, in other words, it is a better conductor. Again, it is evidenced in traumatic pressure of the brain, for we find, after a long interval of insensibility, the mind *at once* resumes its function when the obstruction which prevented the machine (brain) from working is removed. Some twenty-five years ago, Dr. Brainard, of Chicago, removed a piece of depressed bone from the head of a sailor who, twelve months previously, had fallen from the rigging of a schooner and remained insensible up to that time. The moment the pressure was removed, the mind gave proof of its readiness for action by recalling the event, although the past year was a blank in his life. Another case, still more remarkable, occurred in Maine. The son of a miller, while standing on one side of the mill-pond, at a banter from his father, who was on the other side, shot at a snipe standing on a rock in the middle of the pond, the ball missed the bird and, glancing from the stone, struck the father in the forehead. He remained in an insensible condition for nearly two years, when a depressed piece of bone was removed, and the mind taking up the thread where it had been so suddenly broken, he exclaimed: "Zeck, you dog, you missed it," thus proving that in the almost imperceptible interval between the shot and the reception of the injury, the mind had mirrored the fact that the bird was unhurt, and had framed an answer for delivery. Force *alone* could act so instantaneously, but neither force or matter, alone or combined, could retain the knowledge of the event for such a length of time.

If I call a materialist's attention to my watch, and in explanation inform him that in strength in construction, beauty in design, and regularity of movement the jewelled time recorder approximated so closely to perfection that, regardless of thermometric, barometric and electrical changes, the variation would be but the fraction of a second in six months, he would then naturally enough ask: Who made that watch? If I should reply, "No one made it, it made itself," would not this answer justly enough elicit the interrogation, "Is he an idiot, or insane?" The eighty-one stars in Orion have moved back and forth for thousands and thousands of years without collision or departure, for they move with a regularity and precision of which the description of the watch forms but a beggarly illustration. This infinite, endless motion of the stars, this magnificently majestic illuminated planetary procession, moving with a precision which enables us to foretell for years in advance where their shadows will fall, instinctively and intuitively, prompts the question, Who made them? If I reply "They had no maker, *they made themselves*," then, instead of pronouncing the sentence, "He is a *fool, or lunatic*," the materialist exclaims, "Behold an advanced scientist and philosopher!"

I ask the materialist how he accounts for the phenomenon of cerebration? Herbert Spencer answers, 'The mind exists wherever gray matter is found, whether in the axis cylinder of Purkinje, or the neoplasm of the cell itself, and whether found in the tentacle of the cuttle fish, the tail of a dog, or the brain of a man." Hæckel assures us that "the mind is composed of cells which possess the 'capacity' to will, to act, to think," but here we find that they are acted on by some superior force controlling them, and are therefore merely instruments, for if I ask, What do you mean by the word capacity? they answer, "We mean force." Now what is this peculiar force (something created only in a body), not possessed by other cells? That you believe or are convinced of the truth of your assertion I have no doubt, but this will not answer the purpose, how do you *know*, how can we become *conscious* that volition is due to the action of peculiar brain cells, gray matter, or any other substance peculiar to the cerebral mass? Surely it cannot be accounted for in the composition of the material out of which they are constructed, certainly the different form of the cell will not explain it, therefore it remains a very pretty undemonstrable theory without any foundation of facts. That Hæckel was honest in his *belief* that he had discovered that the mind consists of peculiar shaped cells, and that Spencer *thought* that he had demonstrated that the mind was simply the gray matter wherever found, I would not question, for with their conception of it (as we are seldom more than we deem ourselves to be), they would naturally enough expect to find it as quickly in the tentacles of the cuttle fish, or a dog's tail, as in the brain of a man, though Spencer has never shown, nor have we any data that would warrant us in asserting, that a bob tailed dog possessed less intelligence than before he was curtailed of so much of his mental faculties. With the evidence adduced such a predicate would suggest that in his search to discover the origin of this mysterious force, he had exhausted his brain and arrived at this conclusion through an act of cerebration at the other end.

If you ask me, What is the mind? I would answer: That something created within us that can be used to control the voluntary actions of man, as evidenced in his ability to do good or evil, to seek that which is pleasurable and avoid what is painful, to choose the occupation best suited to his endowments, the recollection of names and the objects to which they belong, that which appreciates the character of the impressions received, which knowledge enables us to adopt means for the accomplishment of particular ends, that which forms conceptive ideas in the brain of man by which he moulds the other factor (matter) into forms which, but for this, would not exist, as works of art, and the inventions so necessary for success in peace or war, as well as in the struggle of civilization against barbarism. There is *no other source* whence they can come. In a word, every successful invention is an idea realized—it is the *material* construction of a *mental* conception, and which, but for this, would never have existed, it is this *preexisting* form in the mind that guides the artist's and the artisan's hands, that made an Archimedes and an Angelo, and just as this psychical model is perfect or imperfect, distinctly or indistinctly seen, will the material form shadow forth more plainly than can be told in language. It is related of Michael Angelo that in explaining to a visitor at his studio what he had been doing at a statue since his previous visit, he said: "I have retouched this part, polished that, softened this feature, brought out that muscle, given some expression to this lip, and more energy to that limb." "But those are trifles," remarked the visitor. "It may be so," the artist replied, "but trifles make perfection, and perfection is no *trifle*."

It is the mind that rules. It is this same factor which enables us to look into the future as well as the past, and profit by the experience of those who have preceded us.

Now gray matter, or a so called mind cell, no matter what form it may assume, by which it is distinguished from other brain cells cannot distinguish the phenomenon except as an *instrument*, because it is composed of matter, and matter can act only as it is acted on. The brain and nervous substance are similar in their chemical nature. The chief difference between the white and gray portion is in their structure, the former being composed of nerve fibres alone, the latter containing, in addition to the nerve-fibres, interstitial matter and nerve cells. They contain eighty per cent of water, the solid matter consisting in part of a protein body, in part of a body which, by the action of acids, yields products similar to the viscous matter of the yolk of an egg, a fatty crystalline acid which contains nitrogen and about one per cent of phosphorus, named cerebric acid. Cholesterine is also present, and an oily, fatty acid containing phosphoric and oleic acid. Now what is there, singly or combined, in these substances which could possess the power "to will, to act, to think?" That they are composed of matter is proved by the fact that they can act only as they are acted on. For you may mix them all in the proper proportion, yet you cannot form organized brain substance, but were it possible to accomplish this feat, can we think for a moment that it could be made to perform the act of cerebration? No, for it would lack the presence of that capacity, that force, that something *not matter*, which vitalizes and controls it. Just as a stream of oxygen and hydrogen gas, though they have a strong affinity for each other, may be mingled with impunity, but the mere presence of a piece of platinum sponge will cause them to combine, though the platinum is not changed in the slightest degree. This something encased in matter is the platinum for our body, and so long as it remains and the chemical elements are supplied, just so long does it perform its katalytic office, and the force thus generated acts as the motor for our various vital processes. It is true, that under certain circumstances we can take the human machine after the katalytic, entity has taken its flight, and by inducing artificial respiration molecular life will remain for a limited time, but this result is obtained by the exercise of an external, as before it was due to an internal, force, both genererated, however, in the same way. But that something, created for it, that we call life, can never be recalled, the somatic death removed, or the once intelligent being be made to respond in this world to inquiries. In volition, if it be regarded as the effect of chemical action, the same quantity produces results as different as the school girl's musical composition and the masterpiece of a Mozart, a Raphael's conception of the Madonna and the daub of a sign painter. No quantity or quality of brain matter ever generates a true idea, or a false one. Matter does not think, it does not feel, and how an impression upon the periphery of a nerve becomes transformed into a *sensation* is, as Professor Huxley remarks, utterly unknown to us, and still more obscure is the character of self-conscious intellection.

Finally, as materialism is the study of matter and its properties, it is essential for a materialist to be a chemist as well as a physiologist, in order to investigate the subject intelligently, yet how few of the members of this school possess these necessary requirements? Chemistry informs us that everything in nature, whether simple or compound, depends for what it is, upon that which is not. It shows us, among a host of other things, that C_4H_8O, with the atoms grouped differently, produces the disagreeable smell of rancid butter and the agreeable odor of ripe apples, $C_8H_5O_6$, for like reasons, forms the different bodies, sugar, starch, and wood, but the force that grouped them remains an unknown factor. It answers the question, What is the quantity, quality, arrangement and the mechanism of the atoms which give form to animals and plants from conception to maturity and death? but it is utterly unable to explain why, what or whence came that mysterious microscopic atom of energy, the presence of which gave birth alike to the giant oak, the modest blade of grass, the huge mastodon and the infinitisimal infusoria. It speaks to us of design in language not to be misunderstood, when it shows that every organic and inorganic substance is composed of an undeviating combination of atoms held together by a force not inherent in any one or the combination, for if we reduce an organic substance to its ultimate atoms, collect the oxygen, hydrogen, carbon, nitrogen, etc., we are incapable of putting them together again because we cannot generate the life force which originated it. Chemistry tells us the composition of common salt, but it cannot explain why this healthful compound is formed by the union of two deadly poisons. The physiologist has located memory and the receptive points in the brain of man and that stimulus which induces many of his volitional acts, but what it is that retains and reproduces—that wills—it cannot solve. Physiology furnishes the proof that growth and decay, waste and repair, are simply the chemical processes of secretion and excretion, or an endosmotic and exosmotic action, but how the atoms should be so grouped as to form a microscopic thread of matter containing all the necessary foundation stones upon which to build a little image of the animal within whom it was deposited, with all its varied and intricate organs, is a physiological enigma, nor have we any data for speculating as to its origin. It has demonstrated that the function of the nervous system is to associate the different parts of the body, and it informed us as to the interval of time between the application of stimulus to one organ and the excitation of activity in another, but it is arrested when it attempts to explain what it is that appreciates the character of the impressions received.

Therefore we reason, if the faculties of memory, gratitude, love, hate and pride, the power of self-control, of looking into the future as well as the past, of reasoning from cause to effect, is simply the effect of chemical combinations, then the same physiological properties of the hemispheres of the brain in man should be reproduced in the lower animals, as well as in all organic substances where this same process is constantly at work, and upon which their growth and existence depends But the absurdity of such reasoning is shown when we see that, although the chemist has determined, with the utmost accuracy, of what elements the proximate constituents of plants are composed, and by what proportions by weight, he has never yet succeeded in reconstructing these constituents from their elements We cannot imitate, by art, the workings of nature in living plants as we can do most perfectly in inorganic chemistry Certain it is that if the act of volition is due to molecular life, then as this does not cease at the moment of death, but can be maintained for a limited time thereafter, then while the cause remains the same effect should manifest itself, but the fact that with somatic death they cease, proves that it is not consequent on or dependent upon chemical change, but is distinct from it, in other words, it is dependent upon some departed superior force or cause Thus we have traveled over a scientific path to say what the mind is not, what it is in its essence, will ever remain, in this world, a mystery We also see that the materialist is encompassed with fears and doubts unknown to the Christian, and if, as Hæckel claims, "the theory of the creation is a blind belief," how much more so is that of materialism, "the scientific theory of evolution," in the former we follow a bright ray of light, while the latter is impenetrable darkness

In conclusion, then, we know that the organic portion of all living organisms is formed by chemical combinations, induced by a katalytic something, and governed by certain immutable laws by which the atoms of matter are so arranged as to give the distinctive form and size in accordance with the microscopic foundation of the sperm model deposited in its proper creative receptacle We know that chemical combinations do not, nor can they be made to, give origin to life in any of its phases, and, therefore, in accordance with an axiom in reasoning, we conclude that this must *always* have been the case, and as matter cannot bestow upon its combinations that which it does not possess, that organic life must be consequent on and dependent upon that which gave it birth—something not matter, hence the materialist should change his name as well as his field, for he must exclude matter in his search for psychical properties and action

We must all admit that the celebrated atheist and scientist, Du Bois-Reymond, was right when he said "With regard to the enigma of the physical world, the investigator of nature has long been wont to utter his 'Ignoramus' (we know not) with manly resignation As regards the enigma of what matter and force are, and how they are to be conceived, he must resign himself once for all to the far more difficult confession—'Ignorabimus' (we shall never know)" We may not be able to give at once an intelligent explanation of all the physical phenomena coming under observation, but we have reason to believe that in the future, as in the past, a solution will be found

ADDRESS IN MEDICINE DELIVERED BEFORE THE NEBRASKA STATE MEDICAL SOCIETY, MAY, 1885

BY ALFRED SHIPMAN, M D,

OF PLATTSMOUTH NEB

The successful treatment of the various diseases which afflict mankind is based upon sound conception of pathology, while pathology has for its basis an absolutely correct knowledge of physiology In the formation of pathology, physiology is indispensable In order to reach a correct diagnosis we must have a correct system of pathology Were the physiological conditions and principles always clearly known and understood, our system of pathology might approach perfection, but physiology is not an exact science, perhaps never will be Absolute knowledge in regard to all and every physiological state and condition may never be attained Physiology may be said to be one of the least mature, because one of the most complex of the sciences Therefore our pathology may remain defective, and if so, the practice of medicine will continue to be an imperfect art, medicine will continue to be a progressive but not an exact science

I am one who believes that medicine is a progressive science, and that in many of its departments it already approaches a precision scarcely realized by many practitioners Contrasting the difference in the practice of to day with the practice current even twenty-five years ago, and who will say no advance has been attained Reduce the time to a review of the progress made during the past society year, and even during this short period the accumulation of material for consideration covers such a vast field of thought that to properly present the same for your consideration in the short space of time allotted to us becomes an impossibility I am free to say that there is a fashion among many of regarding change of any kind, progress A simple change in the manner of treating a particular disease is not always evidence of medical progress We sometimes follow false lights, but not for any great length of time

Actual improvements, and progress in medical practice are the result of careful research Patient investigation, careful physiological research, and abundant experimentation furnish the ground work for all forms of advancement in our art The over confident assertion of one man may prove nothing, but the conjoined experience of many physicians may establish a principle in practice From that day when the fathers in medicine began to record their experience and relate their plans of treatment, down to this, our day, medicine has been progressive Although it may not take the recorded experience of thousands to establish a period in practice, yet it is necessary for each individual member of the profession to give voice to his convictions in order that what little knowledge he may have gleaned may become useful to the profession at large

It is the duty of every physician to patiently, persistently, and scientifically investigate those diseases he is called upon to treat In no other way can he become a competent practitioner, and in no other way can he so well promote the best interests of his patients, himself, and the profession. Actual progress in medicine is necessarily slow. All the numerous theories advanced must be patiently investigated. Investigation must be made in more than one direction. After discovering the etiology of disease, we must master its therapeutics. Theories may be worked out in the pathological laboratory, but these theories must be proven by clinical demonstrations before they can be accepted by intelligent physicians.

During the past few years investigations in the department of etiology have been interesting and very instructive, but perhaps not as profitable as they might have been had more attention been given to clinical observations. It has been said, and the statement still holds good, "that the place to study disease intelligently is at the bedside." Persistent investigation in the biology of germs has certainly yielded some important results, and leading members of the profession now admit that micro-organisms are the exciting cause of numerous diseases. It is quite generally admitted that diphtheria, scarlatina, rubeola, and tuberculosis are germ diseases, while Koch's comma bacillus presents admirable claims for recognition as the one and only factor in the production of Asiatic cholera.

The investigations of Koch in relation to cholera have thrown light in dark places, and it is thought that he has established some facts. He asserts, and has apparently proven, that a certain parasite is present in all cases of true cholera. Specimens of his cholera bacillus have been exhibited to several local medical societies, and converts to his ætiological views are numerous and influential. Investigations conducted by Pasteur, Koch, Cohn, Klebs, Wood, Formad, and others have been conducted principally with the view of proving or disproving the presence of micro-organisms in certain diseases, and the revelations of the microscope have added much to our knowledge of the apparent cause of many individual diseases.

The uniformity with which certain parasites are found in connection with certain pathological conditions clearly establishes the fact that these germs are either the exciting cause of the disease existing, or else are a product of diseased action.

It may be said that the profession is divided in opinion regarding the influence of germs in producing diseases. But it is a fact that a great number, a vast majority, are favorable to the view that the multiplication of infinitesimal parasites is the cause of nearly all the so-called zymotic diseases. The idea that a specific poison may be a living organism is certainly in accordance with common sense at least. It will be of little value, however, for our microscopists to hunt up these parasites, unless we can have more accurate more definite clinical observations, and thereby acquire more positive knowledge as to their pathogenetic value. It may be said that although the theory of Koch in regard to the cause of Asiatic cholera, has received the endorsement of many leading men in the profession, we should understand that further investigation is necessary before we can declare that the comma bacillus is the sole cause of cholera.

Some doubt is thrown around the assertion of Koch and others from the fact that no clinical proof is forthcoming. Although the comma bacillus has been inhaled, swallowed, and injected it is said not a single case of cholera has been produced; probably, we should remember, because the pathological state or condition upon which development of the disease to a certain extent depends was not present in those upon whom experiments were made. The production of a single case of cholera from the immediate introduction of the comma bacillus, would do more to establish Koch's claims than would the assertions of ten thousand men unsupported by clinical proof.

In medicine we do need more facts and less theory. We also need more exact observations of clinical and therapeutical facts. The rank and file of the profession should not be dazzled or confused by the brilliancy appearing in the investigations of a Pasteur or a Koch; it should not accept, without question, their opinions in regard to any supposed discovery which is unsupported by any clinical proof. It appears to me that humbler members of the profession are losing interest in clinical observation, and delegating investigations entirely to that enterprising branch of the profession represented by the microscopist. We cannot investigate disease intelligently with the microscope alone; it is true that this instrument has given us much valuable information, but the time has not yet arrived when we can diagnosticate disease by it alone. The profession should not lose sight of the examples of clinical work given us by Trousseau, Watson, Flint, Roberts, Da Costa, and other safe guides in medicine. Neither should any of us abandon our efforts to solve the problem of diseased action by close and accurate observation at the bedside. The needs of more accurate bedside investigation of disease was never more apparent than it is to-day.

The promulgation of what we call the germ theory of disease needs closer investigation, not only further microscopic test, but more careful experimentation. Undoubtedly we are on the eve of an important epoch in medical advancement. Especially is this the case in regard to a class of diseases which the profession have long regarded as being caused by some special infection. Is there a special infinitesimal parasite, one kind of which originates cholera, another diphtheria, and so on? Is there a particular organism for each one of the zymotic diseases, or are these germs simply one of the morbid elements in the pathological condition present?

It would add much to the credit of our profession, if this perplexing question of the part that micro-organisms play in the production of disease could be settled at once. But it is not given to man to know all things, and it is probably a fact that the more deeply we enter into the invisible constitution of matter, the more confusing the problem will become. For example, it is impossible to recognize some of these micro-organisms with our highest magnifying power, unless they are first passed through a staining process. The manipulation necessary in the hunt after these germs certainly requires the exercise of great, or exceptional skill, and the possibility of error is present in every examination. Nevertheless, although a positive indisputable demonstration in regard to germ influence may be impossible at this time, there may, happily, be further clinical proof forthcoming.

Koch's theory of special infection is born out in the past history of cholera, and therefore, his investigations have given us still stronger ground for our former belief in the especially infectious nature of this disease, has furnished more evidence that the infectious matter is propagated from the excreta of the patient, and strengthens the belief that prevention through thorough disinfection is possible. The evidence in favor of the theory that cholera, diphtheria, scarlatina, variola, rubeola, and in fact all of the so called zymotic diseases are caused by micro organisms is rapidly increasing. The literature of germs is becoming voluminous, and extremely interesting. In a recent letter to your Chairman, that eminent teacher, Roberts Bartholow, makes use of the following language: "The battle of the bacilli is still raging with the odds in favor of Koch's comma bacillus. Klein, of London, a pupil of Stricker, of Vienna, denies the agency of the comma bacillus in causing cholera. It is alleged on the one hand that in a few instances cholera has been induced by the culture of the comma bacillus, and on the other hand Klein swallowed some without any effect. As Koch represents the Berlin school and Klein the Vienna, an agreement of views is not probable. If in any instance it is found that Koch's comma bacillus induces a cholera paroxysm his position is proved, for any number of negative facts cannot overcome one positive fact. As yet the evidence in favor of the comma bacillus is not sufficient to decide the question, but there is an increasing probability in favor of the view of its pathogenetic value."

In regard to Dr. Klein's opposition to Koch's theory, I would say that he has practically abandoned his views formerly expressed, and very recently made the following statement: "While the comma bacillus, in and of itself, is harmless, yet it does produce a virus which causes cholera." Speaking of the bacillus tuberculosis, the veteran Professor Austin Flint says: "The presence of a parasite in tuberculosis has been demonstrated. The great preponderance of evidence is in favor of the view that it is uniformly present in product recognized to be tuberculous. The conclusion which he reached was, that there was some essential connection between the presence of the parasite and the tuberculous disease; believes other causes may cooperate in the product of tubercle. But the presence of the specific parasite is essential." It will be noticed that this is a modification of the opinion expressed by Prof. Flint something over a year ago, and may be said to embody the prevailing opinion of a majority of the profession in regard to tubercle bacilli.

In the department of Special Therapeutics we have to notice the increasing tendency to hunt after specifics. In the opinion of some this practice is condemned, we think rather it should be commended. This restlessness in regard to and desire for improvement in our materia medica has been productive of much good. It has given us, I might say, nearly all our valuable remedies, and among them the last, but not the least, is the pain destroying cocaine, which latter remedy, although yet an infant, promises to speedily become a giant power for the relief of pain. A great effort toward more efficient therapeutical management of disease characterizes the work of the profession during the past year, and undoubted advancement has been attained.

The many revelations of the microscope have greatly added to our knowledge of the etiology of certain diseases, and have had the effect of remodeling our therapeutics to a certain extent. We all know that a belief in the germ doctrine has been productive of clean surgery, and thereby the saving of thousands of lives annually. That the use of antiseptics has made successful life saving operations that were formerly impracticable. The great principle in antiseptic surgery is the exclusion of micro-organisms, and therefore may mean simply perfect cleanliness. Thorough preventive medication is the principle involved, and implies the use of germicide remedies, the most popular of such remedies at the present time being the bi chl. mercury. How well germicides have served surgery any good surgeon can tell you. How much anti-germ remedies may do in preventing or controlling disease, is yet a subject for further consideration and experimentation.

While it is well known that we have but few remedies that should be regarded as specifics in any particular disease, we do know that so far as the destruction of infectious matter is concerned, we have remedies within the reach of all. When the same rules of cleanliness surround our patients suffering with a zymotic disease, as surround the patient of a Lister, then, and not till then, may we know what the practice of strict antisepticism may do for suffering humanity. It is true that all recognized that there was some necessity for cleanliness before the germ doctrine was advocated, but its promulgation has led to widespread knowledge in regard to the origin of many diseases, and never before were whole communities so well versed in the knowledge necessary to the prevention of what are now known to be preventable diseases—to prevent the occurrence is better than to cure a disease.

In the great advance in Sanitary Science, shines forth the grandeur of the work done by such investigators as Koch, and such experimenters as Lister. And now, what lessons may be learned from the investigations already made in the biology of germs? We may say that the idea of life in its simplest acceptation is that of vital activity. The increase of life of one particular form or sort may undoubtedly be destructive to life in other forms. The multiplication of organisms under certain conditions may, and probably does, give rise to the development of certain pathological conditions. What the laws of nature may be in regard to the development of infinitesimal organisms can only be learned through patient microscopic investigation. What the effect of the multiplication within our bodies of these micro-organisms is, can only be learned by the most careful, painstaking clinical observations

I think that we are now able to understand more fully that the history of life is a contention amid its various forms, and that all life, be it of whatever sort, has associated relations, and that these relations are of an important character We may now believe that some facts have been presented which lead us to realize that further investigation may give a bright light upon the pathway of pathological knowledge, that another milestone has been set upon that crooked pathway that will eventually lead mankind up the hill of science to a perfected system of pathology, and that with better knowledge in regard to all the various forms of life, our physiology will be greatly improved, our pathology approach perfection, and medicine finally become an exact science In order to assist in bringing about this happy consummation, it is necessary for us all to continue to observe and work

MEDICAL PROGRESS

MATERIA MEDICA AND THERAPEUTICS

Urethane as a Hypnotic—Dr von Jaksch (*Wein med Bl, Dtsch Med Ztg*) describes urethane as the ethyl ether of carbamic acid, NH CO C-H_5, a white, crystalline body, readily soluble in water, odorless, and tasting like saltpetre In doses of from four to fifteen grains, it acts as a hypnotic, affecting the brain, without notably influencing the peripheral sensory apparatus, hence it is not an anodyne Over all other pure hypnotics, however, it seems to have these advantages It is very well borne, it causes absolutely no complicating effects, and the sleep it produces resembles natural sleep in every respect The author thinks it will prove particularly serviceable among children and in cases of delirium tremens and mania —*N Y Med Jour*, Oct 3, 1885

Lantanine as a Febrifuge—This alkaloid, extracted by Negrete from the verbenaceous plant *Lantana brasiliensis*, is recommended by Dr E Buiza, of Lima (*Nouveaux Remedes*), as a substitute for quinine It retards the circulation and lowers the temperature, and is tolerated by the most delicate stomachs Intermittents that have proved rebellious to quinine have yielded to thirty grains of lantanine As an antipyretic, it is given in doses of a grain and a half, from ten to twenty of which are administered in twenty four hours For intermittent fever, it should be given immediately after a paroxysm, and in ninety-five cases out of a hundred the next paroxysm will not appear —*N Y Med Jour*, Oct 3, 1885

MEDICINE

A Case of Chronic Parenchymatous Nephritis Cured by the Subcutaneous Injection of Pilocarpine—Dr J Lazarus reports a case of chronic parenchymatous nephritis cured by hypodermatic injections of pilocarpine The patient, when first seen by Dr Lazarus, May 11th, had been ill several months, and his entire body was swollen and shapeless The legs, belly, and scrotum were enormously distended, and the last was attacked by superficial gangrene Both buttocks, both thighs, and both legs, as well as both feet, were the seat of pus discharging ulcers, due to phlegmonous inflammation of the subcutaneous cellular tissue A bedsore in the sacral region added to the pain and discomfort of the patient Great difficulty in breathing was also experienced, and profuse diarrhœa was present The urine was scanty, and had a specific gravity of 1040, and in consequence of the great amount of suspended material, composed of epithelial scales, detritus, etc, was cloudy, and even before the boiling point was reached was converted into a stiff jelly

On inquiry it was learned that the present condition began entirely unnoticed, and that in February the swelling of his feet led him first to seek professional advice Continuing his employment until April, he was at last compelled to remain in bed, owing to the increased swelling of his feet, and to extreme weakness, and to subject himself to systematic treatment

Treatment consisted in the employment of hot baths and in the medication generally employed in the treatment of Bright's disease, but no improvement resulted Dr Lazarus at once determined to resort to the hypodermatic use of pilocarpin Previous to the administration of the drug, a small quantity of brandy was given to support the heart, and followed by the injection into the thigh of one-third of a Pravaz's syringeful of the following

℞ —Pilocarpin muriat gr iss
Aquæ dist f ℥iss

The patient at once began to perspire abundantly, and for six hours was continuously bathed in perspiration, at the same time abundant salivary discharge was excited, amounting the first day after the injection to fully a quart

The only unfavorable symptoms noted subsequent to the administration of the drug, were repeated vomiting and difficulty in swallowing Brandy in quantities of a teaspoonful was administered two or three times hourly, and no symptoms of collapse were manifested The second day a half syringeful of the same solution was injected, the third day two-thirds, and the fourth day a whole syringeful, and for three weeks subsequently a like quantity was injected into each thigh alternately

The quantity of urine increased under the treatment from eleven ounces per diem, having a specific gravity of 1040 at the time of the first injection, to more than two quarts, with a specific gravity of 1002 at the twentieth injection With the twentieth injection the dropsy had entirely disappeared, and the extreme emaciation of the patient became apparent In the region of both trochanters, on the outer side of each thigh, as well as upon the outer side of the legs, there were large purse-like expansions of the cutis, due to phlegmonous inflammation in the subcutaneous cellular tissue, fluctuating and painful on movement

Believing that the small quantity of albumen still persisting in the urine, and the feverish condition of after these germs certainly requires the exercise of great, or exceptional skill, and the possibility of error is present in every examination. Nevertheless, although a positive indisputable demonstration in regard to germ influence may be impossible at this time, there may, happily, be further clinical proof forthcoming.

Koch's theory of special infection is born out in the past history of cholera, and therefore, his investigations have given us still stronger ground for our former belief in the especially infectious nature of this disease, has furnished more evidence that the infectious matter is propagated from the excreta of the patient, and strengthens the belief that prevention through thorough disinfection is possible. The evidence in favor of the theory that cholera, diphtheria, scarlatina, variola, rubeola, and in fact all of the so-called zymotic diseases are caused by micro organisms is rapidly increasing. The literature of germs is becoming voluminous, and extremely interesting. In a recent letter to your Chairman, that eminent teacher, Roberts Bartholow, makes use of the following language: "The battle of the bacilli is still raging with the odds in favor of Koch's comma bacillus. Klein, of London, a pupil of Stricker, of Vienna, denies the agency of the comma bacillus in causing cholera. It is alleged on the one hand that in a few instances cholera has been induced by the culture of the comma bacillus, and on the other hand Klein swallowed some without any effect. As Koch represents the Berlin school and Klein the Vienna, an agreement of views is not probable. If in any instance it is found that Koch's comma bacillus induces a cholera paroxysm his position is proved, for any number of negative facts cannot overcome one positive fact. As yet the evidence in favor of the comma bacillus is not sufficient to decide the question, but there is an increasing probability in favor of the view of its pathogenetic value."

In regard to Dr. Klein's opposition to Koch's theory, I would say that he has practically abandoned his views formerly expressed, and very recently made the following statement: "While the comma bacillus, in and of itself, is harmless, yet it does produce a virus which causes cholera." Speaking of the bacillus tuberculosis, the veteran Professor Austin Flint says: "The presence of a parasite in tuberculosis has been demonstrated. The great preponderance of evidence is in favor of the view that it is uniformly present in product recognized to be tuberculous. The conclusion which he reached was, that there was some essential connection between the presence of the parasite and the tuberculous disease, believes other causes may *cooperate in the product* of tubercle. But the presence of the specific parasite is essential." It will be noticed that this is a modification of the opinion expressed by Prof. Flint something over a year ago, and may be said to embody the prevailing opinion of a majority of the profession in regard to tubercle bacilli.

In the department of Special Therapeutics we have to notice the increasing tendency to hunt after specifics. In the opinion of some this practice is condemned, we think rather it should be commended. This restlessness in regard to and desire for improvement in our materia medica has been productive of much good. It has given us, I might say, nearly all our valuable remedies, and among them the last, but not the least, is the pain destroying cocaine, which latter remedy, although yet an infant, promises to speedily become a giant power for the relief of pain. A great effort toward more efficient therapeutical management of disease characterizes the work of the profession during the past year, and undoubted advancement has been attained.

The many revelations of the microscope have greatly added to our knowledge of the etiology of certain diseases, and have had the effect of remodeling our therapeutics to a certain extent. We all know that a belief in the germ doctrine has been productive of clean surgery, and thereby the saving of thousands of lives annually. That the use of antiseptics has made successful life saving operations that were formerly impracticable. The great principle in antiseptic surgery is the exclusion of micro-organisms, and therefore may mean simply perfect cleanliness. Thorough preventive medication is the principle involved, and implies the use of germicide remedies, the most popular of such remedies at the present time being the bi chl mercury. How well germicides have served surgery any good surgeon can tell you. How much anti germ remedies may do in preventing or controlling disease, is yet a subject for further consideration and experimentation.

While it is well known that we have but few remedies that should be regarded as specifics in any particular disease, we do know that so far as the destruction of infectious matter is concerned, we have remedies within the reach of all. When the same rules of cleanliness surround our patients suffering with a zymotic disease, as surround the patient of a Lister, then, and not till then, may we know what the practice of strict antisepticism may do for suffering humanity. It is true that all recognized that there was some necessity for cleanliness before the germ doctrine was advocated, but its promulgation has led to widespread knowledge in regard to the origin of many diseases, and never before were whole communities so well versed in the knowledge necessary to the prevention of what are now known to be preventable diseases—to prevent the occurrence is better than to cure a disease.

In the great advance in Sanitary Science, shines forth the grandeur of the work done by such investigators as Koch, and such experimenters as Lister. And now, what lessons may be learned from the investigations already made in the biology of germs? We may say that the idea of life in its simplest acceptation is that of vital activity. The increase of life of one particular form or sort may undoubtedly be destructive to life in other forms. The multiplication of organisms under certain conditions may, and probably does, give rise to the development of certain pathological conditions. What the laws of nature may be in regard to the development of infinitesimal organisms can only be learned through patient microscopic investigation. What the effect of the multiplication within our bodies of these micro organisms is, can only be learned by the most careful, painstaking clinical observations

I think that we are now able to understand more fully that the history of life is a contention amid its various forms, and that all life, be it of whatever sort, has associated relations, and that these relations are of an important character We may now believe that some facts have been presented which lead us to realize that further investigation may give a bright light upon the pathway of pathological knowledge, that another milestone has been set upon that crooked pathway that will eventually lead mankind up the hill of science to a perfected system of pathology, and that with better knowledge in regard to all the various forms of life, our physiology will be greatly improved, our pathology approach perfection, and medicine finally become an exact science In order to assist in bringing about this happy consummation, it is necessary for us all to continue to observe and work

MEDICAL PROGRESS

MATERIA MEDICA AND THERAPEUTICS

Urethane as a Hypnotic—Dr von Jaksch (*Wein med Bl, Dtsch Med Ztg*) describes urethane as the ethyl ether of carbamic acid, NH CO C-H_5, a white, crystalline body, readily soluble in water, odorless, and tasting like saltpetre In doses of from four to fifteen grains, it acts as a hypnotic, affecting the brain, without notably influencing the peripheral sensory apparatus, hence it is not an anodyne Over all other pure hypnotics, however, it seems to have these advantages It is very well borne, it causes absolutely no complicating effects, and the sleep it produces resembles natural sleep in every respect The author thinks it will prove particularly serviceable among children and in cases of delirium tremens and mania —*N Y Med Jour*, Oct 3, 1885

Lantanine as a Febrifuge—This alkaloid, extracted by Negrete from the verbenaceous plant *Lantana brasiliensis*, is recommended by Dr E Buiza, of Lima (*Nouveaux Remedes*), as a substitute for quinine It retards the circulation and lowers the temperature, and is tolerated by the most delicate stomachs Intermittents that have proved rebellious to quinine have yielded to thirty grains of lantanine As an antipyretic, it is given in doses of a grain and a half, from ten to twenty of which are administered in twenty four hours For intermittent fever, it should be given immediately after a paroxysm, and in ninety five cases out of a hundred the next paroxysm will not appear —*N Y Med Jour*, Oct 3, 1885

MEDICINE

A Case of Chronic Parenchymatous Nephritis Cured by the Subcutaneous Injection of Pilocarpine—Dr J Lazarus reports a case of chronic parenchymatous nephritis cured by hypodermatic injections of pilocarpine The patient, when first seen by Dr Lazarus, May 11th, had been ill several months, and his entire body was swollen and shapeless The legs, belly, and scrotum were enormously distended, and the last was attacked by superficial gangrene Both buttocks, both thighs, and both legs, as well as both feet, were the seat of pus discharging ulcers, due to phlegmonous inflammation of the subcutaneous cellular tissue A bedsore in the sacral region added to the pain and discomfort of the patient Great difficulty in breathing was also experienced, and profuse diarrhœa was present The urine was scanty, and had a specific gravity of 1040, and in consequence of the great amount of suspended material, composed of epithelial scales, detritus, etc, was cloudy, and even before the boiling point was reached was converted into a stiff jelly

On inquiry it was learned that the present condition began entirely unnoticed, and that in February the swelling of his feet led him first to seek professional advice Continuing his employment until April, he was at last compelled to remain in bed, owing to the increased swelling of his feet, and to extreme weakness, and to subject himself to systematic treatment

Treatment consisted in the employment of hot baths and in the medication generally employed in the treatment of Bright's disease, but no improvement resulted Dr Lazarus at once determined to resort to the hypodermatic use of pilocarpin Previous to the administration of the drug, a small quantity of brandy was given to support the heart, and followed by the injection into the thigh of one-third of a Pravaz's syringeful of the following

℞ —Pilocarpin muriat	gr iss
Aquæ dist	f ℥iss

The patient at once began to perspire abundantly, and for six hours was continuously bathed in perspiration, at the same time abundant salivary discharge was excited, amounting the first day after the injection to fully a quart

The only unfavorable symptoms noted subsequent to the administration of the drug, were repeated vomiting and difficulty in swallowing Brandy in quantities of a teaspoonful was administered two or three times hourly, and no symptoms of collapse were manifested The second day a half syringeful of the same solution was injected, the third day two-thirds, and the fourth day a whole syringeful, and for three weeks subsequently a like quantity was injected into each thigh alternately

The quantity of urine increased under the treatment from eleven ounces per diem, having a specific gravity of 1040 at the time of the first injection, to more than two quarts, with a specific gravity of 1002 at the twentieth injection With the twentieth injection the dropsy had entirely disappeared, and the extreme emaciation of the patient became apparent In the region of both trochanters, on the outer side of each thigh, as well as upon the outer side of the legs, there were large purse-like expansions of the cutis, due to phlegmonous inflammation in the subcutaneous cellular tissue, fluctuating and painful on movement

Believing that the small quantity of albumen still persisting in the urine, and the feverish condition of the patient, were a result of these purulent collections, Dr Lazarus opened the pouches at brief intervals, and treated them antiseptically with iodoform gauze and drainage, they rapidly healed, as did also the bedsore and superficial gangrene of the scrotum At the same time the secretion of urine rapidly increased, so that the quantity passed exceeded the normal, reaching three to four quarts daily The cicatrization of the last suppurating cavity was followed by the entire disappearance of albumen from the urine The patient was finally subjected to further treatment by hot baths, and daily increased in strength, his health finally becoming entirely restored —*Wiener med Presse*, August 2, 1885 —*Medical News*, September 26, 1885

ARSENIC IN LYMPHADENOMA —DR STEPHEN MONCKTON reports the following interesting case showing the value of arsenic in lymphadenoma

During the first week of March, 1885, J G, aged 57, married, of sober and healthy antecedents, presented himself to me as an out patient at the West Kent General Hospital As I had known him before, it could be seen at once that he was thin and sickly At first, no definite complaint on his part could be elicited, but mention was made of a swelling in the armpit This led to his being completely stripped, when a considerable bunch of enlarged glands was seen at once above each collar bone, in each armpit, and in each groin He did not think they could have existed more than six or eight weeks, but this was doubtful Our district meeting was to come off at the hospital on March 27 I persuaded him to come for exhibition, and he was willing enough to do so, on that occasion, being again stripped, he was examined by twenty or thirty medical friends The gland bunches stood out even bigger, in average bulk, they may be spoken of as a large handful each

At the same meeting, our attention was called to a new form of pill preparation carried out at Hamburg, the principle being to invest the drug in keratin, or horn gelatine, in such a way as to render the pill insoluble in the acid fluids of the stomach, while it becomes readily dissolved in the alkaline contents of the upper bowel It occurred to me that the delayed solution ought to be advantageous when applied in the case of arsenic, and also that arsenic was the most hopeful remedy for the patient with lymphadenoma I procured a supply of the pills through the firm of Bell & Co, Oxford Street, each pill being stated to contain one thirteenth of a grain of arsenious acid The pills were commenced about the 4th or 5th of April, and continued, one thrice daily, till June 4 No disturbance of any sort resulted, he came once a week to the hospital, declared that he was being cured, and to my eyes, and to those of a colleague and the house-surgeon, it was certain that every bunch of glands steadily and considerably diminished

On June 4 he came, a stricken and altered man, having been seized forty-eight hours before with pleuro-pneumonia, then fatally rife He was sent back to the care of his country medical man, and died within a fortnight That gentleman remarks that, at the last, the bunches of glands had almost disappeared

Whether the fatal attack was an accidental episode, or whether it was based on intra-thoracic glandular mischief, cannot be known Whether, if he had escaped the pulmonary attack, the original disease would have continued to yield constitutionally and locally, is equally uncertain

I ask the publication of this case on two grounds alone first, because in no other case in my life did I ever see lymphadenomatous masses diminish under any treatment whatever, and, second, because, as two or three other recent cases have also done, it illustrates the tolerance of arsenic which this special mode of treatment seems to confer —*British Med Journ*, Sept 26, 1885

ANTIPYRIN IN HECTIC FEVER —At the meeting of the Cambridge Medical Society, on August 7, DR MACALISTER gave an account of the nature and uses of this drug, and showed the temperature charts of two patients recently treated in Addenbrooke's Hospital Both suffered from phthisis, apparently limited to the apices of the lungs In one case, that of a man, aged 25, hectic fever appeared, the morning temperature was 98°, the evening temperature 102 ° Antipyrin in fifteen grain doses, administered twice in the course of the afternoon, promptly reduced the range of daily oscillation to 1°, about the normal temperature An omission of the drug was followed by recurrence of the hectic, but again the temperature fell, and was maintained low by five grain doses given thrice a day At the same time, the patient became more comfortable and slept better, some tendency to sweating was checked by minim doses of liquor-atropiæ sulphatis The other case, that of a woman, aged 44, with still more urgent symptoms, and a temperature ranging from 98° to 103°, was treated in a similar way, with equally good results In neither patient was any rash or marked nausea produced, and both were in a little more than a fortnight so much better that they were transferred to the out patient department Dr MacAlister thought that, in many cases in which fever was a symptom, it was sound practice to attempt to reduce the temperature for its own sake Antipyrin, of all the anti pyretics he had tried, seemed to be the most powerful with the fewest disadvantages —*British Med Journ*, Sept 26, 1885

FRIEDRICHSHALL WATER IN HABITUAL CONSTIPATION —DR WILLIAM MURRELL, in a note on this subject, says Friedrichshall has a special constitution, which secures to it marked preference over the ordinary sulphate of magnesia waters Its special advantages are probably largely due to its combination of chlorides with sulphates It is not merely a saline aperient, but it has valuable properties in influencing tissue-change and promoting excretion of uric acid Its use is attended with excellent results is cases of congestions of the liver and kidney, as a corrective of the digestion, and as what may be familiarly described as a tonic-aperient —*Brit Med Journal*, Sept, 19, 1885

THE NINTH INTERNATIONAL MEDICAL CONGRESS

Since the meeting of the Committee of Arrangements in New York, Sept 3 and 4, and the final adoption of the Rules regulating the membership and business of the Congress, and the transference of its future management under the Rules adopted, to an Executive Committee of the Congress itself, the expressions of approval in the medical press have been multiplying, and the general feeling of increased confidence in the success of the Congress is apparent throughout the profession The *Medical Times* and *College and Clinical Record*, of Philadelphia, the *New England Medical Monthly*, *Gaillard's Medical Journal* and the *Sanitarian*, of New York, the *Journal and Examiner*, of Chicago, the *Detroit Lancet*, the *Medical Herald*, of Louisville, the *Courier-Record of Medicine*, the *Southern Practitioner*, of Nashville, *Daniel's Texas Medical Journal* the *Southern Dental Journal*, and others, have given the most decided expressions of approval of the Rules adopted and of the present Preliminary Organization of the Congress We quote the following from the editorial in the *Philadelphia Medical Times* as fitly representing the sentiments of all the journals named "The list of appointments and nominations with Dr Austin Flint at the head, is one which, we think, will meet with the endorsement of the profession generally It is seen that when the time for final action came, the members of the Committee, rising to the responsibility resting upon them, acted with marked discretion, good judgment, and an evident desire to discharge faithfully and impartially the duty for which they were appointed It is hoped, the way being now open for harmonious cooperation, that all may unite in striving to secure the success of the Congress, the prospects for which are brighter at present than they have been since the invitation to meet in 1887 in Washington was accepted"

At the quarterly meeting of the Cumberland County, Pa, Medical Society held Oct 6, the following resolution was unanimously adopted "*Resolved*, That this Society endorse the action of the Committee appointed by the American Medical Association, in relation to the International Medical Congress to be held in the City of Washington, D C, in 1887"

We have assurances from several of those whose names have been heretofore announced as withdrawing from all active participation in the Congress "as now (formerly) proposed to be organized," that they are entirely satisfied with the present Rules and organization, and will personally aid in promoting the success of the Congress Not only is there thus a much improved feeling at home, but there is evidence of a better understanding of the affairs of the Congress in, at least, some of the journals of Great Britain The *London Lancet*, of October 3, has an editorial decidedly opposing any attempt to withdraw the Congress from this country, and expressing much confidence in its entire success at the appointed time in Washington, and the *Provincial Medical Journal* has much more in the same direction

In the midst of these general indications of satisfactory progress, it is amusing to witness the progress of that trio of chronic grumblers, the *Philadelphia Medical News*, the *New York Medical Journal*, and the *Medical Record* Being no longer able to find any fault with either the Rules or the *personnel* of the present Preliminary Organization of the Congress, they have suddenly become much concerned for the honor and dignity of the American Medical Association, on account of an alleged declaration of independence on the part of the Executive Committee of the Congress, and they affect to wonder why the Original Committee on Organization did not take the same easy method to free itself from the authority of the Association Their anxiety in this direction, however, is entirely unnecessary The Committee of Arrangements appointed by the American Medical Association, in compliance with the instructions of the Association, has revised the Rules previously adopted, completed the general Preliminary Organization of the Congress on a basis fairly representing the profession of the United States, including an able Executive Committee, and transferred all the further management of the proposed Congress to such Committee Having thus completed the work for which it was appointed, without any signs of rebellion or resolution of independence, that Committee remains ready to render an account of its stewardship at the next meeting of the Association and receive any further instructions that body may see fit to give. But the Executive Committee of the Congress, composed of other men entirely, in accepting the important and responsible positions and duties assigned to them by the Committee of Arrangements, accompanied their acceptance with the condition that their actions, while made in obedience to the Rules of Organization, should not be subject to revision by any other organization, a condition neither inappropriate nor in any degree disrespectful to the American Medical Asssociation, or its Committee of Arrangements. The reason why the Executive Committee of the first Preliminary Organization could not make the same condition or declaration, was because it had been so largely made up of the same individuals as the Committee by which it was appointed that the *personnel* of the Executive Committee of the Congress and that of the Committee on Organization created by the Association, were the same—one and inseparable. Consequently, when the Association exercised its right to re model the Committee on Organization, it disturbed the whole machinery. On the other hand, the present Committee of Arrangements, notwithstanding all the accusations of selfishness and personal ambition heaped upon its members by this same trio of journals, has been patriotic and wise enough to avoid all self-appointments to office, and to give to the Ninth International Medical Congress an independent and self sustaining Preliminary Organization, guided only by Rules sufficiently liberal to allow that freedom of executive action which is necessary to ensure success.

OERTEL'S TREATMENT OF DISORDERS OF THE CIRCULATION.

Within the last year a medical work has appeared in Germany, which has met with such a demand from both the profession and the laity, that a second edition has been issued. The work is of interest to the public mainly, we presume, because it sets forth the author's method of reducing superfluous fat, to the medical man because of its original, and as it would seem highly effective treatment of disorders of the circulatory and respiratory apparatus. So far as we are able to ascertain the work has not yet appeared in this country, either in the original or in translation. However, the *Berliner Klinische Wochenschrift*, No. 33, 1885, contains a digest of its salient points, and for the sake of our readers, we propose to recapitulate a few of its main features.

The work in question is by M. J. OERTEL, of Munich, and is entitled "Therapie der Kreislaufs-storungen, Kraftabnahme des Herzmuskels, Ungenugender Compensationen bei Herzfehlern, Fettherz und Fettsucht, Veranderungen im Lungenkreislauf, etc." The object to be gained by the author's therapeutic measures is the removal or amelioration of the various symptoms which depend primarily upon disorders of the circulatory and respiratory organs, such as cardiac debility, fatty heart, general obesity, valvular disease of the left side of the heart, and impediment from any cause to the pulmonary circulation. These symptoms, such as dyspnœa, sweating, scanty urination with albuminuria, cardiac palpitations with a sense of oppression, hæmorrhagic spots upon the extremities, œdemata, etc., result directly from loss of the normal equilibrium of the circulating fluids, that is, venous plethora on the one hand, and arterial depletion on the other. Death results, in such cases, when not from apoplexy or intercurrent affections, either from secondary disease of the kidneys and dropsy, or from cardiac paralysis. This last again, is the consequence of organic lesions, fatty infiltration or degeneration, atrophy, etc., or, if the cardiac muscle be healthy, it is the result of exhaustion of the heart or of paralysis of its nerve apparatus from overdistension of its cavities with blood.

An opportunity was given Dr. Oertel to test his skill in the person of a physician who had been humpbacked since childhood. Of late the embarrassment to the circulation and respiration, occasioned by the deformity, had greatly increased, in consequence, the author thinks, of corpulence and the habit recently formed of taking about seven times as much liquid into his system as had been his wont. This additional burden, the already hypertrophied heart was unable to sustain and dangerous symptoms followed. The indication then was to reduce the bulk of fluid in the system as well as the superfluous fat. Blood-letting was inadmissable, since it would result in hydræmia, and as the kidneys were in a state of chronic hyperæmia, the water had to be eliminated by the skin and lungs. Accordingly careful experiments were instituted to ascertain the most effective mode of accomplishing this. Accurate measurements showed that the greatest amount of water was eliminated, first, during mountain climbing, secondly, though not constantly, after hypodermic injections of pylocarpine, thirdly, by hot-air baths, and lastly by steam baths. In this way a man of 165 pounds in weight, could be made to lose from a tenth to a fifth of the entire weight of his bodily fluids. At the same time of course a minimum supply of liquid nourishment should be injected, care being exercised that the urine voided, be sufficient in quantity to hold its solid ingredients in solution.

A second indication was to get rid of superfluous fat. This was to be attained by appropriate diet and mode of life. In attempts of this kind the author lays down the principle that care must be exercised to determine whether or not the heart be fatty, since upon its condition must depend the dietary. If the heart be sound, Oertel restricts the daily allowance of food to at least 156 grammes of albumen, forty-three of fat, and 114 of hydrocarbons. If owing to sluggish pulmonary circulation, from any cause, the oxygenation of the blood is inadequate to the consumption of the amount of these carbohydrates, they must be cut down to about twenty-five grammes of fat and seventy of the sugar and starches, while the albumen is increased to 170 grammes *per diem*. In order to facilitate the digestion of so large a quantity of albuminous food, by keeping the digestive fluids as concentrated as possible, he allows no liquid to be taken with the meal and not until an hour and a half subsequently. Furthermore, he found by experiment, that where restricted diet is inadmissible, the fat of the body can be reduced by the amount of water injested. The effect, he thinks, is to invigorate and accelerate the circulation, and to cause the obliteration of vessels supplying the adipose tissue, its nutrition being thus abolished and its elements absorbed. By a series of careful experiments he ascertained the comparative amounts of urine voided and water consumed, and found that, even if the latter be very limited, the former is largely in excess. Contrary to other experimenters he also ascertained that the white of eggs eaten in large quantities does not appear in the urine. Next he tried the effect of mountain climbing in restoring the equilibrium between the venous and arterial systems, believing venous stasis would be overcome by muscular contractions and the increased suction force of the thoracic viscera, on the one hand, while on the other, the pulmonary circuit would be more completely emptied and the arterial system better filled.

By means of Von Basch's sphygmomanometer, Sommerbrodt's sphygmograph and two self registering thermometers, one in the mouth, the other in the axilla, he discovered that in mountain climbing the blood-pressure is at first augmented, soon followed by diminution of the arterial tension and dilatation of the vessels, which effect is perceptible as late as the following day. Owing to the muscular activity, the generation and elimination of bodily heat are increased, thus favoring a more active tissue metamorphosis. The depletion of the venous system is furthermore promoted by the excessive elimination of water by skin and lungs. Observations upon thirty-five perfectly healthy individuals showed but in one instance under the effect of climbing, traces of serum albumen, and in two, traces of hemi albumen in the urine. The effect of preexisting albuminuria was not noted. Oertel is of the theoretic opinion that climbing would exert a beneficial influence upon a heart which, although weak, yet possesses no serious organic disease or degeneration of its muscular elements. In such a case as that of the physician already cited, such vigorous exertion might be hazardous, and experience alone could determine the result. He thinks the effect ought to be to develop an advantageous hypertrophy through the augmented force of its contractions, just as exercise develops any other muscle.

The plan of treatment, the principles of which we have necessarily so briefly stated, was tried upon the physician with brilliant results. By methodical and gradually increased mountain climbing, appropriate diet and lessened ingestion of liquids, the venous stasis was relieved, the pulse became full, slow and regular, and the respiration deep and easy. The heart was evidently reinvigorated. The corpulence was lost entirely, but the albuminuria did not wholly disappear until after three years, and the last vestige of dropsy, not until the treatment had been followed for more than two years. In all, Oertel has treated fifty one cases of disordered circulation after this fashion.

This mode of treatment is one that recommends itself to careful attention if for no other reason, because it does away with the deleterious effects of the prolonged employment of internal remedies which are but too often powerless. It is therefore highly rational, and the patient and physician alike should be consoled for the length of time necessary for this system of therapeutics by the reflection that a chronic disease requires chronic treatment.

ABDOMINAL AUTO TRANSFUSION IN ACUTE POST PARTUM CEREBRAL ANÆMIA

Dr. Robert Koppe, of Moscow (*Centralblatt für Gynakologie*, No. 38, 1885), narrates the history of an interesting obstetrical case, in which abdominal auto transfusion was successfully practiced in acute post partum cerebral anæmia. The patient was a primipara, 24 years old. The abdomen was enormously distended, as the result of twin pregnancy, complicated by pelvic contraction and puerperal endometritis The first child, presenting by the vertex, was delivered after the performance of craniotomy The second child, presenting by the breech, was delivered by energetic manual extraction Although profoundly asphyxiated, the child was resuscitated The placentæ were normally expelled, and the uterus contracted well without the loss of any considerable quantity of blood

The labor seemed to have reached a happy ending, when the woman suddenly became pale, and appeared to be on the verge of collapse No external hæmorrhage was visible,and the uterus was firmly contracted Rupture of the uterus, with the escape of blood into the peritoneal cavity, could be excluded Dr Koppe accordingly concluded that the syncope was caused by the collection of blood in the abdominal venous system Such an hypothesis was logical The taut abdominal parietes of a primipara, the excessive distension of the uterine cavity by twin pregnancy and puerperal endometritis, and the contracted pelvis, were factors sufficient to account for an extreme elevation of intra abdominal pressure The dilated abdominal venous trunks, suddenly relieved of this pressure by the evacuation of the uterine contents, must have received from the systemic circulation a corresponding quantity of blood Literally, "an internal hæmorrhage within the system of blood-vessels" had occurred The cerebral anæmia and collapse were the most striking symptoms of this internal hæmorrhage

Depression of the head, the exhibition of large quantities of port wine and cognac in hot tea, had no effect on the woman's condition On the contrary, the pallor increased, the lips became colorless, and the radial pulse could not be felt As a last resort, an eider-down pillow was placed upon the abdomen, adapted as a compress, and firmly secured by turns of a roller-bandage around the back and sacrum At once, the natural color began to return to the skin and mucous membranes, and consciousness was gradually restored At the expiration of two weeks, the eider down pillow was exchanged for a tight-fitting abdominal supporter

Dr Koppe's method, thus briefly sketched, admits of extensive application Acute cerebral anæmia frequently supervenes secondarily in shock occurring in child-bed It is highly probable that primary acute cerebral anæmia is confused with shock Under these conditions, Dr Koppe's "monster abdominal tampon" might render efficient service

Abdominal auto transfusion may be re-inforced by a method more particularly practiced, at the present time, in the obstetrical clinics of Vienna We are under the impression that the plan was proposed by Esmarch After depressing the head of the patient, and elevating her lower extremities, plain, rubber, roller-bandages are applied, commencing at the toes and extending up to the hips A considerable quantity of blood is thus forced into the blood vessels of the trunk and upper portions of the body

SOCIETY PROCEEDINGS

AMERICAN GYNECOLOGICAL SOCIETY

Tenth Annual Session, held at Washington, Sept 22, 23 and 24, 1885

(Continued from page 445)

TUESDAY, SEPT 22—AFTERNOON SESSION

DR JOSEPH TABOR JOHNSON, of Washington, reported

FOUR CASES OF OOPHORECTOMY, WITH REMARKS

Case 1—Miss M had suffered severely from chronic oophoritis and menstrual epilepsy She was at that time 29 years of age, and had suffered for fourteen years There was constant pain in both ovaries, but most of the suffering was on the left side For two weeks out of every month she was under the care of an attendant Her education had been neglected, and she was in an almost beastly condition She had been under the care of skilful physicians, and almost everything had been tried Oophorectomy was therefore decided upon, and performed August 17, 1882 Both ovaries and one fallopian tube were removed For several months she had no periods and no spasms Gradually her menses returned, and with them the convulsions in milder form She is now menstruating with more regularity than before the operation

Case 2—Miss W, age 21 From being in affluence she had been reduced to the necessity of earning her living Five years before coming under observation she took a severe cold at the monthly period Since then she has suffered from chronic ovaritis She also had leucorrhœa and a displaced uterus, for which she was treated without material benefit I treated her for three months without benefit, and then removed the ovaries She made a rapid recovery and has since been free from pain

Case 3—Miss S, age 24, had been a great sufferer from dysmenorrhœa and reflex symptoms She suffered with burning pain in the abdomen and head for ten days preceding menstruation For several months there had been no flow, but the distressing symptoms continued Both ovaries and tubes were removed She made a rapid recovery and continues healthy

Case 4—Mrs ——, age 40, the mother of three children, had suffered with pain in the left ovary for twenty years She had a lacerated cervix and perneum which had been restored without improving the other symptoms. She had been under treatment for ten years, but was practically bed-ridden for three weeks out of every month. She wished to have the ovaries removed, but I advised her to wait five years longer, until the menopause would accomplish the same result. She, however, insisted on the operation, and I performed it last February. She did well for three days, when vomiting set in and she died exhausted on the sixth day.

The speaker then referred to the great importance of an early diagnosis in such cases in order that the operation might be performed before numerous adhesions had taken place, and before the general condition had become so depressed, referring to the statistics of various operators in confirmation of his statements. He thought that many cases which are now lost from prolonged operations, necessitated on account of the numerous adhesions, might be saved if there were means by which an early diagnosis could be made.

Dr. R. S. Sutton, of Pittsburgh, said that all admitted that a woman with a cystic tumor of the ovary is doomed to death, if the tumor is not removed, but when she is suffering from some disease of the ovary which does not give tangible evidence of its presence, the surgeon has often difficulty in deciding as to the question of operation. It may be that under ether and with bi-manual palpation it is utterly impossible to detect any evidence of disease of the ovaries or tubes, and yet the ovaries may be at the bottom of the trouble. Should the woman be allowed to go on suffering because evidence of a disease that will justify an operation can not be obtained? He remarked that it was better to give the woman the benefit of the doubt and open the abdomen and examine the organs. He did not believe that any one could tell the exact condition of the ovaries before opening the abdomen. He also stated that it has now come to be the practice in obscure conditions in women for which no explanation can be found, and in which it is probable that the ovaries or tubes are at fault, to make an exploratory operation. As a rule exploratory operations are safe. He had yet to open the first abdomen and fail to find disease of the ovaries or tubes. He presented a specimen which he had removed from a woman sent to him for operation for lacerated cervix. There were symptoms which he could not refer to the condition of the cervix. On careful examination he found evidence of disease of the ovaries. He removed both ovaries, one contained a dermoid cyst and the other had undergone cystic degeneration.

Dr. Baker said that this operation opens up a large field of usefulness to the gynæcologist, and of benefit to woman, but there is great danger of the pendulum swinging too far and the operation being performed too frequently. He would not discourage the operation in properly selected cases. An operation which gives such brilliant results in properly selected cases is almost certain to be carried too far. The greater skill shown is in curing these patients without the removal of organs. All will come to a better understanding as to when the operation should be performed and when not, by studying the organ itself very carefully in those cases in which it has been removed. He remarked that in all descriptions of the operation, there should be an accompanying report of the microscopical examination. The question of early diagnosis had been referred to, and this is a matter of the greatest importance. The ovaries and tubes are not the easiest organs to examine. Even where the ovaries are adherent to surrounding tissues it was often extremely difficult to determine this fact. Exploratory operation may be the only way of determining this fact. Where exploratory incision has been made and the organs found healthy, so far as their gross appearance is concerned, he said that they should be put back and the abdomen closed, even if the woman suffers excruciating pain with the menstruation. He believed if the same perseverance and good judgment were manifested in these cases as in others, many of them could be cured without operation. He could not agree with the author of the paper in regard to the increased danger from the presence of adhesions. The only death which he had seen was in a case where there were no adhesions and the operation was performed with ease. In many of the other cases there had been extensive adhesions.

Dr. T. A. Emmett, of New York, remarked that what he had to say was rather in the form of a protest. He was not an advocate of the operation, and he thought that more harm than good had been done by its performance. There are cases where the operation must be done. Where there is salpingitis with the tubes filled with pus the operation is certainly indicated. That the operation should be done, as it frequently is, for the relief of so many symptoms, is, he thought, a reproach on the profession. He could not advocate the opening of the abdomen for the purpose of making a diagnosis. If the diagnosis could not be made beforehand, he did not think it justifiable to run the risk of opening the abdomen. For three years he had been looking for cases in which he considered the operation indicated, and he had seen but two such cases. One was a typical case in which there had been several attacks of peritonitis, following gonorrhœa. He found both tubes as large as his wrist and presenting the twisted appearance described by Tait. The history indicated the existence of pus. He urged an operation, but the patient refused. She was seen by Dr. Thomas, who also recommended an operation. She insisted upon staying in Dr. Emmett's private hospital. He stated that for five months there was no improvement. The treatment consisted of hot water injections, keeping the bowels regular, applications of iodine daily, and attention to the general health. After several months the tubes began to diminish in size, and in the course of a year the accumulation had entirely disappeared and she left the hospital apparently a well woman. The second case was similar. She also refused an operation. She is now no worse, and in some respects better, than she was some years ago.

Dr. Wm. T. Lusk said that great caution must be exercised in the performance of this operation. He had recently seen a lady who had pelvic inflammation following the use of a stem pessary. There is now thickening of the broad ligaments. She visited a gynæcologist, who advised the removal of the ovaries. He could find no evidence of disease of the ovaries or tubes. In many of the operations which he had seen there had been no evidence of disease in the ovaries or tubes removed. He did not condemn the operation. He had operated in four cases in which there was distinct evidence of disease of the tube with good success.

Dr. H. P. C. Wilson thought that many cases have been operated on which should have been left alone, but there are many cases which nothing but this operation will relieve.

Dr. E. W. Jenks was aware of several cases in which the operation had been performed without benefit. Where the ovaries and tubes are diseased, there can be no question as to the propriety of its performance. In many of these cases of so called hystero epilepsy, which are often nothing more than hysteria, he considered the removal of the ovaries and the stopping of the prospect of the patient becoming a mother, a positive wrong. He said the exploratory operation was not free from danger, as he knew of four deaths under these circumstances in which no disease of the ovary was found.

Dr. T. A. Reamy, of Cincinnati, said one woman was sent to him with dysmenorrhœa and hysterical symptoms, with the request that he should remove the ovaries. It was a well marked case. Five months' treatment of the cavity of the uterus, with change in her surroundings and general treatment, resulted in entire recovery. He has had several other striking cases. It is the exception to find the ovary healthy in women after the age of forty. He had been making these observations for ten or twelve years.

Dr. Emmett remarked that the operation is sometimes done for dysmenorrhœa. He thought that it should never be done for this condition. He considered dysmenorrhœa a neuralgic condition, the result of anæmia. When the dysmenorrhœa is relieved by operation, it is because the general nutrition is improved by the removal of the ovaries.

Dr. Sutton said he agreed with Dr. Baker that where, in an exploratory operation, the ovaries and tubes are found to be healthy, they should not be disturbed.

Dr. M. D. Mann, of Buffalo, said that Dr. Emmett had made the statement that dysmenorrhœa is a neuralgic condition, and is not an indication for the operation. Although it may be neuralgic, he thought that the neuralgic condition may become so firmly established that it can not be relieved without taking out the seat of the neuralgia. In two such cases he considered the operation indicated. In one the patient was free from pain only three days of each month. He advised the operation, which was performed by Dr. Clark, of Niagara. The second case was his own. The woman had suffered for a number of years with excruciating pain. The ovaries were enlarged and tender. The whole abdomen was tender. The ovaries were removed and the patient entirely recovered her health. He could not admit that there are no cases of ovarian dysmenorrhœa which can be relieved by the operation, but he thought they were rare.

Dr. Johnson said he did not recommend the operation except under well-marked conditions. He agreed with those who fear that the operation may be performed oftener than necessary. Its use in nervous and neuralgic conditions is not always as beneficial as in some other conditions, as myoma of the uterus, for example.

Wednesday, September 23—Second Day.

The President, Dr. Wm. A. Howard, of Baltimore read the *Annual Address*, entitled

TWO RARE CASES IN ABDOMINAL SURGERY.

The speaker held that all cases, whether successful or not, should be put on record, in order that the knowledge of such affections might be increased. The paper described two rare cases of exceptional interest in which the doctor was completely baffled in the diagnosis, and declined to make one.

Case I.—S. H., negress, age 24 years, married, presented herself at the dispensary of the University of Maryland, April 20, 1882. She was seen by the clinical assistant and the following notes made. Menstruation appeared at the age of 14, and had been regular and normal. She was the mother of five children, the youngest of whom was two months old. She had never had a miscarriage. Some days after delivery, she noticed an enlargement in the lower portion of the abdomen, which gradually extended in the middle line until it reached the umbilicus, and was attended with bearing down pains and frequent micturition. On examination, fluctuation was well marked all over the abdomen, with decided resonance about the umbilicus. There was dulness on percussion and bulging in both flanks. Six weeks later she returned to the dispensary, and at this time, the resonance at the umbilicus had disappeared, and the umbilicus at this time projected. I saw her for the first time two weeks after this observation was made. At this time she was quite sick, the temperature being 102,° the pulse 132, and the respiration 32 per minute. Examination showed the presence of fluid in the pleural sac. There were also some crackling râles heard through the lung. The abdomen was as large as at seven months' pregnancy, and was remarkably protuberant in the centre. There was complete dulness over the entire abdomen, not changed by change of position. There was no evidence of a solid tumor, but it had every appearance of a simple unilocular cyst. Vaginal examination showed the uterus well in front of the tumor, and the sound gave a measurement of two and three fourths inches.

The question which arose was as to the nature of the tumor. Was it ovarian? The extreme infrequency of ovarian tumors in the negro race was against this view. The rapid growth of the tumor was also opposed to this view. The next affection considered was fibro-cystic tumor of the uterus. This is exceedingly rare. The speaker had seen but one such case in the negro. In that case, the cyst was filled with pus The patient was operated upon with a fatal result Such tumors are rare before the age of 35 They usually develop slowly There was no menstrual disturbance in this case For these reasons, fibro cystic tumor was excluded

Was it a parovarian cyst? These usually develop even more slowly than ovarian cysts They are usually flaccid They contain a thin liquid, are comparatively rare, and do not affect the general health This was therefore excluded It was certainly not a case of simple ascites, but was it a case of encysted dropsy, so called, of the peritoneum resulting from simple peritonitis? This is an extremely rare affection, and in the early stages there are symptoms of constitutional disturbance The abdomen is not prominent, and often it is flaccid Encysted dropsy was excluded

Finally, on June 20, I aspirated the cyst under antiseptic precautions The fluid which escaped was of a light straw-color, and coagulated as speedily as blood After aspiration, large masses were readily felt through the abdominal wall The character of the fluid corresponded with that which is said to characterize fibro cystic tumors of the uterus The speaker had, however, seen other cases which showed that the character of the fluid was not pathognomonic In one case of abdominal tumor, fluid was removed which did not coagulate even after being kept for many days The abdomen was subsequently opened and a fibro cystic tumor found In a case of supposed ascites in a man, aspiration was performed and the fluid coagulated quite rapidly After the cyst was aspirated the patient did well for three days, when acute peritonitis supervened, and the patient died on the seventh day

At the autopsy, a mass as large as a child's head was found in the abdomen This consisted of omentum, the transverse colon and small intestine, bound together by inflammatory exudation The inflamed peritoneum was invaded everywhere with miliary tubercles There was no ovarian or uterine disease There was some tubercular ulceration of the small intestine, the other abdominal organs were not affected The pleura was also invaded with scattered miliary tubercles In both lungs there were some tubercles

This, then, was a case of encysted tubercular peritonitis simulating ovarian or parovarian cyst The failure to recognize the true condition was ascribed to want of attention to the previous history of the case and the recognition of the fact that there had been free fluid in the peritoneal cavity at the first visit The speaker then referred to the few similar cases which had been recorded In these cases the disease has appeared, as a rule, under the age of twenty-five years It has progressed rapidly, the length of time varying from six weeks to eight months

Case 2 —F R, age 24, was admitted to the hospital in July, 1883 She claimed to belong to the colored race but looked much like a white woman She had been married one year, but had never been pregnant There was no evidence of uterine disease The abdomen was much enlarged, measuring forty-seven inches just below the umbilicus Vaginal examination showed the uterus pushed forward by a sac containing fluid There was apparently an immense unilocular sac This had been first noticed seven or eight years before The increase in size had been gradual and unaccompanied with pain As to diagnosis, ascites was dismissed both by the physical signs and the absence of any cause to account for such a condition The length of time which the affection had lasted was against its ovarian origin There are, however, exceptional cases in which an ovarian tumor may be present for a number of years, even as many as twenty-four, without requiring operation The length of time which the cyst had been present, the marked fluctuation, and the flaccid nature of the tumor were in favor of a parovarian cyst There was one point against this diagnosis, and that was that although the cyst was flaccid, it could not be compressed below the umbilicus Fibro cystic tumor was readily excluded The history of the case was against the existence of encysted peritonitis The balance of evidence seemed to be in favor of an ovarian or par ovarian cyst

On July 13 the operation was performed It was made largely with the view of exploration The peritoneum was found much thickened and closely adherent to the sac With difficulty the adhesions were separated for a short distance and the cyst presented the appearance of an ovarian cyst A trocar was introduced and forty pounds of a greenish, viscid fluid removed An endeavor was made to enucleate the cyst, but the adhesions were so extensive that this could not be accomplished The cyst was then incised to the extent of the abdominal opening, and in looking into it, it appeared to occupy the whole abdominal cavity, stretching tightly over the spinal column A small portion of the wall of the cyst was removed, a drainage-tube introduced and the opening closed with stitches Peritonitis ensued and the patient died A post-mortem was made, but owing to the doctor's unavoidable absence, was not sufficiently full to throw any more light upon the case than had been obtained at the operation The nature of the cyst therefore remained unsettled

Dr T A Emmet made a few remarks in regard to the difficulties of diagnosis It seemed to him that the older he became and the more experience he had, the more uncertain he was about diagnosis While yesterday he did not favor opening the abdomen, yet when a woman has an abdominal tumor, he favors opening the abdomen to make a diagnosis, because she has something which must come out Rapidity of development can not be depended on He had seen par-ovarian cysts develop in six weeks, and recover after operation He had also seen cases which lasted twenty-three years He had twice opened the abdomen expecting to find an ovarian cyst and had found a fibro cyst About two years ago he saw a case in which he could not make a diagnosis The abdomen was opened and he saw just such a cavity as had been described It seemed as though a cyst had at some time ruptured and its contents had become encysted The cavity was left open, frequently washing it out In six weeks the cavity had greatly diminished Unfortunately the patient died at this time from strangulation of the small intestine. There is no set of symptoms which belong exclusively to a certain condition.

DR. WILLIAM GOODELL, of Philadelphia, had removed tumors the nature of which he does not know to this day. In one case he worked for forty five minutes before he found out what the tumor was. It turned out to be two ovarian tumors which had coalesced, including the uterus between them. He felt more and more the necessity of performing the exploratory operation, for it is impossible to make a correct diagnosis in many of these cases. To illustrate the difficulties of diagnosis, he reported a case which he saw some time ago. A lady presented herself with a solid tumor of the abdomen. There was also metrorrhagia and menorrhagia. He diagnosed a fibroid tumor of the uterus, but the growth was so mobile as to suggest the possibility of a fibroid tumor of the ovary, and he so noted it in his record book. He advised against an operation. The lady went north, and her sufferings became so great that she consulted a distinguished gynecologist, desiring an operation. He wrote to Dr. Goodell, asking his diagnosis. The operation was performed, and a large fibroid of the ovary removed.

DR. T. A. REAMY, of Cincinnati, wished to put on record another case in which a fatal result followed aspiration in tubercular peritonitis. The patient was a man, but it presented all the characteristics of an ovarian cyst. The patient died the second day after the removal of the fluid. There is great difficulty in the diagnosis of these abdominal tumors. In reference to the coagulability of fluid from other sources than fibro cystic tumors of the uterus, he tapped a woman some years ago and obtained a large quantity of pure blood. This coagulated at once. The patient recovered and is still living. He inferred that this was a case of tumor of the omentum.

DR. HOWARD remarked that it was agreed by all that cases often occur in which the diagnosis can not be accurately determined, but in the majority of cases he thought a correct diagnosis was made. The fact that he was able in these two cases to eliminate so many of the ordinary conditions which give rise to these tumors, showed that the physician has the means of making the diagnosis. The object of the paper was to give an accurate account of this case, in order that it might assist others in cases of obscure abdominal tumors.

DR. E. W. JENKS, of Detroit, read a paper on

THE CARE OF THE PERINEUM DURING LABOR.

He referred to the various opinions which had been expressed on this subject. There is a general agreement as to the importance of preserving the perineum. In certain cases, however, from anatomical and pathological conditions, laceration is almost inevitable. He then referred to the various methods which had been proposed, dividing them into two general classes, those which aimed to support the perineum and those which were used with the object of retarding the progress of the head. There is one class, numerically small, who believe that the perineum should be let alone.

The method about to be described he had adopted several years ago and it had given him much satisfaction. He was persuaded that he had saved many perinei through its use. It was recommended for primiparæ and others where the structures were greatly imperilled. During the early part of the second stage the patient is allowed to assume any position she prefers, but when the head begins to distend the perineum, the patient is placed across the bed with the limbs in the lithotomy position, with the exception that the knees are kept close together. This is important. The limbs are held in this position by two assistants. A piece of muslin, or a towel, ten inches wide and forty or fifty inches long, is carried around the buttocks of the patient and over the hemisphere produced by the bulging perineum, with the upper edge on a level with the fourchette, and the ends given to the assistants. They are instructed to make traction during the pain in the manner that the accoucheur may direct. The bandage must be applied smoothly. The direction of the force may be made in any required direction. Care must, however, be taken that the pressure is equally distributed and that the assistants do not simply pull on the middle or posterior part of the bandage, while the anterior portion is left lax.

In order to show that this procedure was based on good anatomical grounds, the speaker next referred to the anatomy of the perineum, illustrating his remarks with diagrams. According to the old descriptions of the anatomy of this region, it was considered that the muscular fibres decussated in the part between the vagina and rectum. Recent observations show that this is not the case, but that the fibres simply meet and a laceration of the perineum divides the muscular fibres transversely, with the exception of those of the transverse perinei. The fibres are simply separated. When the sphincter ani is divided, its fibres are of course divided transversely. The perineum is prevented from laceration by the protection afforded by the tissue below and the integument. The bandage used in the way described affords a supplementary perineum, as it were. By keeping the limbs in the position indicated nature is able to supply tissue for the relaxation of the perineum. When the perineum is bulged the lateral and posterior sulci disappear, and the perineum, with the advancing head, forms almost a hemisphere. The towel is in contact with every part of this hemisphere. The advance of the head may be retarded by making traction on the towel. Where it is accessible, a narrow bed may be used with advantage, the assistants taking their position near the head of the patient.

The use of this bandage avoids any tendency to exciting expulsive efforts from reflex irritation of the perineum, as is sometimes seen where the fingers are used. It is comfortable to the patient and does not cause more exposure than other methods. The bandage may be kept on until the shoulder is delivered, thus avoiding rupture from this cause. In order that this method shall be successful, it is important that every detail shall be carried out with painstaking care. Should a rupture occur, the immediate operation should be resorted to.

(*To be concluded.*)

CHICAGO MEDICAL SOCIETY

Stated Meeting, Oct 5, 1885

The President, C T Parkes, M D,
in the Chair

Dr F E Waxham read a paper on

INTUBATION OF THE LARYNX, WITH A REPORT OF FIVE CASES

The paper was supplemental to one read before the Society on April 20th, in which the operation was minutely described Dr Waxham exhibited a larynx with the tube *in situ* He described the manner of performing the operation, as follows, by the nurse holding the child in her lap, with the hands at the side, an assistant firmly holding the head backward The mouth is held open by a gag placed on the left side between the teeth The tube, armed with a silk bridle, well waxed, is now secured to the introducing instrument The right hand manipulates the instrument, while the index finger of the left hand guides safely and quickly the tube over the epiglottis into the larynx, when the introducing instrument is removed and the tip of the finger presses the tube well down into the larynx We make sure the tube is in proper position by the easier breathing, the tube remaining stationary, and by coughing on the patient attempting to swallow water The bridle of silk is apt to produce violent coughing, and is generally removed The latest improvements in the tubes consist in an enlargement of the head of the tube with a backward curve, preventing the tube from slipping into the trachea and allowing the epiglottis to fall during the act of deglutition There is also an enlargement in the center of the tube, allowing it to be more easily extracted Dr Waxham reported in detail five cases of croup treated by intubation One case recovered, one died six days after intubation from pneumonia, the result of unfavorable surroundings The other cases were not such that recovery could be definitely expected Dr Waxham then presented the history of the five cases in detail after which Dr H T Byford opened the discussion by saying he had the pleasure of seeing the case reported in which there was a complete recovery In the contrast between this operation and tracheotomy there are many points in favor of intubation, and there are not many cases in which tracheotomy is indicated that intubation is not, one of its chief advantages being its simplicity The first case of tracheotomy he had ever performed was a success and gave him a great deal of encouragement, but the next was such a terrible case, and a failure, that he was discouraged He had assisted at several tracheotomies, but the difficulties of the operation, the trouble of overcoming the prejudice of the parents against the operation, and the difficulties and bad results following had caused him to *abandon the operation as of little use except in good cases But when he saw this case, with all the absence of numerous attendants and paraphernalia* in the after treatment, and the comfort and freedom of the patient, he was greatly astonished The simplicity and safety of the operation and the comfort afterwards, the fact that the consent of the parents can be easily and early obtained, that failure to relieve will not bring discredit upon the physician, and that the tube opens in the throat instead of the external air, leaves no doubt in his mind that intubation, whenever it can be successfully accomplished, will supersede tracheotomy in private practice

Dr W E Casselberry said he was in constant attendance on one of the cases which terminated unfavorably, but the effect from the operation was such as to convince him of its utility in many cases In this case the former physicians in attendance had thought the patient had recovered from diphtheria, but the membrane later invaded the trachea The young child was *in extremis mortis* and it was decided tracheotomy would be of no avail, and it was not thought intubation would be much better, but in order to give the child a chance it was done The child lived twenty four hours, and its last hours were comparatively comfortable In this case there was considerable difficulty in the introduction of the tube, and it was a lesson to him that practice in introducing the tube on the cadaver might obviate many difficulties in introducing it on the living subject In the case of this young child, the tube attached to the instrument for introducing it made too short an angle to be easily introduced The idea suggested itself to have a joint in the introducing instrument so as to be able to easily pass the curve of the pharynx The tube caused no cough or difficulty in swallowing, and was easily withdrawn A German physician lately states that in 111 cases of tracheotomy under his control, sixty-three recovered, and an American physician notes twenty cases, of which nine recovered It seems from these statistics that tracheotomy is not to be discarded, but we nevertheless will find a large field for intubation of the larynx Intubation will be preferable in young children not apt to recover from tracheotomy, in diphtheritic cases, and in cases when the friends object to tracheotomy

Dr R G Bogue said I have happened to have something to do with tracheotomy While there are a great many inconveniences attending the operation and the care of the patients, subsequently, there certainly has been a good deal to commend in its performance in many cases The number of recoveries after tracheotomy are not few The gentleman preceding me referred to statistics showing a larger percentage of recoveries than I had happened to know But those who have operated a goodly number of times have good reason, from its success, to resort to it in many cases Intubation is a simple operation compared with tracheotomy, and will recommend itself in many ways, and if it proves to be of equal success in saving life, it should be used in preference to tracheotomy Many reasons arise why it should be used It is not a formidable operation, parents' consent to it can be easily obtained, and the relief obtained by intubation seems as great as in tracheotomy After each tracheotomy there is a period of rest and quiet and apparent promise of success, for a period of twenty-four to thirty-six hours, then an extension of the disease into the deeper air passages, or some complication destroys the life of the patient. The benefit of intubation with only this alleviation is apparent. It is to be hoped after a more extended trial it will prove to be of as much, if not more, service than tracheotomy, and it will commend itself to the profession.

Dr. G. C. Paoli said that Dieffenbach was the first to use intubation in diphtheria and croup, and a Parisian physician tried it at the time, each without the knowledge of the other's experiments. Dieffenbach used an india rubber tube, but he as well as the Parisian physician abandoned intubation. This is a different method, it is true, but it can never be recommended until we have statistics from those having great experience, in hospitals especially, to prove it preferable to tracheotomy.

Dr. D. W. Graham commended the report as being an effort in the right direction. It shows that intubation has some merit, as a means of treating obstruction of the larynx, and that it is destined to become at least a partial substitute for tracheotomy in diphtheritic croup. From a theoretical standpoint it would seem that there would be some liability of these tubes causing œdema of the larynx, if retained in place any length of time, on account of the mechanical pressure on the veins of the mucous membrane. Future observation will show whether they are entirely harmless. However, there does not appear to have been any trouble in this respect in the cases reported.

If this method should become established and recognised, as it now promises, it would and ought to be counted as a new procedure, notwithstanding what Dr. Paoli has said about the efforts of the older surgeons to put the same idea into practice, for whatever has been attempted heretofore in this direction has proved fruitless.

Dr. Waxham, in closing the discussion, in answer to various questions, said the longest time the tube was worn continuously was six days. Dr. O'Dwyer reports two cases, terminating favorably, in which the tubes had been worn ten days. He never found any œdema of the larynx caused by the wearing of the tube. In very young children it is necessary to remove and cleanse the tube. Older children, if not exhausted by disease, will expectorate freely. The previous attempts at intubation in France were not successful, but they were not according to the methods now employed. Trousseau discouraged intubation, and thus French physicians were influenced against it. The tubes must be thin, but their weight is unimportant. He had never found it necessary to use cocaine in introducing the tube, as this operation is generally easily and quickly done.

FOREIGN CORRESPONDENCE

LETTER FROM LONDON

(FROM OUR OWN CORRESPONDENT.)

Digital Tenotomy for Pianists—The Lemon Treatment of Bilious Fever—The Death-rate—Ancient Anæsthetics—Prof. Huxley—Hospitals in London—Anisic Acid, the New Antipyretic.

Attention is again being called, by a well known medical man, to the benefit to be derived by those who practice frequently on the piano, harp and stringed instruments generally, by submitting to a surgical operation which consists in dividing the tendons of the ring finger. Pianists are aware that out of the five fingers composing the hand, the fourth one, as it is termed, is the most rebellious in action, being alike the weakest and least flexible of all the others. This feebleness proceeds from the lateral tendons that join the ring to the other fingers, and in a measure paralyze its movements. The operation is simply that of tenotomy. The finger becomes as free as the others, and can work upon the key board or music strings with equal force and facility.

The lemon treatment of biliousness is quite fashionable at present. Most people know the benefit of lemonade before breakfast, but few know that it is more than doubled by taking another at night also. The way to get the better of the bilious system without blue pills and other drugs, is to take the juice of one, two or three lemons, as appetite craves, in as much iced water as makes it pleasant to drink without sugar, before going to bed. In the morning on rising, at least half an hour before breakfast, take the juice of one lemon in a goblet of water. People must not irritate the stomach by eating lemons clear, but diluted properly, so that it does not irritate the throat, and taken on an empty stomach, the improvement is marked.

The following results in the reduction of the death rate are eminently satisfactory, and justify confident anticipations that, by a steady perseverance in dealing with all questions relating to sanitation, the time will soon arrive when we shall have outdistanced all our ancient predecessors, to the great moral and material welfare of the community and the comfort and happiness of all classes of the people. Civil registration was first established in 1838, and the mean annual death rate of England and Wales for the thirty eight years (1838 to 1875 inclusive) was 22·30 per 1000, the mean annual rate for the first eighteen years being 22·42, and for the last twenty years 22·19, an improvement of only ·23. The mean annual rate for the eight years, 1876–1883, both inclusive, was 20·26, the difference between the mean annual rate for the years 1856 to 1875, and 1876 to 1883, showing an improvement of 1·93 per 1000, or an apparent saving of 49,320 lives annually, although as the age distribution of the population has been altered, the number of lives actually saved would be somewhat less. Besides the diminished mortality, it must be remembered that preventable sickness bears a regular proportion to preventable deaths, and if this be estimated at the low proportion of twenty five cases to each death, we get upwards of 1,000,000 cases of sickness annually prevented in the period from 1876 to 1883 had the death rate remained stationary and not decreased in the way mentioned.

Sir Henry Thompson declares there is no foundation whatever for the common notion that a fish diet tends specially to feed the brain. He says, however, that fish is particularly suitable for persons who are unable to take much exercise.

An interesting paper has just been published upon ancient anæsthetics. Abelard, speaking of the creation of Eve from a rib of Adam, speaks of the deep sleep which fell upon the latter as similar to that which physicians produce in patients upon whom they wish to operate. Pliny speaks of a stone of Memphis which, when crushed and treated with vinegar, renders any part to which it is applied insensible to pain, and many old authors speak of surgeons producing sleep in their patients before an operation, by mixing with their food a decoction of the leaves of the root of the mandragora, or some grains of the plant called "morion." Preparations of these two plants, as well as of other narcotics, were employed by surgeons down to the thirteenth and fourteenth centuries, but much less in subsequent times. Opium was also used for a similar purpose, while in the East the anæsthetic properties of hemp have been known from the earliest times. These were all taken into the stomach, but anæsthesia by inhalation was also known. Two different preparations were discovered in the thirteenth century, one by a Dominican of Rome, the other by a surgeon named Theodoric, who was also a preaching friar, and subsequently a bishop. Both of these were prepared from opium, henbane, mandragora, hemlock, and many other plants, and were inhaled from a sponge. It is, however, difficult to believe that preparations so little volatile could produce anæsthesia by simple inhalation. Mons. Perrin, who has studied ancient anæsthetics, has given the composition of a liquid which contained all the ingredients required for chloroform, and it is said that this was applied to witnesses or prisoners who were about to be tortured in the judicial tribunals of the Middle Ages. After inhaling it, the unfortunate subject was plunged into a semi-comatose state, which diminished in a certain degree the pain of the torture. This liquid was always kept in a place adjoining the torture-chamber. Dr. Simpson has the reputation of having been the discoverer of anæsthesia like Dr. Harvey, the reputed discoverer of the circulation of the blood, they were really the men who brought the discoveries practically into use, and pointed out to us clearly and truthfully the *modus operandi* of the circulation and anæsthesia.

It is stated that Professor Huxley is about to retire from his various appointments under Government with a pension of £1,200 a year.

From a recent estimate it appears there are in London sixty-seven hospitals of all kinds. They afford accommodation in beds for 6,588 patients, and on an average 56,493 in-patients occupy these beds annually. The same hospitals make medical provision for out-patients, and 530,564 out-patients are also received. At the present time, many of the London hospitals are financially in a bad way on account of the present great fall in the revenue obtainable from their landed investments. Many have had to close some of their beds, and are now making earnest appeals for funds.

It is stated that a new antipyretic remedy known as anisic acid, formed by the oxidation of oil of anise, closely resembles salicylic acid in its effects.

G. O. M.

LETTER FROM PARIS.

(FROM OUR OWN CORRESPONDENT.)

Ptomaines in Cholera dejecta—Influence of Solar Light on the Bacillus Anthracis and on Vegetation—Prehistoric Skulls at Grenoble—Artificial Fecundation—Two Cases of Hydrophobia.

In a work published last year by M. Gabriel Pouchet, he established the existence of an alkaloidic substance in the dejections of choleraic patients, which was very decomposable and behaved in the manner of a violent poison as regards man and animals. It was interesting to determine, in view of the pathology, the mode of production as well as the rôle of this substance in choleraic manifestations. To enable him to do so, M. Pouchet analyzed broths containing pure cultures of the microbe of Koch, and he was able to establish the presence, though in traces only, of an alkaloid liquid the exterior characters of which (odor, decomposability, toxicity for animals) appeared identical with those of the substance isolated from choleraic dejections. If these results be confirmed the microbe of Koch will really be the pathogenic agent of cholera.

About six months ago M. Arloing addressed to the Academy of Sciences a note relating to the influence which artificial light would exercise on vegetation and the properties of the "bacillus anthracis." At the meeting of the Academy last week M. Arloing gave an account of the results of analogous experiments performed by him with solar light. These results corroborate those obtained with artificial light. Gas light retards the vegetation of the bacillus anthracis. Sun light, in the month of July, destroyed in two hours the vegetative power of the spores of the charbonous bacillus. These facts would not only demonstrate the destructive power of the sun as regards pathogenic germs, but they would add to others already known, to show that the spore is not so resistant as one would be led to believe, and that the attempts at the attenuation of the different viruses in this state are perfectly legitimate.

At the meeting of the Academy of Sciences of last week, M. Arloing submitted another note on the influence of the sun on vegetation, and on the "vegetability" of the virulence of cultures of the bacillus anthracis. In this second note the author makes out that solar light attenuates the virulence of cultures of this bacillus and transforms them into a series of vaccines as surely as heat. Whether the attenuation thus obtained will have the property of self-preservation and of being transmitted by means of generation is a question that M. Arloing intends undertaking to solve. If positive results are obtained vaccines may be prepared during the summer season. Be this as it may, these facts demonstrate that light is a biological agent very important in the world of the infinitely small.

At the last annual meeting of the French Association for the Advancement of Science, which was held at Grenoble, M. Manouvrier made some remarks on the skulls at the museum of that town. The author observed that among the prehistoric skulls found in the grottos of La Buisse and Balmes, three belonging to the bro-magnon type, and two of the type of the Savoyards of the present day This fact tends to demonstrate that from the Robenhausian period, the Savoyard races and those of bro magnon lived side by side in the environs of Grenoble Among the modern skulls to be seen at the museum, there is one of a child which presents a great many points of interest

1 The sagittal suture is completely synostosed from which ordinarily results scaphocephaly but this deformity, which is the consequence of the ulterior growth of the skull in the only direction of its length, had not the time to be produced

2 The superior half of the left coronal suture is equally synostosed From this results an arrest of development of the corresponding region with compensatory arching of the opposite side and prominence of the right frontal protuberance This variety of deformity belongs to the type described by M Manouvrier under the name of "reniform deformity" The difference consists simply in that the synostosis took place, in this case, at the superior portion of the coronal suture, whereas ordinarily it occurs in the inferior portion The deformity which results from this is therefore somewhat modified, which renders this deformity still more instructive

On the 28th of July last, a candidate for the doctorate submitted his thesis to the Paris Faculty of Medicine, entitled "Contribution to the History of Artificial Fecundation" The thesis was rejected, and the examination put off in consequence, much to the astonishment of the candidate and of his friends, as the subject had been treated of in scientific works, and it formed the title of a thesis submitted not long ago at the same Faculty by Dr F Gigon, who obtained his degree without opposition The public newspapers then took up the matter, and as usual published sensational articles for and against the decision of the Examining Board, some declaring that the thesis in question was rejected as being considered immoral Prof Pajot, President of the Board, in a letter published in the *Revue Scientifique*, repudiated the assertion, and stated that the thesis was rejected on account of the subject matter in it having been treated of in a rather unscientific manner A writer commenting on this subject in the same periodical, says that artificial fecundation is an operation that may raise some respectable scruples, the indications of which are exceptional, but which ought to be regarded as one of the greatest conquests of science Already proposed by Hunter, it penetrated, with difficulty, it is true, into medical practice, but now it is taught at the Faculty and described in the most recent treatises on obstetrics and gynæcology, as may be verified in reading over the works of Professors Pajot and Tarnier

About a week ago two children were taken to the hospital at Versailles with symptoms of rabies, to which they both succumbed in the space of a few hours The interesting point in this case is Some years ago both these children, the one a boy aged 11 years, and the other a girl, his sister, aged 15, were bitten by a mad dog, which was immediately killed The wounds caused by the bites were cauterized and nothing more was thought of the cases, when the day before their admission to the hospital they were suddenly seized, at an interval between them of half an hour, with symptoms of hydrophobia, from which they both died within a few hours of each other This example is one of the most remarkable on record, but I think it a pity that the published report does not mention the precise number of years that intervened between the accident and the appearance of the symptoms above referred to, as we should then be in a position to know the exact length of time of incubation

Apropos of hydrophobia, I may mention that M Pasteur is continuing with great perseverence, at Arbois, his retreat in the Jura, his experiments with the view of ensuring to animals exemption from hydrophobia He intends putting his method in practice on his return to Paris, as he is confident that it will also prove efficacious in man Before his departure for Arbois, M Pasteur had under treatment a little boy of nine years of age, brought by his parents from Alsace, where he had been bitten in the haunches, on both legs, and in the hand This child was taken direct to M Pasteur, who, for the first time, applied his method, but whether it be successful or not remains to be seen The accident occurred about three weeks ago A B

DOMESTIC CORRESPONDENCE

LETTER FROM PHILADELPHIA

(FROM OUR OWN CORRESPONDENT)

The International Medical Congress—Dr Shakespeare to go to Spain to Investigate the Cholera—Dr Hamilton's Retention as Surgeon-General of the Marine Hospital Service—The Veterinary Department of the University of Pennsylvania —A good Opening for Young Men

The questions in regard to the proposed meeting of the International Medical Congress, which were the subject of so much discussion when I last wrote, have ceased to be a live issue in this city The action of the New Committee in New York seems to leave nothing to be done but to wait and see whether the European men will come to America under the circumstances or not It is believed here that they will not, at least not in sufficient numbers, to give the meeting an international character It is also thought by some, and hoped by others, who did not approve of all the acts of the Original Committee, that those who have charge of the interests of the Congress in Europe will decide to hold the next meeting in some city there—Berlin is spoken of as most likely This, as one of the most conservative men in this city said to me a few days ago, would be the simplest way out of an awkward dilemma, and would furnish an opportunity for the present excitement of feeling to subside to the advantage of all concerned

I have heard some comment upon the action of the New Executive Committee in New York, on Sept 24, whereby they unanimously resolved that what they were to do was not subject to "revision, amendment or alteration" by the General Committee, which appointed them, or even by the American Medical Association itself It is wondered here whether such a declaration of independence will be tolerated by the Association, when it meets in St Louis, or whether it will send the Committee out to read and reflect upon the opinion of Mr Randall with which their predecessors were put to naught Time alone can show, but the members of the Original Committee are said to feel a keen regret that they did not at the start adopt this easy method "to prevent all further misunderstanding, both at home and abroad "

Perhaps I ought to say a word in regard to the statement which was made in a recent letter to the JOURNAL, by one who wrote from Philadelphia and signed himself "W H P ," that the sentiment of the profession in this city was not correctly represented in my last letter The only reply to this intimation which is called for at present, is to direct the attention of your readers to the significant fact, that the assertion that a considerable number of respected men in this city were of a different way of thinking has not been backed up by the publication of their names If any one who thinks I have misrepresented the sentiment of this city will publish a list of these who agree with him, I think it will only be necessary to place it alongside of the list which I gave long ago, in order to show that what I said was exactly so And I think it will be better for even those who most disapprove of what was done here about the time of my last writing, to hear the plain truth, whether they like it or not, than that they should be misled with flattering pretences

The colleges have now begun their winter sessions, with the prospect of good classes The societies are at work, and I shall soon have pleasant and interesting subjects to write about Already the Pathological Society has had a feather put in its cap by the selection of its president, by President Cleveland, to go to Spain, as the representative of the United States, in investigating the cholera Dr Shakespeare, who is well known as a student of micology, and as a friend and advocate of Koch in this country, has been chosen to investigate the scientific questions raised by the present epidemic of cholera in Europe, and to learn whether any new measures are needed to properly protect this country from its advent here, and whether the present quarantine regulations can be modified with advantage As Dr Shakespeare is a firm believer in the "comma bacillus," it may be relied upon that he will find it if it is to be found in Spain, and the opportunity he is to enjoy of studying cholera on the spot may be regarded as a singularly fortunate, one for him, as it is to be hoped it will prove fortunate for science

It has been with great satisfaction that the professional friends of Dr Hamilton, Surgeon-General of the Marine Hospital Service, have learned that the President of the United States has stepped between him and those who were attempting to displace him from the position which he has heretofore filled so creditably The ground of the President's interference being that Dr Hamilton has fulfiled his duties with zeal and discretion, and with a strict regard for the public interests, is not only a well deserved testimony to Dr Hamilton's faithfulness, but also a cheering evidence of the President's determination to free the medical service of the army and navy from the debauching taint of practical politics When this is connected with his strong wish, which unfortunately cannot be fulfiled, that Prof Agassiz should take the head of the Coast Survey, it seems that we have a President who has a higher idea of the interests of science than to make it a cat's paw to politics

The Veterinary Department of the University of Pennsylvania is now fully opened It has been organized at an expense of about fifty thousand dollars, with Dr Huidekoper, who studied veterinary medicine in Europe, after having graduated in medicine in the University some years before, at its head The buildings now completed are extensive and well suited to their object They are of stone and brick, and extend for more than four hundred feet along Pine street, which passes through the grounds of the University They contain stalls, sweat-baths, foot-baths, a padded cell for lunatic horses, an armory for instruments, forges, lecture rooms, working laboratories, dissecting room, and in fact, everything necessary for studying the diseases of the lower animals under the most favorable circumstances A large part of the building is to be used as a hospital for sick or injured horses, cattle, sheep, dogs, cats, etc

It is hoped that the attention to be given to the study of veterinary medicine in this department of the University, will lead to an advance in the position which this art shall occupy in this country In Europe there are a number of men of high scientific attainments who are veterinarians, and their contributions to the art of healing have a much wider range than that of the class which is especially the object of their study There is no reason why the study of comparative medicine should not receive a new impetus from the association of this new department with the others already existing in the University It is to be hoped also, that the study of veterinary medicine under these auspices, will attract a class of men who are capable of elevating the pursuit to which they are to devote themselves above the level which it has hitherto occupied in this country It is a calling which stands in need of men who will consider it honorable and help to make it so To young men with zeal and perseverance it offers a most promising field of scientific study, as well as an unusually certain road toward a good income It would probably be good for both man and beast, if some of the young men who are now thinking about studying medicine would make up their minds to study animal medicine, in which they would have a clearer field to themselves, and leave a little clearer field to those who are now trying to make a living out of their fellow men

C W D

THE INTERNATIONAL MEDICAL CONGRESS

To the Editor of the Journal

Dear Sir — 'An Old Member of the Medical Profession," in his letter to the JOURNAL of September 19, has sounded a key-note by quoting that part of Dr Flint's "Presidential Address" in Washington in which he urged the American Medical Association, as the only proper representative body of the profession in this country, to invite the International Medical Congress to hold its next meeting in this country

The animus of certain medical journals, among which may be particularly mentioned the *Medical News,* is shown more clearly since the Committee met in New York, on September 3 and 4 In the issue of the *Medical News,* of September 19, is a garbled report of the meeting of the Committee in New York By comparing the report of the Committee as published in the JOURNAL of September 12, and the *News,* of September 19, the conclusion is irresistible that the report has been maliciously garbled and falsified by the *News,* since two Sections are entirely unnoticed by that *representative* of professional purity Again, it may be seen that the Committee only reported, in the list of officers of Sections, the Chairmen of Sections, but the *News* gives a full list, save in the Section on Obstetrics, and *then quotes the following* "Lists of Vice Presidents, Secretaries, and Councilmen for each Section were named by the Committee of Arrangements, but as it was not practicable to ascertain at once who would accept the places assigned to them, or who of those who had been announced in the medical press as declining to accept positions before the present rules and organization had been adopted, as given heretofore, might wish to withdraw such declination, the *final adjustment of these offices was referred* to the Executive Committee of the Congress,[1]" etc

With the exception of the clause just quoted and Rule 1, not a single rule or regulation adopted by the Committee is given or even referred to Perhaps it was scarcely to be supposed that the *News* would comment on or quote the following "It was decided that no person should occupy more than one position in the organization of the Congress" But in view of the fact that this was a part of the report of the Committee, the animus of the *News* will be apparent when we read *its* list and see the same name (in several instances) in more than one position It would be charitable to suppose that the editor of the *News* did not read the full report of the Committee, as published in the JOURNAL of September 12, but this is scarcely credible

Instead of publishing a long list of names, uselessly, as it did, why did not the *News* give the full report of the Committee to its readers? Was it for want of space? The full report would have occupied no more space than the meaningless list which was published Space was not wanting to publish quotations from other journals, at least one of which was published long before the Committee met in New York, another from a recently acquired "New Code" ally, another from a journal which persistently misuses the English language in saying that the invitation to the Congress was not from the American Medical Association, and still another to the effect that "*The Kansas City Medical Record* offers to pay a liberal reward for a germicide that will destroy the microbes that were instrumental in ruining the International Medical Congress and weakening the vitality of the American Medical Association by their onslaught at New Orleans" Had the *Kansas City Medical Record* offered a reward for the microscopic fungi that *attempted* to ruin the International Congress, it need only have applied to the owners of the *Medical News,* seeing that the desired germs are on the salary list of that firm The germicide which would most effectually kill these microbes would be the erasure of their names from that salary list

Finally, evidence is abundant that resignations have been obtained by certain members of the Original Committee (now resigned) solely by misrepresentations, evidence can be produced that the resolution passed in Washington in 1884 giving *existence* to that Committee, was written by a member of the Committee, and that it was the intention so to word it as to take the whole matter out of the hands of the Association, it can be shown that the distribution of at least some of the offices under the Original Committee was done by *one member* of that Committee, without consultation with the others, and it is true and can be proved that a member of that Committee has used every endeavor, and misrepresented facts in order to obtain resignations from the Organization of the Congress, after having given a solemn promise that he would aid the New Committee in every way possible Does the profession of America need anything more to show the animus of certain men who would rule or ruin? Does it need further proof that these are *not* the men who should properly represent the profession of the United States?

AN OUTSIDER

Chicago, October, 1885

[1] Italics mine

ASSOCIATION ITEMS

INFORMATION OF IMPORTANCE TO ALL MEMBERS OF THE AMERICAN MEDICAL ASSOCIATION

MEMBERSHIP —Every one who attends an annual meeting of the Association as a delegate pays at that time five dollars, and thenceforward becomes a Permanent Member He continues as such as long as he remains in good standing in the body from which he was originally sent as a delegate As a Permanent Member, he must pay *Five Dollars Annually,* when notified by the Treasurer, whether he attends the meetings of the Association or not Payment of annual dues entitles him to receive the weekly JOURNAL of the Association for one year

MEMBERS BY APPLICATION are such as have not become Permanent Members in the manner above indicated, but apply to the Treasurer for membership, forwarding at the same time to him five dollars and the certificate of the President and Secretary of their State or local society, that they are in good standing in such society They pay five dollars annually thereafter, when notified by the Treasurer Members by application can join the Association at any time, and they receive regularly the weekly JOURNAL

WHEN DUES ARE PAYABLE —The annual dues from Permanent Members are payable to the Treasurer at the time of the annual meeting of the Association, or immediately thereafter. The payment entitles the member to receive the JOURNAL for one year from the following July. Payment for 1885, for example, entitles the member to the JOURNAL from July, 1885, to June, 1886, inclusive.

As some of the members have not yet forwarded to the Treasurer their dues for 1885, they are urgently requested to do so at an early day. Having entered upon another year of membership, they are morally and legally responsible to the Association for the payment of their annual dues, having already received for three months of the new year—1885—the JOURNAL of the Association.

SUBSCRIPTIONS TO THE JOURNAL, from those who are not members of the Association, should be forwarded to the office of publication, 65 Randolph Street, Chicago, and not to the Treasurer; but *all payments of annual dues must be forwarded to the Treasurer, Lock Box 1274, Philadelphia.*

DEATHS.—When a member of the Association, who is in regular receipt of the JOURNAL, dies, his family or other representatives are requested to inform the Treasurer at once of the fact.

PAYMENT OF DUES FOR PREVIOUS YEARS.—As a few members of the Association are still in arrears for payment of dues for 1883 and 1884, they are requested to forward at once to the Treasurer the amounts for which they are indebted to the Association.

TRANSACTIONS OF THE ASSOCIATION.—These annual volumes, thirty-three in number, to 1882 inclusive, may still be obtained, with few exceptions, from the Treasurer, at reduced prices. The Index to these volumes will be forwarded on receipt of *One Dollar*. An opportunity is thus afforded to complete sets of these valuable publications, or to obtain important papers and works which are daily becoming scarce.

RICHARD J. DUNGLISON, M.D., *Treasurer*.
Lock Box 1274, Philadelphia, Pa.

NINTH INTERNATIONAL MEDICAL CONGRESS, WASHINGTON, D. C., 1887.

[The following are some of the more important Rules adopted relating to the preliminary organization of the Congress.—ED.]

1. The Congress shall consist of members of the regular profession of medicine, who shall have inscribed their names on the register and shall have taken out their tickets of admission; and of such other scientific men as the Executive Committee of the Congress may see fit to admit.

2. The dues for members of the Congress shall be ten dollars each for members residing in the United States.

There shall be no dues for members residing in foreign countries.

Each member of the Congress shall be entitled to receive a copy of the "Transactions" for 1887.

3. The Congress shall be divided as follows, into seventeen Sections:

I. General Medicine.
II. General Surgery.
III. Military and Naval Surgery.
IV. Obstetrics.
V. Gynæcology.
VI. Therapeutics and Materia Medica.
VII. Anatomy.
VIII. Physiology.
IX. Pathology.
X. Diseases of Children.
XI. Ophthalmology.
XII. Otology and Laryngology.
XIII. Dermatology and Syphilis.
XIV. Public and International Hygiene.
XV. Collective Investigation, Nomenclature, Vital Statistics, and Climatology.
XVI. Psychological Medicine and Diseases of the Nervous System.
XVII. Dental and Oral Surgery.

4. The General Meetings of the Congress shall be for the transaction of business and for addresses and communications of general scientific interest.

* * * * * * * *

8. The official languages of the Congress shall be English, French, and German.

In the meetings of the Sections, no member shall be allowed to speak for more than ten minutes, with the exceptions of the readers of papers and those who introduce subjects for discussion, who may each occupy twenty minutes.

9. The rules and programmes shall be published in English, French, and German.

Each paper and address shall be printed in the "Transactions" in the language in which it was presented, and preliminary abstracts of papers and addresses also shall be printed, each in the language in which it is to be delivered.

All discussions shall be printed in English.

10. The President of the Congress, the Secretary-General, the Treasurer, the Chairman of the Finance Committee, and the Presidents of the Sections, shall together constitute an Executive Committee of the Congress, which Committee shall direct the business of the Congress, shall authorize all expenditures for the immediate purposes of the Congress, shall supervise and audit the accounts of the Treasurer, and shall fill all vacancies in the offices of the Congress and of the Sections. This Committee shall have power to add to its membership, but the total number of members shall not exceed thirty. A number equal to one-third of the members of the Committee shall constitute a quorum for the transaction of business.

11. The Officers of the Congress shall be a President, Vice-Presidents, a Secretary-General, four Associate Secretaries, one of whom shall be the French Secretary, and one of whom shall be the German Secretary, a Treasurer, and the Chairman of the Finance Committee.

12. The officers of each Section shall be a President, Vice-Presidents, Secretaries, and a Council.

13. The officers of the Congress and the officers of the Sections shall be nominated to the Congress at the opening of its first session.

MISCELLANEOUS

Health in Michigan —Reports to the State Board of Health, Lansing, by observers in different parts of the State, show that for the month of September, 1885 compared with the preceding month, the reports indicate that influenza, typho malarial fever, bronchitis and neuralgia have increased, and that cholera morbus, cholera infantum and diarrhœa have decreased in prevalence Compared with the average for the month of September in the seven years, 1879–1885, intermittent fever, remittent fever, dysentery, typho malarial fever, cholera infantum, cholera morbus, diarrhœa, consumption of lungs, and typhoid fever were less prevalent in September, 1885 For the month of September, 1885, compared with the average of corresponding months for the seven years, 1879–1885, the temperature was lower, the absolute humidity and the day ozone were about the same, and the relative humidity and the night ozone were more

New York State Medical Association —The second annual meeting of this Association will be held in the Murray Hill Hotel, New York City, on November 17, 18 and 19, and at the Carnegie Laboratory on the 20th, 1885 A full and very interesting programme of work is arranged for the four days, with the prospect of a large and profitable meeting John P Gray, M D, of Utica, is President, Caleb Green, M D, of Homer N Y, Recording Secretary, and E D Ferguson, M D, of Troy, N Y, Corresponding Secretary

Lead Poisoning at Sea —The Paris Municipal Laboratory has received a report concerning an epidemic of lead-poisoning which recently happened on a Norwegian vessel coming from Cadiz Several of the crew exhibited symptoms of lead poisoning, and the vessel was put into port in New York The captain and several of his men were sent to the hospital at Coney Island Two men died, the others recovered, after suffering severely The affair was investigated, and it was ascertained that impure drinking-water was the cause of the catastrophe The ship's tank was painted inside with red lead, the water became of a yellowish color The Municipal Laboratory has issued a recommendation to landlords and all persons who have cisterns or water reservoirs that resin or tar, dissolved in turpentine or benzine, should be used for painting them It appears that, in Paris and its suburbs, a great many cisterns are painted with pigment containing lead —*Brit Med Journ*, Oct 10, 1885

To Oculists and Publishers —Having taken charge of reporting for the *Revue Generale d' Ophthalmologie*, edited by Dr E Meyer, of Paris, and Dr Dor, of Lyons, on the progress of ophthalmology in our country, I beg leave to request all authors and publishers of ophthalmic works and papers to send me copies or reprints of their publications, in order to enable me to give the most complete review of the current ophthalmic literature of our country in a periodical of the largest circulation among our profession

Dr M Landesberg

40 W. 34th St, New York

Professor Haeser, senior member of the medical faculty of Breslau, has recently died, aged 72 His best known work is a History of Medicine, which was received with great favor, both in Germany and abroad

Charles Robin, the eminent histologist, died of apoplexy, on October 6, at the age of 64 Since 1852 he had been Professor of Histology at the Faculté de Médecine, of Paris He was made Member of the Institute in 1866

Dr O D Norton, Jr, has received the appointment of Acting Assistant Surgeon in the U S Navy, and is on the U S Steamer Minnesota, Station E, New York

Gazette de Gynecologie is the title of a new medical monthly, under the editorship of Dr D Ménière, of Angers It is published by O Doin, of Paris

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT U S ARMY, FROM OCTOBER 10, 1885 TO OCTOBER 16 1885

Lieut Col B J D Irwin, Asst Medical Purveyor, ordered from Dept Ariz to New York City, for temporary duty in charge of medical purveying depot at that place, relieving Captain Henry Johnson, medical storekeeper (S O 233, A G O, Oct 10, 1885)

Capt Geo W Adair, Asst Surgeon, leave of absence extended one month (S O 232, A G O, Oct 9, 1885)

First Lieut Edward R Morris, Asst Surgeon (recently appointed), ordered for duty in Dept Mo (S O 233, A G O, Oct 10, 1885)

OFFICIAL LIST OF CHANGES IN THE MEDICAL CORPS OF THE U S NAVY DURING THE WEEK ENDING OCTOBER 17 1885

L B Baldwin, P A Surgeon, detached from Naval Hospital, Philadelphia, and ordered to Navy Yard, Mare Island

D Dickinson, Surgeon, detached from Naval Hospital, Mare Island, and ordered to Training Ship "Portsmouth" as relief to Surgeon A M Moore

A M Moore, Surgeon, detached from Training Ship 'Portsmouth and wait orders

Joseph Shafer, Asst Surgeon, detached from Receiving Ship "St Louis" and ordered to Naval Hospital, Philadelphia, as relief of P A Surgeon Baldwin

Asst Surgeon F A Hester, detached from U S Str "Minnesota" and ordered to the "Tennessee," as relief of P A Surgeon Nelson H Drake

Nelson H Drake, Surgeon, detached from the "Tennessee" 31st inst, and wait orders

OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF MEDICAL OFFICERS OF THE U S MARINE HOSPITAL SERVICE FOR THE WEEK ENDED OCTOBER 10 1885

Bailhache, P H, Surgeon, to proceed to Tuckerton, N J, as inspector Oct 7, 1885

Austin, H W, Surgeon, to proceed to Albany, N Y, on special duty Oct 10, 1884

Gassaway, J M, Surgeon, to examine surfmen at Ellsworth, Maine, and other ports of First District, Life Saving Service Oct 9, 1885

THE USE OF THE OPHTHALMOSCOPE IN THE DIAGNOSIS OF BRAIN DISEASE[1]

BY W FRANKLIN COLEMAN, M D, M R C S, ENG

FORMERLY SURGEON TO THE EYE AND EAR DEPARTMENT OF THE ST JOHN (CANADA) PUBLIC HOSPITAL AND PROFESSOR OF DISEASES OF THE EYE AND EAR AT THE BALTIMORE POLYCLINIC AND POST GRADUATE MEDICAL SCHOOL

Our knowledge of the physiology and pathology of the central nervous system is so limited, the diagnosis of brain lesions so difficult, the well known conditions of the eye in those lesions so unmentioned or dubiously mentioned by the text books on medicine, as to afford me some excuse for urging the claims of the ophthalmoscope in the study of the intra ocular end of a brain nerve, during its structural changes which are connected with intra cranial disease As the subject embraces a limited personal experience, I freely admit the testimony of such authorities as Drs Allbut, Jackson, Gowers, and incidentally many others

While the nature of many diseases within the chest and abdomen is revealed to touch and the ear, the maladies of that most inaccessible part of the body—the cranium—give out no certain sound, and will not disclose themselves to any wizard touch, so it remained for the genius of von Graefe and Sichel, the patient and skilful labors of Saemisch, Liebreich, Schweigger, Soelberg Wells, Jackson, Allbut, Gowers, and others, to illuminate with the ophthalmoscope the dawning light, through which men were eagerly striving to discover the connection between amblyopia and intra cranial disease The popular idea that the oculist has, and perchance needs, no knowledge of general medicine to successfully treat the eye, is no less false than the, I fear, professional belief that the general practitioner can gain little from the ophthalmoscope With the herculean task of gaining a fair knowledge of the structure, working, derangement, and repair of the general system, it is not to be expected that even a Hercules could also keep abreast of the information and experience in regard to any special organ Yet, since the whole is made up of all its parts and the parts are inter dependent, and dependent upon the whole, any approach to a comprehension of the whole organic system must involve some familiarity with every part No more striking illustration of this can be cited than the evidence of cerebral lesions that may be elicited by an ophthalmoscopic examination of the intra-ocular end of the optic nerve, called the optic disc or papilla In the pre ophthalmoscopic period (prior to the great invention of Helmholtz in 1851), there certainly had been *something* done to trace in atrophy of the optic nerve, the connection between amaurosis and brain disease, but the ophthalmoscope first revealed an *inflammation* of the optic nerve accompanying brain disease It frequently happens that patients having symptoms of encephalic disease accompanied by perhaps very considerable optic neuritis, which *may not* impair vision, have no disposition to consult an oculist, and while so few men in general practice use the ophthalmoscope, one of the most unequivocal signs of encephalic disease, viz optic neuritis, is frequently overlooked The appearance of the optic disc, the first time I succeeded, with the aid of a mirror and lens, in getting a view of it, struck me as resembling a diminutive cream rose full moon, about the size of a large split pea, rising in a pink sky of surrounding choroid, which, by its contrasting color, gave a well defined sharp border to the disc

The changes in the optic papilla, produced by cerebral disease, are congestion, inflammation, and atrophy The congestion of the papilla may be a simple hyperæmia, if attended by œdema, it is the stauungs papilla of von Graefe, the choked disc of Allbut, or, congestion papilla In optic neuritis, the papilla alone may be affected, in other cases the neuritis occupies the length of the optic nerves, as has been shown in autopsies by Allbut, Gowers, Hulke, Virchow, etc

Atrophy of the disc may be primary or simple, or consecutive to papillitis Authorities are in accord as to the great frequency of optic neuritis in intra-cranial disease Aunuske and Reich collected eighty eight cases of intra-cranial growths with ophthalmoscopic examinations and autopsies, and found ophthalmic changes in seventy-five per cent Tumor of brain is nearly always attended by optic neuritis (Hughling-Jackson) Allbut writes "My own opinion certainly is that changes of a congestive, neuritic, or atrophic character may be found in the discs at some time or other in the course of almost all cases of intra cranial tumor" "From my own experience (Gowers) I should say that optic neuritis occurs in about four-fifths of the cases of intra cranial growths" Also, by common consent, the most fre-great cause of optic neuritis is intra cranial tumor, [illegible] meningitis Cerebral abscess and softening are occasional causes, and hæmorrhage a very rare one Encephalic disease may also manifest itself through paresis or paralysis of the ocular muscles—a paretic squint and double vision

---

[1] Read before the Chicago Pathological Society Oct 12 1885

That optic neuritis may possess diagnostic significance of brain lesion, the extra cranial causes which produce or are associated with neuritis must be borne in mind such as albuminuria, tobacco, alcohol, and lead poisoning, the exanthemata, suppression of the menses pernicious anæmia, loss of blood, exhausting diseases neuralgia of the fifth nerve, tumors in the orbit and in rare cases secondary syphilis (Nettleship) and "it may occur idiopathically without obvious cause Hyperæmia is sometimes the expression of a state of congestion and degeneration of the whole optic nerve, but sometimes limited to the disc" (Gowers) It is frequently the first stage of tobacco amblyopia, the last being atrophy

Choked disc, or hyperæmia with œdema, is the first stage of neuritis, and frequently associated with it Its principal causes are said to be the same as produce neuritis, viz tumors, meningitis and hydrocephalus

Primary atrophy of the disc is more frequently associated with locomotor ataxia than with any other disease Often I have seen it occur without assignable cause, and once from a blow on the eye Galezowski gives a table of 166 cases, embracing the causes of primary and consecutive atrophy

Cerebral causes	40
Locomotor ataxia	33
Traumatic	22
Alcoholism	13
Syphilis	12
Other causes	46
	166

Allbut is of the opinion that primary atrophy is generally due to mischief at the base of the brain—tumor—or to ventricular dropsy, which may compress or sever the nerves or tracts at some point in their course From the evidence of numerous observers and my own experience, I believe tobacco in excess will produce atrophy of the discs, though some deny it To be able to distinguish between a normal and the inception of a pathological appearance of
the papilla, much experience is required, and the
tempt will soon prove the saying "Pathology is
the shady side of physiology" A full-blown neu
may be quite palpable to an amateur ophthal
scopist, while an expert may with difficulty de

surrounding choroid, that frequently it can only be distinguished as the point of convergence of the retinal vessels, which may be here and there concealed by exudation, and there may be hæmorrhage Impairment or loss of sight is the chief symptom in optic neuritis, though there may be marked neuritis without any impairment of vision Pain in the eye is rare, vision usually begins to fail first in one eye, and may fail completely in a few days or decrease very slowly Restriction of the visual field is common, and color vision is frequently defective The neuritis of tumor is double, rarely unilateral, and, it appears, is usually a late production, but in many cases in which the cerebral symptoms are latent in the early stage the ophthalmoscope can give valuable help

Jackson records a case in which a man had had symptoms of cerebral tumor for nine years, during the last three years his discs had been repeatedly examined and found normal, six weeks before death neuritis was discovered He has pointed out that neuritis often coincides in its onset with an obvious increase in the other symptoms of the cerebral tumor

The signs of *atrophy* are pallor, and, later, depression of the disc, with shrinking and absence of the capillaries When the atrophy is marked, there is diminished vision, nearly always more considerable in one eye than the other There is a concentric irregular marginal limitation of the field of vision Frequently color-vision is defective

The *relation* of optic neuritis to intra-cranial disease is still a somewhat vexed question I shall refer briefly to the principal theories Von Graafe gave the first in 1859 He distinguished two cases In one the change in the disc (neuritis) was slight, with a tendency to invade the adjacent retina In this case there was meningitis at the base of the brain, and inflammation of the optic nerve trunk was found by Virchow, which inflammation was assumed to have been communicated to the optic nerve from the inflamed meninges This Von Graefe designated descending neuritis In other cases of considerable swelling, hæmorrhages and vascular distension of the papilla (the stauungs [engorged] papilla or "ascending neuritis" of Von Graefe, the "choked disc" of Allbut, the "papillitis" of Leber), accompanied by cerebral tumor, no signs of inflammation were
ceptible on naked eye examination of the trunk
he o tic nerve This engorged papilla he at-
the tumor which encroached upon the
space, and indirectly pressed upon the
nus, thus obstructing the return of blood

The theories of Schmidt and Manz are largely accepted in Germany Manz showed that fluid distension of the vaginal space around the optic nerve is frequent in neuritis, and believed the distension to be due to subarachnoid fluid which is forced into the vaginal space by intra-cranial tumors, and so forth Further, he found that injections into the subarachnoid space of animals passed into the optic sheath, and caused fulness of the retinal veins, and in some cases transient redness and swelling of the papilla Schmidt demonstrated that a colored liquid injected into the sheath, passed into the lymph space of the nerve at the lamina cribrosa, and suggested that neuritis is produced by the irritation of the liquid passing into the lymph spaces

A theory was put forward by Schmidt in 1860, extended by Hughlings Jackson in 1863, supported by Brown-Sequard, and was formulated by Benedict in 1868 It assumes that the tumor acts as a source of irritation, which has a reflex influence through the vaso motor nerve upon the optic-disc, leading to its inflammation

Of these theories, that which accounts for changes in the disc, by inflammation of the meninges propagated along the optic sheath, and finally to the papilla, appears the best supported, by the frequent determination upon post-mortem examinations of the conditions upon which the theory is based Although neuritis may occur in tumor of any size or kind, in any part of the brain, it is rare in tumor of the convexity, while it is common in basilar growths, and most common when the anterior lobes are involved (Russell Reynolds) Again, meningitis limited to the convexity is *seldom* accompanied by intra-ocular changes, while *basilar* meningitis is *usually* attended by neuritis In many cases of tumor a local meningitis in the vicinity of the growth, accompanied by inflammation of the optic tract, has been noticed Now the proximity of this inflammation of the basilar meninges (whether independent, or the result of tumor) to the optic tracts, makes its communication to the tracts highly probable, and the fact of the so common association of inflammation of the meninges and tract increases the probability to a seeming certainty

Time will not allow more than mention of optic neuritis due to hydatid cysts of the brain, to chronic tubercular basilar meningitis, and traumatic meningitis, to general thickening of the cranial bones, and the consequent narrowing of the optic foramina We may also refer to simple atrophy of optic nerve caused by pressure of distended third ventricle on the chiasma, and by concussion of the optic nerve and retina, also to cases of optic neuritis accompanied by intra cranial bruits, several of which have been reported by Dr Holmes In one of these cases an autopsy disclosed an aneurism of the internal carotid

In conclusion, I have selected notes of some hastily reported cases in illustration

Case 1 —Mary L, aged 20, was admitted under my care into the St John (Canada) General Public Hospital July 19th, 1878, with both eyes *stone blind* The blindness of the right eye came on suddenly three weeks previously, and was preceded during the day by severe pain in the brow, which has kept her awake most of the time since Two days before admission she lost the sight of the left eye in a similar manner to the right Patient is very nervous, with slight choreic movements of the arms A year ago had, during three weeks, constant pain in the top of the head, and vomited three to four times daily

She denies syphilis, but two ulcers on the calf of the leg have all the characters of specific sores The eyes at rest both look to the left When the right eye fixes for a near point, the left diverges There is no perception of light, to which the pupils react very imperfectly

Diagnosis White atrophy of both optic discs Probably cerebral syphilis at the base, involving optic nerves Treatment Potass iod, grs x, tr cinchonæ, ʒi, t i d

Aug 8th —The right eye sees the position of the window, no light perception with the left ℞ Hyd perchlor, gr $\frac{1}{12}$, ammonia mur, grs v, tr nucis vom, m x, t i d Discontinue potass iod

Aug 20th —℞ Ung hydrarg, ʒss to be rubbed on alternate days into axillæ and thighs ℞ Pil hydrarg, grs ij, t i d

Oct 12th —No ptyalism ℞ Potass iod, grs v, sp am aromat, ʒi, tr cinchonæ, ʒi, t i d Stop other medication

Oct 22d —Mouth very sore and marked mercurial fœtor Discontinue P I ℞, Potass chlor

November 7th —Right eye no light perception. Left eye counts fingers at thirteen inches ℞ Potass iod, grs x, t i d

April 9th, 1879 —For the past three and a half months strych sulph has been given hypodermically from gr $\frac{1}{24}$ to gr $\frac{1}{8}$, then reduced to gr $\frac{1}{16}$ b d Has had tenotomy of the right internal and left external recti muscles The choreic movements and headache have disappeared Direction of eyes much improved, but they still look slightly to the left The right eye now distinguishes light, and the left reads No 200 at twelve feet Discharged

Case 2 —J K H, æt 53, admitted into the St John Hospital July 5, 1881 He is a muscular looking man, four feet ten inches high, and weighs about 130 pounds During the past year he has had a very dizzy head, and would fall any day, but would soon be able to rise again and walk on The fall was always preceded by giddiness Six months ago he began to vomit about every second day, and soon after vomited every morning, if he laid in bed until 7 o'clock When he rose earlier the vomiting did not come on This continued up to last week, since then the vomiting has completely ceased During the past month has had a pretty severe pain from the forehead to the back of the head, lasting an hour or two daily, and he could not see to read Memory failing for past year Pulse 68, small and rather weak, skin, normal temperature to touch, appetite good, bowels costive, sleeps well, whistles feebly, grasp of hands weak, flexion of fore-arms and legs strong, gait so unsteady he seems in constant danger of falling, patellar reflex normal, no lightning pains, pupils dilated by atropine, right ear hears the quent cause of optic neuritis is intra-cranial tumor, next to it meningitis Cerebral abscess and softening are occasional causes, and hæmorrhage a very rare one Encephalic disease may also manifest itself through paresis or paralysis of the ocular muscles—in paretic squint and double vision

That optic neuritis may possess diagnostic significance of brain lesion, the extra cranial causes which produce or are associated with neuritis must be borne in mind, such as albuminuria, tobacco, alcohol, and lead poisoning, the exanthemata, suppression of the menses, pernicious anæmia, loss of blood, exhausting diseases, neuralgia of the fifth nerve, tumors in the orbit, and in rare cases secondary syphilis (Nettleship), and "it may occur idiopathically without obvious cause Hyperæmia is sometimes the expression of a state of congestion and degeneration of the whole optic nerve, but sometimes limited to the disc" (Gowers) It is frequently the first stage of tobacco amblyopia, the last being atrophy

Choked disc, or hyperæmia with œdema, is the first stage of neuritis, and frequently associated with it Its principal causes are said to be the same as produce neuritis, viz tumors, meningitis and hydrocephalus

Primary atrophy of the disc is more frequently associated with locomotor ataxia than with any other disease Often I have seen it occur without assignable cause, and once from a blow on the eye Galezowski gives a table of 166 cases, embracing the causes of primary and consecutive atrophy

Cerebral causes	40
Locomotor ataxia	33

	166

Allbut is of the opinion that primary atrophy is generally due to mischief at the base of the brain—tumor—or to ventricular dropsy, which may compress or sever the nerves or tracts at some point in their course From the evidence of numerous observers and my own experience, I believe tobacco in excess will produce atrophy of the discs, though some deny it To be able to distinguish between a normal and the inception of a pathological appearance of the papilla, much experience is required, and the attempt will soon prove the saying "Pathology is but the shady side of physiology" A full-blown neuritis may be quite palpable to an amateur ophthalmoscopist, while an expert may with difficulty decide as to a slight hyperæmia of the disc, or say whether pallor is due to incipient atrophy or simple decoloration *The* indication of hyperæmia is an abnormal redness, which has a tendency to blur the edge of the disc Comparing the discs may give some help, and noting whether the redness increases from time to time,

The signs of *choked disc* and *neuritis* are similar, and vary with the stage In the first stage, the disc is slightly swollen and red, the edge, though blurred, may be still distinguished, while in intense papillitis, the color of the disc is so blended with that of the surrounding choroid, that frequently it can only be distinguished as the point of convergence of the retinal vessels, which may be here and there concealed by exudation, and there may be hæmorrhage Impairment or loss of sight is the chief symptom in optic neuritis, though there may be marked neuritis without any impairment of vision Pain in the eye is rare, vision usually begins to fail first in one eye, and may fail completely in a few days or decrease very slowly Restriction of the visual field is common, and color vision is frequently defective The neuritis of tumor is double, rarely unilateral, and, it appears, is usually a late production, but in many cases in which the cerebral symptoms are latent in the early stage the ophthalmoscope can give valuable help

The *relation* of optic neuritis to intra cranial disease is still a somewhat vexed question I shall refer briefly to the principal theories Von Graafe gave the first in 1859 He distinguished two cases In one the change in the disc (neuritis) was slight, with a tendency to invade the adjacent retina In this case there was meningitis at the base of the brain, and inflammation of the optic nerve trunk was found by Virchow, which inflammation was assumed to have been communicated to the optic nerve from the inflamed meninges This Von Graefe designated descending neuritis In other cases of considerable swelling, hæmorrhages and vascular distension of the papilla (the stauungs [engorged] papilla or "ascending neuritis" of Von Graefe, the "choked disc" of Allbut, the "papillitis" of Leber), accompanied by cerebral tumor, no signs of inflammation were perceptible on naked eye examination of the trunk of the optic nerve This engorged papilla he attributed to the tumor which encroached upon the intra-cranial space, and indirectly pressed upon the cavernous sinus, thus obstructing the return of blood from the eye through the ophthalmic vein This latter theory was much weakened when Sesaman pointed out the extensive anastomosis of the superior ophthalmic with the anterior facial veins, through which the vena centralis retina could empty itself in spite of obliteration of the sinus A case of Mr Hutchinson's, in which no distension of the retinal veins was produced, although the sinus was completely obliterated by the pressure of an aneurism, seems quite conclusive against the theory of obstructed blood return from the eye by pressure on the sinus

The theories of Schmidt and Manz are largely accepted in Germany Manz showed that fluid distension of the vaginal space around the optic nerve is frequent in neuritis, and believed the distension to be due to subarachnoid fluid which is forced into the vaginal space by intra cranial tumors, and so forth Further, he found that injections into the subarachnoid space of animals passed into the optic sheath, and caused fulness of the retinal veins, and in some cases transient redness and swelling of the papilla Schmidt demonstrated that a colored liquid injected into the sheath, passed into the lymph space of the nerve at the lamina cribrosa, and suggested that neuritis is produced by the irritation of the liquid passing into the lymph spaces

A theory was put forward by Schmidt in 1860, extended by Hughlings Jackson in 1863, supported by Brown Sequard, and was formulated by Benedict in 1868 It assumes that the tumor acts as a source of irritation, which has a reflex influence through the vaso motor nerve upon the optic-disc, leading to its inflammation

Of these theories, that which accounts for changes in the disc, by inflammation of the meninges propagated along the optic sheath, and finally to the papilla, appears the best supported, by the frequent determination upon post-mortem examinations of the conditions upon which the theory is based Although neuritis may occur in tumor of any size or kind, in any part of the brain, it is rare in tumor of the convexity, while it is common in basilar growths, and most common when the anterior lobes are involved (Russell Reynolds) Again, meningitis limited to the convexity is *seldom* accompanied by intra-ocular changes, while *basilar* meningitis is *usually* attended by neuritis In many cases of tumor a local meningitis in the vicinity of the growth, accompanied by inflammation of the optic tract, has been noticed Now the proximity of this inflammation of the basilar meninges (whether independent, or the result of tumor) to the optic tracts, makes its communication to the tracts highly probable, and the fact of the so common association of inflammation of the meninges and tract increases the probability to a seeming certainty

Time will not allow more than mention of optic neuritis due to hydatid cysts of the brain, to chronic tubercular basilar meningitis, and traumatic meningitis, to general thickening of the cranial bones, and the consequent narrowing of the optic foramina We may also refer to simple atrophy of optic nerve caused by pressure of distended third ventricle on the chiasma, and by concussion of the optic nerve and retina, also to cases of optic neuritis accompanied by intra cranial bruits, several of which have been reported by Dr Holmes In one of these cases an autopsy disclosed an aneurism of the internal carotid

Diagnosis White atrophy of both optic discs Probably cerebral syphilis at the base, involving optic nerves Treatment Potass iod , grs x, tr cinchonæ, ʒi, t i d

Aug 8th —The right eye sees the position of the window , no light perception with the left ℞ Hyd perchlor, gr $\frac{1}{12}$, ammonia mur , grs v, tr nucis vom, m x, t i d Discontinue potass iod

Aug 20th —℞ Ung hydrarg, ʒss to be rubbed on alternate days into axillæ and thighs ℞ Pil hydrarg, grs ij, t i d

Oct 12th —No ptyalism ℞ Potass iod , grs v, sp am aromat , ʒi, tr cinchonæ, ʒi, t i d Stop other medication

Oct 22d —Mouth very sore and marked mercurial fœtor Discontinue P I ℞, Potass chlor

November 7th —Right eye no light perception. Left eye counts fingers at thirteen inches ℞ Potass iod , grs x, t i d

April 9th, 1879 —For the past three and a half months strych sulph has been given hypodermically from gr $\frac{1}{24}$ to gr $\frac{1}{8}$, then reduced to gr $\frac{1}{16}$ b d Has had tenotomy of the right internal and left external recti muscles The choreic movements and headache have disappeared Direction of eyes much improved, but they still look slightly to the left The right eye now distinguishes light, and the left reads No 200 at twelve feet Discharged

Case 2 —J K H , æt 53, admitted into the St John Hospital July 5, 1881 He is a muscular looking man, four feet ten inches high, and weighs about 130 pounds During the past year he has had a very dizzy head, and would fall any day, but would soon be able to rise again and walk on The fall was always preceded by giddiness Six months ago he began to vomit about every second day, and soon after vomited every morning, if he laid in bed until 7 o'clock When he rose earlier the vomiting did not come on This continued up to last week, since then the vomiting has completely ceased During the past month has had a pretty severe pain from the forehead to the back of the head, lasting an hour or two daily, and he could not see to read Memory failing for past year Pulse 68, small and rather weak, skin, normal temperature to touch, appetite good, bowels costive, sleeps well, whistles feebly, grasp of hands weak, flexion of fore-arms and legs strong, gait so unsteady he seems in constant danger of falling, patellar reflex normal, no lightning pains, pupils dilated by atropine, right ear hears the watch only within half an inch, ordinarily loud voice at ten feet, left ear hears the watch only in contact, or ordinary voice at four feet, speech broken, Dutch-English, probably normal, vision, right eye counts fingers at two feet, left eye counts fingers at twelve feet, urine normal Ophthalmoscopic examination shows intense double optic neuritis, with hæmorrhages, and infiltration of retina and discs There is probably tumor of the cerebellum involving the tubercula quadrigemina

June 25th —The left pupil a little small, reacts imperfectly to light Right pupil half the size of left, reacts very imperfectly, percussion on the temples hurts a little, on the forehead less, head twenty-four inches in circumference

July 15th —Last evening and this morning refused to take his medicine, saying there was something in it to poison him

July 24th —Discharged at his own request

Case 3 —Sarah B , æt 36, single, admitted into St John Hospital February 9, 1881 First noticed two months ago that the left eye could not see daylight Three days ago the right eye failed so much as to be unable to read ordinary type Three years since was confined to bed for six weeks with constant, severe pain in the top of the head Was at times very chilly and again very hot and thirsty The head was very hot No vomiting This pain was finally much relieved by the application of iced water to the head, but has been very severe most of the time since, up to the present Memory is failing, and she feels stupid Pulse eighty, weak, sleeps very badly, appetite poor, no history of syphilis, mother and one brother died of phthisis With right eye can count fingers within six inches The left has no perception of light The fundus of the right eye normal in appearance Advanced optic atrophy of the left The atrophy probably neuritic, and the result of meningitis

March 26th —Has been treated with potass iod , potass brom , and hydrarg perchlor and cold water to the shaved head Right disc normal in appearance Discharged relieved of pain, but vision about the same as upon entering Returned to the hospital on August 17, 1881, with headache and nausea The sight of the right eye began, three weeks ago, to get worse, and she cannot now distinguish light with either eye Pupils large and immovable There is now atrophy of the right optic disc as well as of the left Pulse 104, small and weak ℞ Hydrarg sub mur , gr $\frac{1}{6}$ every hour

Aug 20th—Severe pain in the head continues ℞ Potass iod , grs x, t i d

Aug 22d —No pain in the head A prominence noticed over the left frontal eminence (osteoma)

Oct 27th —Discharged with perception of light with right eye only, the head ache absent for several weeks, and the frontal prominence much reduced

Remarks —The prompt relief of the head-ache and the frontal prominence by potass iod points to a specific origin of the atrophy of optic discs in spite of the absence of a syphilitic history

Case 4 —Concussion of the brain, and probably of the retinæ, followed by atrophy of the discs Rev D B consulted me Oct 5th, 1883 Last April was thrown backwards from a buggy, striking the ground with the back of his head After recovering in a few minutes from insensibility, felt nausea The injury did not confine him to the house Since then has had a feeling of pressure on the front of the head, and sometimes behind the eyes Every few nights is sleepless and has tinnitus aurium, "rain like sounds" The sight began to fail a few days after the accident, and in a fortnight he was unable to read Has photopsies Vision, right or left eye, $\frac{1}{10}$ Blueish white atrophy of both discs ℞ Strych sulph , gr $\frac{1}{48}$ t i d ℞ Potass brom , grs xv and repeat p r n in evening The patient was not again heard from

A CASE OF SPINAL ATAXIA WITHOUT LOSS OF SENSATION AND WITH INCREASED PATELLAR-TENDON REFLEX A CONTRIBUTION TO THE STUDY OF SPINAL ATAXY[1]

BY MORTON PRINCE, M D

PHYSICIAN FOR NERVOUS DISEASES OUT PATIENT DEPARTMENT BOSTON CITY HOSPITAL AND AT THE BOSTON DISPENSARY

The case of ataxia which I am about to describe is one of exceptional interest and especially so when studied in connection with Dr Smith's very interesting series of cases of hereditary ataxia, with which it has many points of similarity It resembles hereditary ataxia in the age of the patient (15 years) at which the symptoms developed, the absence of anæsthesia and in fact of all sensory disturbances, the presence of anterior curvature of the spine and nystagmus, and the rapidity with which the symptoms developed It differs on the other hand from this form of ataxia in the facts, of the freedom, thus far, of the rest of the family from the disease, and in the presence and indeed exaggeration of the patellar tendon reflex It differs again from ordinary tabes in this last particular, in the presence of nystagmus, in the absence of all sensory disturbances of every kind, of all cerebral, ocular (pareses) and bladder symptoms It may be a question as to where it should be placed, and indeed the presence of the tendon reflex might be thought to exclude it entirely as tabes, but still I am strongly inclined to believe, for reasons which I shall presently state, that it belongs to the systemic spinal ataxias Another and not the least interesting point connected with the case is the bearing which it has on the disputed question of the pathology of ataxia There is still a difference of opinion existing among neurologists as to the cause of ataxia Some holding that it depends purely upon the loss of sensation, (including sense of touch, muscular sense, etc), others that it is a purely motor disturbance due to an impairment of the motor coordinating impulses The sensory theory would be disproved if, as Erb has pointed out on the one hand, cases of complete anæsthesia should be discovered in which no ataxia existed, and on the other if well-marked ataxia should be found with no loss of sensation A few cases of this latter class have already been reported, and one in particular by Erb,[*] which will be mentioned more in detail later In this case there was also complete absence of anæsthesia in every form, while the tendon reflexes were present These cases show that though loss of sensory impulses may possibly by themselves induce the loss of the power of coordinating movements, ataxia must also have a motor origin and probably be due to a disturbance of the motor coordinating tracts The complete overthrow of the sensory theory would be accomplished by the occurrence of a case of total anæsthesia without ataxia

---

[1] Exhibited before the Section for Clinical Medical Pathology and Hygiene of the Suffolk District Medical Society June 9 1885

Mary D , 17 years of age on September 23, 1885 Her present illness is dated by her mother from January 3, 1884, when the girl came home from school complaining of weakness of the legs and malaise She has never been to school since The mother admits, however, that during the preceding two months, the daughter had not felt well, and complained of weakness I first saw the patient in the early summer of 1884, and have examined her occasionally from time to time since As her symptoms have remained, with the exception of one or two particulars, essentially the same during all this time her present condition will be here given, stating at the same time such changes as have occurred in the progress of the disease

Gait, muscular power, etc The patient can hardly walk or stand without the aid of support She habitually uses crutches, and only can be made to walk unassisted after persuasion, when left to herself she easily topples over though she can manage to get across the room It is evident that she has not the typical ataxic gait, but rather scuffs along with her feet, taking short, slow, careful steps She gives at first the impression of having advanced paresis of the legs But further examination showed this view to be erroneous, for when supported laterally so that she cannot fall, she can lower or raise herself on either leg When told to flex and extend her legs against resistance, it is manifest that their muscular strength is good, though I think they are not as strong as normal When, again, lateral support is given to her by placing the hands firmly against both her sides, and her courage is restored, she can raise her feet and walk fairly naturally When walking, or when standing with her heels and her toes together but eyes open, she topples over after a few seconds and must be well balanced to stand at all With her eyes closed she tumbles somewhat more readily She stands and walks with her feet wide apart She does not reel, or pitch in one direction more than another, but rather tumbles like any inanimate thing which has lost its equilibrium In other words there exists *static ataxia*,

There also exists incoordination of the motion of the legs, but in a minor degree When told to describe a circle on the floor with the toe, a most irregular figure results She cannot accurately touch with the toe any small object, but reaches it by moderately zig zag movements It is a question whether more of an ataxic gait would not be shown if she could maintain the equilibrium, and could walk with less caution and more quickly The left leg is more ataxic than the right The hands are also ataxic, the left decidedly, the right slightly This is shown by difficulty in picking up small objects, buttoning her clothes, touching the top of her nose with her eyes shut

Sensation There is absolutely no loss of the senses of touch, pain, or temperature When I first saw her, about fourteen months ago, I thought there was slight diminution of the muscular sense, not very marked, but still sufficient to be detected I am unable, however, to discover any at all She recognizes the slightest passive move of her legs, can accurately locate their position, and can feel the slightest faradic contraction of the muscles Sensation as tested by faradism is also normal There have been no lightning pains or girdle sensations When first seen in 1884, she said she had a slight feeling of numbness in legs, but this has disappeared At that time there was no objective anæsthesia

Reflexes —The patellar-tendon reflexes are not only present, but exaggerated No ankle clonus, the plantar reflexes can only with difficulty be obtained The lumbar reflexes are lively

Muscles —There is no atrophy or rigidity There is no disturbance of the functions of bladder or bowel, no tremor or local paralysis, excepting the possible weakness of legs above mentioned

Nystagmus exists when the eyes are turned to right and left, but none noticeable when the eyes are at rest Last June I did not notice the nystagmus, and do not think it was present at that time I saw it for the first time at the next examination in September

There exists marked anterior *curvature of the spine* in upper dorsal region There have been no psychical symptoms of any kind No vomiting, headach, vertigo (excepting slight dizziness when she attempts difficult feats, and loses her balance

The *eyes* were kindly examined for me by Dr Charles F Williams in June last, and within a few days by Dr O F Wadsworth Both report nothing abnormal in the fundus of either eye As Dr Williams did not observe the nystagmus, there is additional ground for not believing it to be present in June

There is no syphilitic history, and no neurosis in the parents or collateral branches can be discovered Up to date, there have been eight children in the family The youngest is at time of writing only five days old, and one died in infancy Of the other six children, I have personally examined four and found all but the subject of this paper healthy The mother describes the remaining two free from all disease

As Mary D , first complained of weakness in November or December of 1883, she was little more than 15 years old when the first symptoms developed

That the diagnosis in this case is not placed beyond doubt, must be frankly admitted But, it seems to me that it is highly improbable that the case is one of cerebellar disease, in view of the character of the drug, and of the absence of all headache, vertigo, vomiting, convulsive attacks, and the normal condition of the eyes

Of the spinal diseases, the only ones to be thought of are multiple sclerosis and Friedreich's disease

---

[*] Neurologisches Centralbl No 2 1885

On first seeing the case, I was inclined to regard it as one of the multiple sclerosis because of the lively patellar reflex; but now, after watching the case for nearly a year and a half, I believe the lesion will prove to be that of Friedreich's disease. This view is based on the absence of the peculiar tremor of multiple sclerosis, the absence of ankle clonus, local paralysis (especially of the ocular muscles), and of spastic rigidity of the muscles; the absence of all cerebral symptoms, as vertigo, headache, psychical disturbances, etc. Furthermore, it is as difficult to explain the increased patellar reflex by a multiple sclerosis as by a posterior sclerosis; for any lesion of the lumbar enlargement which would cause the ataxia, would abolish the reflex, and if the lumbar enlargement is not involved, the increased reflex is compatible with a posterior sclerosis. This will be referred to again in speaking of the pathology of the disease.

It may be well to recall here the features which distinguish Friedreich's disease from ordinary tabes.[1] In the first place, there is the tendency to attack many members of the same generation, in the same family, while ordinary tabes does not run in families. Then Friedreich's disease attacks early in life, while ordinary tabes is a disease of middle age or of later life. Out of thirty six cases, in fifteen the first symptoms came on at 10 years of age or under, and thirty-two were 20 or under.

In ordinary tabes, pain and anæsthesia are prominent and almost constant symptoms; in Friedreich's form, disturbances of sensibility are usually insignificant, come on late in the disease, and often are entirely absent. Other peculiarities of the latter form, are the rapid extension of the ataxy from the feet to the hands, impaired articulation, nystagmus, and curvature of the spine. On the other hand, many symptoms which are common in typical tabes are absent in the hereditary variety,—such as lightning pains, anæsthesia, disturbances of the bladder, transient paralysis loss of pupillary reflex, optic atrophy, visceral lines, etc. (Omerod). In both, the patellar-reflex is absent. It will be noticed that the symptoms in Mary D's case present a typical picture of the hereditary form, excepting that none of her brothers or sisters have thus far been attacked (all are younger than the patient), and the patellar reflex is present and rather exaggerated.

There is the youth of the patient, the rapid progress of the ataxia spreading to the arms within six months, the nystagmus, the spinal curvature, and the absence of the other symptoms commonly met with in ordinary tabes. Difficult articulation we should hardly expect to meet at this early stage of the disease. The fact that no other case has thus far occured in the same family, will hardly militate against this case being regarded as Friedreich's form of tabes, considering the ages of the other children, and also the fact that a case has already been recorded which stood alone in the family. The absence of sensory disturbances is peculiar to this form of tabes.

As to the retention of the patellar-tendon reflex, it is a significant fact that it is not a very rare thing in ordinary tabes for the patellar reflex to be preserved, and two cases have been observed, one by Ross and one by Erb, in which the patellar tendon reflex was increased. But more than this, the clinical evidence in favor of regarding the case of Mary D., as one of Friedreich's ataxia, (posterior sclerosis), is still further strengthened by three observed cases of ataxia in one, of which *normal sensation* was combined with *normal patellar-reflex*, and in the other two with *exaggerated patellar-reflex*. These cases are so valuable that it will not be out of place to briefly mention them here. The first case is reported by Erb.[2] It was that of a man 52 years of age, who, when he came under Erb's care, exhibited marked and typical ataxia. When he walked side by side with a patient, with typical tabes no difference in the gait could be distinguished. There had been no lightning pains, there was no paræsthesia or anæsthesia of any kind and no girdle pains; the pupils and ocular muscles were normal, there were no bladder symptoms. There were also no cerebral symptoms of any kind. The patellar-tendon reflexes were present. For the same reasons I have given above in the case of Mary D., Erb regarded this case as one of spinal ataxia, though unwilling to commit himself as to the exact lesion of the cord.

This seems to be the place, before giving the other two cases, to speak of Kast's[3] two cases, in which with slight anæsthesia and no loss of muscular sense at all, there was exquisite ataxia, while the patellar-tendon reflex was present.

The first of these cases was one of myelitis from compression following fracture of the vertebræ caused by a fall. There was complete paraplegia, slight loss of sensation, but gradual motor recovery in eight weeks. When full motor power in the legs had returned, ataxia was developed. Both knee jerks were readily obtained, but there was no ankle clonus. The plantar reflexes were active. In the right leg ataxia and loss of sensibility to touch and pain were more marked than in the left, but there was no loss of muscular sense; the sphincters were not affected.

The second case was one of acute transverse myelitis, with complete motor and almost complete paralysis of both legs to touch, temperature and pain. In this case also, on return of motor power, decided ataxia developed, and persisted even after complete return of motor power. The knee-jerk was well marked and there was ankle clonus on left side but not on the right.

In these two cases, a stage intervened between the complete motor paralysis and return of muscular power, in which, with almost complete motor power, there were considerable defects of coordination and ataxia. I have not been able to obtain Kast's original article, and therefore cannot speak positively of the exact amount of sensory disturbances present, but Erb, referring to them, says: "There was the most exquisite ataxy, without very marked disturbance of sensibility, and especially without any loss of the muscular sense."[4]

---

[1] A very excellent digest with a table of all the cases up to date is given by Omerod in Brain, Vol. vii, page 105.

[4] Neurolog. Centralbl. No. 2. 1885.

The two cases above referred to, wherein normal sensation was combined with increased patellar-reflex, were reported by Seeligmuller[1] as cases of Freidreich's disease They were two brothers whose parents were first cousins, and whose mother and maternal aunt were highly neurotic Both brothers had locomotor and static ataxy, in one the static being predominant In both there was absolutely no loss of sensation, and there existed *increased* patellar-reflex, and nystagmus The plantar reflex was absent in both, the abdominal reflexes were present There was no ankle clonus, and no disturbance of speech

Freidreich, to whom Seeligmuller sent his cases for an opinion, expressed a doubt as to whether they were true cases of his disease, presumably in view of the presence of retained patellar reflex and the presence of psychical symptoms which existed in both, namely forgetfulness and dreamy states in one, and forgetfulness, migraine, dreaminess, and inverted sexual passions in the other But, as Seeligmuller points out, the father, who was otherwise perfectly well, had the same forgetfulness, and, as Omerod remarks, the connection between tabes and paralysis of the insane is well known Even if there should have been some cerebral disease, it would scarcely account for the spinal symptoms It seems to me, all things considered, that Seeligmuller was more likely right

Not the least interesting question connected with the case of Mary D is the seat of the lesions in the cord It is a remarkable fact, considering the grouping of the symptoms, that out of seven autopsies[2] of Freidrich's disease thus far recorded[3] (including the case reported by Kahler and Pick), in six there was found sclerosis, not only of the posterior columns, but of the lateral as well In several there was sclerosis of anterior columns Of these seven cases, the condition of the tendon-reflexes was, unfortunately, noted in only three, in all three the patellar-reflex was absent, though there was lateral sclerosis as well

How are we to explain the absence of all symptoms of lateral sclerosis in these cases on one hand, and, on the other hand, of the presence of the knee-jerk in exceptional cases of ordinary tabes, and of the exaggerated jerk in Seeligmuller's cases and mine? The key to this question I believe is given by the autopsies of other cases of systemic spinal disease, not Freidreich's, in which a combination of systemic lateral and posterior sclerosis existed An excellent digest[4] of these cases has also been made by Omerod, who has collected twenty cases in all Of these, the patellar-reflex was lost in eight and exaggerated in six cases, reported by Strumpell (two cases), Westphal (one case), Raymond (one case), Rabasin (one case), and Dejérene one case Of these, the most instructive was Déjérene's[5] The symptoms were those of tabes, namely slight locomotor but marked static ataxy, *exaggeration of patellar-reflex, ankle clonus*, paresis of legs, anæsthesia and analgesia of the legs, distributed in patches Death from broncho-pneumonia At the autopsy there was found chronic posterior spinal meningitis, atrophy of posterior nerve roots and cutaneous nerves, sclerosis of lateral columns in lumbar and dorsal regions This sclerosis was wedge shaped, the bone reaching the periphery and occupying the posterior part of the lateral columns, but stopped before reaching the posterior bone (wrist cerebellar and crossed pyramidal tract?) The posterior columns were sclerosed the whole length, *excepting in the lumbar enlargement*, which was nearly unaffected

In the other four cases, all of which, however, presented more decided spastic symptoms, the disease of the posterior columns did not reach the lumbar enlargement These cases, therefore, support Westphal's opinion, based on his one case where the spastic symptoms were present, and several other cases where they were not—that if the posterior sclerosis involved the lumbar enlargement, the lateral sclerosis was manifested by paresis only, without rigidity, and the patellar-reflex is absent, but if the posterior sclerosis did not extend into the lumbar enlargement, the symptoms of lateral sclerosis predominate [1]

If the case of Mary D (the subject of this paper), is properly classified as one of Freidreich's disease, we may assume that the disease has not to any great extent involved the lumbar enlargement, and thus explain the fact that the patellar-reflex is not abolished Finally, the exaggeration of the latter may be owing to the same conditions which cause an increased patellar-reflex in transverse myelitis when the lesion is above the lumbar enlargement, or, if we suppose the same anatomical changes to be present which were found in the six autopsies of Freidreich's disease mentioned above, it is possible that the lateral columns are slightly affected This would account for whatever amount of paresis is present

SUN-BLINDNESS[2]

BY C F SINCLAIR, M D,

SURGEON TO THE ILLINOIS CHARITABLE EYE AND EAR INFIRMARY

The danger of blindness from the direct rays of the sun, which appears to have been generally recognized not only by the medical profession but also by the laity of the past generation, is apparently unrecognized to day During the recent eclipse, many might have been seen looking at it with the naked eye It is not uncommon for patients to tell the physician, as a proof of strong vision, that they can look steadily at bright lights, and even at the sun without blinking Children not infrequently undertake competitive trials to see which can gaze longest and most steadily at the sun

In many of the recent smaller works on ophthalmology the subject of sun-blindness is not mentioned Nettleship, Lawson, Williams, Schweiger and De Wecker refer to the possibility of blindness being caused by flashes of lightning, by the bright glare

[2] Read before the Chicago Society of Ophthalmology and Otology August 11, 1885

from snow and from a too prolonged gaze at a brilliant artificial light; but the possibility of a like result following from the direct rays of the sun is not referred to. Soelberg Wells mentions the subject, but in the most cursory manner, simply saying that blindness may follow if the eye is long exposed to bright sunlight. He further points out the difference which may exist in the density of the cloud or disk, and which may last only a few moments, days or weeks, or even longer. The prognosis, in his view, appears to be favorable. No reference is made to any pathological condition. The treatment recommended is rest, protection from bright light by suitable colored glasses, cod liver oil and steel. The majority of recent writers, however, have ignored this as a cause of blindness—a cause which, from the carelessness of adults and the ignorance of children, may well be considered one which is most practical and vital.

In a more recent work by Swanzey, of Dublin, the subject is considered at somewhat greater length. He refers to the semi blind spot which appears in the field of vision after exposure, and which, however, may be absolute. In his experience, even in mild cases, this cloud seldom entirely disappears. The ophthalmoscope shows a small bright white spot at the fovea centralis, surrounded by a blood-red ring which fades off into the normal color.

A recent monograph by Deutchmann, of Gottingen, gives us more definite information as to the pathological conditions in these cases. His investigations were undertaken more particularly with that end in view. He cites four cases which came under his care in 1882. In one of these a blue glass had been used in looking at the eclipse; still, the result was the same. In all the cases, immediately after looking at the sun a small cloud appeared in the centre of the field of vision, and examination showed a small central scotoma. Vision was impaired in the same degree in three of the cases, being $\frac{20}{50}$. In one case which came under observation two months after the first appearance of the blind spot, vision had already considerably improved, seeing $\frac{20}{30}$ without difficulty. The finest print, in all these cases, was read with difficulty. In none of Deutchmann's cases were the scotomata complete, and yet in none was perfect vision recovered. Pathological changes were found in all, viz.: a small bright white spot in the centre of the macula lutea, and around this a blood-red ring which gradually shaded off into the normal retina.

To verify these results, Deutchmann undertook a series of experiments on the eyes of rabbits. The direct rays of the sun were condensed by a concave mirror and then rendered parallel by a convex lens. They were then directed on to the retina through the dilated pupil. The resulting appearances were similar to those seen in the human eye; the small central spot of anæmia with the surrounding ring of hyperæmia—these results following an exposure of only a few seconds' duration. An examination with the microscope showed that an extremely small area of the retina was disorganized by "the coagulation of the albumen in its tissues with hyperæmia, exudation, diapedesis of blood corpuscles and pigment disturbance surrounding it."

Based upon these pathological changes, the unfavorable prognosis which Deutchmann gives in these cases would seem to be well justified. The following case, however, which came under my observation the 28th of last March, presents phenomena difficult of explanation if we accept the view that these pathological changes are an essential element in sun-blindness.

Howard D., a lad 13 years of age, looked at the sun several times during the eclipse of last March. Finally, after a somewhat prolonged gaze, he felt slightly dazzled. Then, wherever he looked, objects seemed colored with quickly alternating shades of green and blue. This lasted half an hour, and then disappeared. His vision continued good until 4 P. M. of the same day, when, looking at the snow or sky, he noticed a dark spot in the centre of the visual field. The spot was quite dark and about eight inches in diameter. It was round with a piece taken off the outer side—this piece representing the position of the moon when the eclipse was last observed. It appeared as if the sun had photographed itself upon the retina. Three days later, a dull ache was felt in and around the eyes.

I first saw the patient twelve days after the accident had occurred. He then told me that the cloud had been constantly growing larger and darker. Vision, on this first examination, was $\frac{7}{10}$ in both eyes. The ophthalmoscope showed no discoverable morbid change in the fundus. The disk, the vessels and the retina all appeared in normal condition.

Subcutaneous injections of strychnia, together with the use of the constant current, were begun. The beneficial effects of this treatment were seen four days later, when the cloud had become less dark and impenetrable, and the outlines of letters representing normal vision, or $\frac{10}{10}$, could be made out within its area. Still four days later, the patient returned to school and attempted to go on with his studies. This resulted in a relapse to $\frac{7}{10}$ vision and an increase in size and density of the scotoma, with a return of the dull aching pain in the eye. April 9, $\frac{10}{10}$ vision was again reached, but the letters could only be deciphered separately after closing and resting the eyes.

April 14.—$\frac{10}{10}$ could be seen clearly for 3".

By April 21, in the R. E., 12" were counted before the cloud came, and even then $\frac{10}{10}$ could be read through it. In the L. E., 6" elapsed before the cloud developed, and through it $\frac{10}{10}$ could be seen only indistinctly.

April 28, a week later, 20" in the R. E., and 10" in the left, indicated a continued improvement.

May 4, the strength of the retina had increased to 28" in the R. E., and at the end of that time, what the patient described as a simple blur came, and $\frac{10}{10}$ could be easily read through it.

May 13.—The R. E. had reached 43" and the L. E. 25", and only the upper half of the test-types was obscure. At this time, owing to considerable swelling and soreness over the temples, the injections of strychnia were suspended, when the strength of the affected portion of retina rapidly deteriorated to 32″ in the R. E. and 15″ in the left. The subcutaneous injections were again commenced, with an improvement in four days of 11″ in the R. E. and 22″ in the left. This improvement was gradual until June 2, when 66″ in the R. E. and 46″ in the left were counted before the development of the scotoma, which at the same time had diminished much in size and density. At this time the patient withdrew from treatment.

The fact that this case, after several exposures, presented no discoverable pathological changes, together with the constant improvement until 66″ was reached, during which time no evidences of the scotoma were manifest, justify the conclusion that in these cases of sun blindness the lesion may be much less serious than that indicated by Deutchmann—being rather of the nature of a paralysis than that of the disorganization of the retinal elements, and, consequently, that the prognosis as to the ultimate recovery of perfect vision is not necessarily unfavorable.

MEDICAL PROGRESS

MATERIA MEDICA AND THERAPEUTICS

Hydrobromate of Hyoscin.—Dr. Archibald Church, of Elgin, Ill., in a short article on this subject, says that in sthenic acute conditions, or violent manifestations arising in the course of chronic insanity, hydrobromate of hyoscin has notably and promptly lessened the excitement, and in the frenzy of melancholia has mitigated the outbreak in cases where it has been tried in this hospital. While not doubting that its continued administration in small and often repeated doses will disarrange alimentation—and what powerful drug does not?—it has yet rendered signal service in tolerably full doses, $\frac{1}{40}$ grain, given when specially indicated, without producing any untoward symptoms whatever. By watching its action upon others, and upon myself, in varying doses, it did not seem advisable to give it in a more routine manner than one does morphia or atropia in parallel cases, and, so far, more than two doses of $\frac{1}{40}$ grain have not been used in twenty four hours.

By careful sphygmographic observations it is clearly shown that minute doses—$\frac{1}{150}$ to $\frac{1}{100}$ grain—of the hydrobromate are stimulant of cardiac action, and thereby of the mental processes and attendant manifestations, not only among the insane, but in a condition of health. With a larger dose—$\frac{1}{40}$ to $\frac{1}{20}$ grain—this also is the primary result, but as more of the medicament comes into operation, it is followed by a slowing of the pulse rate and by a diminution of the cardiac curve of the tracing, sometimes to such an extent that a bruit of dicrotism appears. A feeling of fatigue, or rather of comfortable weariness, if you will permit such a term, is now associated, and one gives up readily to feelings of drowsiness, sleep following naturally. After using the drug in $\frac{1}{40}$ grain doses for from six to ten consecutive nights, with an average of six hours' sleep, for instance, its discontinuance has been followed, but only after several nights, by wakefulness, which again gave way to the remedy. In some instances of confirmed insomnia, or rather of often disturbed sleep, after securing a few nights' good rest the patient has rested fairly well, the habit of waking at certain times being broken, and in general the effect of the drug is lasting. When given by the mouth, as was pointed out in the article above referred to, its action is slow, and there is considerable variability as to the amount required by different patients. Although no notable depression has come under observation from the use of the drug in such doses as are indicated above, it no doubt is capable of producing stupor just as does hyoscyamia, which doubtless in the amorphous form contains it largely, but which is associated with little danger, according to a recent writer in the London *Lancet*, who gave unhesitatingly ½ grain, and even ¾ grain of Merck's preparation, producing coma, etc.

It may be not uninteresting to note that hyoscin is a very active mydriatic. It was found that two drops of a solution $\frac{1}{10}$ grain to the ounce of distilled water produced complete dilatation of the pupil and paralysis of the accommodatory muscles in about five minutes, and that it was more active to stretch the adhesions in a case of posterior synechia than the repeated instillation of a solution of atropia sulphatis three grains to the ounce. The mydriasis so produced is very persistent, lasting from five to ten days, and the use of the solution is not attended, as far as observed, with any conjunctival irritation, which will suggest its value to oculists where the long continued action of a mydriatic is required.

From the little learned concerning the drug, it would seem to be of use in conditions of intensified nerve action, especially of cerebral origin, to meet acute manifestations.—*Med. Record*, Oct. 10, 1885.

MEDICINE

Hydatid Cysts of the Base of the Skull.—M. Odille reports the following interesting case which came under the care of M. Bucquoy. A man, 43 years of age, had been subject for three years to intense cephalalgia, which was constant and extended all over the head. He did not vomit, and had never had convulsions. At times there were lancinating pains down the side of the face. For two years there had been some feebleness of vision and deafness on the left side. Two months before entering the hospital he noticed a tumor on the left side of the neck, and which increased steadily in size. Some weeks later he expectorated something very much like raisin seed, a dozen of these being expectorated in one morning. He then entered the hospital, and the nature of the tumor was established beyond doubt; it was an hydatid tumor, starting from the base of the skull, making a track for itself in the soft tissues of the neck, and pressing on the cranial nerves in the vicinity. There was almost complete prolapsus of the upper eye lid, and paralysis of the external and inferior recti of the left eye. There was dimness of vision on the same side. The muscles of the face were somewhat retracted, the contracture of the left masseter giving rise to some opening of the mouth There was anæsthesia of the left side of the face, and of the buccal and nasal mucous membranes There was no trophic trouble.

The tumor continued to grow, and took on a somewhat phlegmonous appearance It was opened, and a small quantity of pus and a large number of hydatid vesicles escaped Other vesicles were removed at intervals, after which the wound cicatrized The motor troubles persisted, but the sensibility was restored completely on the left side of the face

M Odille refers to the rarity of hydatid cysts of the base of the skull, to the absence of definite symptoms other than those of other tumors of that region, save in the cases in which vesicles are expelled by the nasal fossæ after the appearance of the tumor at the surface He thinks that an exploratory puncture is indicated whenever an hydatid tumor is made out in the temporal or mastoid regions —*These de Paris*, No 377, 1884

EXTRACT OF WILD CHERRY BARK AND CHLOROFORM INHALATION IN STRYCHNINE POISONING —DR GEORGE M KOBER, U S A, reports a case of strychnine poisoning in a Chinaman The symptoms were well pronounced, and after washing out the stomach he administered a tablespoonful of the extract of wild cherry bark, and repeated the dose in twenty minutes, the tetanic paroxysms diminished in frequency and force, and were readily controlled by the inhalation of chloroform The alarming symptoms in the case lasted, however, nearly two hours, yet there was evidence of progressive improvement, and the immediate effect of the wild cherry pointed to an antagonistic action After the expiration of two hours, the only remaining symptoms observed were involuntary twitches and a feeling of stiffness in the muscles, for which potass bromide and chloral were given with good effect, fifteen grains of the former and ten grains of the latter soon induced rest and sleep for a few hours The patient recovered perfectly in two days, complaining only of being tired during this time

His reason for not publishing the case before, was the insufficient evidence of the fact that the extract of wild cherry bark proved absolutely antagonistic to the action of strychnine The stomach had been thoroughly evacuated, the quantity of the poison introduced was unknown, and the effects of chloroform inhalation cannot be overlooked

He has seen in recent years no authority of weight for the use of hydrocyanic acid in strychnine poisoning, but the subject is sufficiently important to experiment on animals and thus determine whether the extract of wild cherry bark possesses advantages over prussic acid —*Medical News*, Sept 26, 1885

THE RELATIONS BETWEEN DISEASES OF THE ABDOMEN AND THOSE OF THE RIGHT HEART —Since the work of Potain in 1878, and the researches of Tessier and Franck in 1879 and 1880, this question has received little attention Passerini now cites three cases of tricuspid insufficiency consecutive to a peritoneal effusion Auscultation showed a prolongation of the first sound and a murmur, the second sound being found strengthened toward the pulmonary orifice The disappearance of the effusion was accompanied by the disappearance of these sounds Passerini believes the cause of these cardiac alterations to be purely mechanical, the compression of the addominal viscera provokes venous anæmia, and engorgement and hyperæmia of the thoracic organs In favor of this explanation we have the observations of Larcher and of Depaul in pregnancy These writers have noted the accentuation of the first sound toward the pulmonary orifice, at the same time that it is prolonged at the level of the base of the xyphoid cartilage The same observation has been made in two cases of ovarian cyst, and in another of large abdominal tumors, and finally, this same modification of the first sound at the pulmonary orifice can be produced by simple compression of the abdominal wall —*Revue Bibliog des Scien Med*, July 31, 1885 —*Medical Record*, October 10, 1885

TWO CASES OF HERPES WITH MOTOR PARALYSIS —DR G WALLER communicates to the *Weekblad* of Amsterdam, notes of two cases of herpes, in which motor nerves were affected A widow-woman, aged 68, had a painful patch of herpes, covering the whole of the right side of the face, stopping abruptly at the middle line After some weeks, the herpetic spots and the pain disappeared, being, however, replaced by paralysis of the same side of the face, with loss of taste on the right half of the tongue The other case was that of an old man, who had a herpetic eruption situated on the anterior aspect of the upper arm on the right side, this was accompanied with severe itching and a pricking sensation Eight days after the appearance of the eruption, he found himself unable to raise or extend the arm There was no pain or swelling in the muscles or joints, and the electrical reactions were normal The herpes and the paralysis both indicated the circumflex and musculo-cutaneous as being the nerves affected The treatment was electrical, and brought the case to a successful termination —*Brit Med Jour*, Sept 19, 1885

RECOVERY FROM LEPRA TUBEROSA —At the recent meeting of the Medical Congress at Wiesbaden, P G UNNA, of Hamburg, reported the case of a woman, 38 years of age, a native of Germany, who had lived fifteen years in Brazil, and had acquired a case of leprosy in an unknown manner It was a pure case of lepra tuberosa, without anæsthesia, extending over the face, arms, legs, and a portion of the trunk She was under treatment in Unna's clinic for four months, and at the end of that time she was cured She was treated with pyrogallol, resorcin, chrysarobin, and sulph-ichthyolate (?) of ammonia A concentrated ointment (10 per cent) of chrysarobin and resorcin acted very well against the nodules, the ichthyol only feebly, while the pyrogallol caused the formation of vesicles During the last three weeks of her stay in the clinic the treatment was mainly directed towards removing the pigmentation and the cutaneous deformity, which was done by a plaster of mercury, carbolic and salicylic acids —*Gazzetta degli Ospitali*, October 7, 1885

THE REDUCTION OF SUPERABUNDANT FAT

In this country the ceaseless activity of both brawn and brain and the nervous temperament of the people, together perhaps with certain climatic influences, are antagonistic to the accumulation of superfluous fat In Germany, on the contrary, and to a minor extent in England, where the conditions of life are less wearing, a tendency to corpulence is not uncommon The people are phlegmatic, and although their struggle for existence is more severe, perhaps, owing to fewer possibilities, it is not characterized by that spirit of haste and rush which in the United States makes life an exhausting race The habitual consumption of large quantities of malt liquors in Germany is also of influence, doubtless, in the production of adipose tissue It is not strange, therefore, that the reduction of superabundant fat should have first received scientific consideration in Great Britain and Germany, and that in the latter country at the present time the safest and most efficient methods for its accomplishment are being earnestly discussed

The principle underlying the various anti-fat treatments is to limit the diet almost exclusively to nitrogenous food, while at the same time sedentary habits are exchanged for a life of exercise in the open air Although agreeing in principle, the various systems now in use differ as to the proportion between the nitrogenous and non-nitrogenous food allowed Before mentioning these differences, however, it may be well to state briefly the rationale of this treatment and the dangers to be avoided With reference thereto we shall transcribe the remarks of Dr J Munck from an article by him in the *Berliner klinische Wochenschrift*, No 13, 1885 Experiments, made to ascertain the metabolic changes which take place in the nitrogenous elements of the animal organism, have taught that the metamorphosis of the albuminous tissues depends, aside from the amount of albumen consumed, upon the condition of the body as respects fat That is to say, the greater the amount of adipose tissue, the less is the quantity of nitrogenous food required to maintain an equilibrium in the metabolism of its albuminous elements, or in other words, to keep repair *pari passu* with waste If, therefore, more albumen be furnished than is required to maintain this balance, it is stored up in the system and the blood is enriched greatly to the benefit of anæmic conditions

On the other hand, if the non nitrogenous food be reduced until the nitrogenous can no longer hold tissue waste in check, the needs of the system are met by the consumption of the stored up fat In consequence, therefore, of the absorption of the adipose tissue, the amount of albumen, which once supplied the requirements of the body, no longer suffices and it should be somewhat increased So also should be the quantity of the hydrocarbons, else the consumption of the body's fat will be too great and react deleteriously upon the general nutrition Hence, the danger in attempting to reduce obesity by restricting the dietary to one that is chiefly nitrogenous, lies in following it out too long as a routine It is only suitable to the first few weeks It may be further stated, that as respects their ability to limit the destructive metamorphosis of the nitrogenous elements of the body, sugars and starches exert an effect equal to that of corresponding amounts of fat, whereas, in checking the consumption of the adipose tissue, one part of the latter in the food is equivalent to two and four-tenths parts of the former

With the foregoing facts as a basis, the proper proportion of the ingredients of the dietary must now be determined, and here, as will be seen, the various methods depart quite widely Chambers appears to have inaugerated the regiminal treatment of obesity in 1850, by excluding all fat from the diet and restricting the amyloid articles He also limited the consumption of liquids In 1863, Dancel announced his method, according to which bread, potatoes, beans, other vegetables and fruit, in all to the amount of 500 grammes were allowed in addition to plenty of meat, also fluids from 500 to 1250 grammes These were soon eclipsed, however, by the Banting system, announced in 1864 This dietary consisted of 500 grammes of lean meat, 80 of toast, 50 to 100 of fresh fruit, a small quantity of vegetables excepting potatoes, tea without milk and sugar, and four to seven glasses of strong wine, equivalent to 170 grammes of dried albumen, ten of fat and eighty of sugar and starch. Upon this diet Mr. Banting lost about thirty-five pounds (sixteen kilos) of his weight in nine months, and reduced his girth about half a yard. The results of this system, which by the way had been suggested by Dr. Harvey, were so brilliant as to make it widely popular. It was soon found, nevertheless, to have serious drawbacks. The allowance of albumen was so out of proportion to the hydrocarbons that individuals who adhered to it closely, speedily complained of general malaise, nervous excitability and sleeplessness, while the consumption of so much meat set up an obstinate catarrh of the stomach and duodenum, as well as other dyspeptic disturbances. To obviate these dangers, Dr. Ebstein adopted a regimen composed of 100 grammes of albumen, 85 of fat and 50 of amyloid food together with 1750 of fluids. His daily bill of fare comprises 300 grammes of meat with rich gravy or rich soup, 80 grammes of buttered toast, a few vegetables with fruit morning and afternoon, and tea without milk and sugar. This dietary certainly accomplishes its purpose, but Munck thinks is not wholly devoid of some of the dangers of the Banting system. Voit, of Munich, again advises a daily regimen containing 118 grammes of albumen, 40 of fat and 150 of sugar and starch, and thus differs very materially from Ebstein.

Finally, Oertel, also of Munich, has recently come forward with still another proportion between the albumen, fat and amyloids. As was mentioned in a previous editorial article, Oertel's plan is varied according to conditions of the circulatory apparatus. In one group corpulence is associated with healthy heart and blood vessels, in the other, the heart has undergone fatty degeneration and the hydrostatic equilibrium is lost. In the first class the object is merely to reduce the fat, while in the second this is to be united with the therapeutic management of the case. In the one, vigorous exercise is enjoined and enough carbon must be supplied to stimulate the bodily energy. In the other, effort is made to build up the atrophic muscles by giving enough albumen to favor its accumulation, that is, its transfer into the nitrogenous elements of the organs.

The hygienic management of these cases has been previously detailed and need not be repeated. For the majority of cases, Oertel recommends a small cup of coffee, with milk and sugar, morning and afternoon, and with the morning coffee 35 to 70 grammes of white bread with butter, at noon no soup, but 200 grammes of beef, 50 grammes of lettuce or the like, and 100 of fresh fruit, for supper, some caviar, two eggs, 150 grammes of meat and 150 to 200 grammes of light white wine. Later, when a portion of the bodily fat has disappeared and the circulatory disturbance is relieved, the daily dietary may be increased by adding 100 grammes each of fish and pudding to the dinner, as well as 200 of wine, and to the evening meal some cheese and bread. Nevertheless, this increased allowance is only admissable when by hearty exercise, preferably mountain climbing, the consumption of carbon is augmented and the system requires more nourishment. In conclusion it may be said that Oertel's daily regimen consists of 155 to 170 grammes of albumen, 24 to 40 of fat, 70 to 110 of sugar and starch, and 900 to 1300 of fluids.

SPORT VERSUS SCIENCE

"The red deer intended for sport with her Majesty's staghounds during the ensuing hunting season were captured yesterday in Windsor Great Park. By noon a score of splendidly antlered stags had been run into the paddock. The gates were closed and stout nets placed across the meadow, round which the deer were driven several times until they had entangled themselves in the meshes and rolled over and over in their efforts to escape from the toils. They were secured by the park laborers, and, having been denuded of their horns, were pushed into wooden boxes and conveyed in farm carts to Swinley Paddocks. Forest hunting will now be commenced by the Queen's buck-hounds, which during this month are expected to meet Tuesdays and Fridays at the Royal Hotel, Ascot. The pack is under the control of the Marquis of Waterford."—*London Standard*, Oct. 6, 1885.—*Chicago Tribune*.

Sir Joseph Fayrer asserts that in India 20,000 human beings die annually from snake bite, but as yet no antidote to the snake-poison has been discovered. But when Dr. Lauder Brunton began a series of experiments to isolate the poison, find out its nature, and search intelligently for its antidote, his work was stopped by the antivivisection laws of England. And with a consistency that is peculiarly charming, the British Government, whose own laws prevent such work in its own country for the benefit of its own subjects, has furnished cobra poison to Drs. Weir Mitchell and Reichert, of Philadelphia, in order that they might make the experiments in America which Dr. Lauder Brunton was forbidden to make in England. So also, when but recently Sir Joseph Lister, the promulgator of the new science of surgery, wished to make some experiments on animals to further perfect surgical methods, he was compelled to leave enlightened England and pursue his studies in "revolutionary France "

In England to day it is a crime to kill or even to use a mouse in the interests of humanity The mouse may be poisoned, or it may be turned over to a terrier to be tortured to death, and nothing is thought of it Hunter's experiment on a deer would be a crime in England to day, unless the experimenter could obtain a license, which would very likely be refused, such an experiment was, and would be, in the interests of humanity But England's Queen has a score of "splendidly antlered stags" run into a paddock, captured, denuded of their horns, and properly prepared for the "sport with her Majesty's staghounds during the ensuing hunting season "

"Forest hunting will now be commenced by the Queen's buck hounds, which during this month are expected to meet Tuesdays and Fridays at the Royal Hotel, Ascot The pack is under the control of the Marquis of Waterford " Now look on this hypothetical picture "Experiments on rabbits will soon be commenced by Dr T Lauder Brunton in order to find a physiological antidote to the cobra poison, and thus put a stop to the holocaust in India The rabbits will be under the personal supervision of Dr Brunton and his assistant " If this were the case, who would be the greater friend to humanity, England's Queen or Dr Brunton? the Marquis of Waterford or Dr Brunton's assistant? Yet, had the *London Standard* contained this announcement in the same column with the twaddle quoted at the beginning of this article, the "*Humane Societies*" of England would have raised such a cry that Her Majesty's Government would have seen to it that Dr Brunton's "cruel experiments" were stopped Australia, under the English Government, has been recently overrun by rabbits, and they are there destroyed in every possible manner They may be poisoned, trapped and killed, as the red deer recently captured in Windsor Park, shot, or hunted with dogs—it matters not how they are tortured or killed, so they are not used for a scientific or humane purpose

These things show an amount of ignorance, inconsistency, and indifference to humanity that would be ludicrous were they not so terrible in their results Professor Yeo estimates, from the reports of vivisectionists, that of 100 experiments on animals seventy-five are absolutely painless, twenty as painful as vaccination, four as painful as the healing of a wound, and only *one* as painful as a surgical operation It does not need the estimate of a professor to show that of twenty deer hunted and caught by dogs, *twenty* will suffer as much as from a surgical operation Does the fact that this useless slaughter of deer is for the amusement of the ruler of a great nation, and the further fact that the instruments of torture are under the control of a Marquis, make it probable that the animals will suffer less? Are the sufferings of animals less acute when the hunter wears a red coat and blows a horn than when the experimenter wears a laboratory apron and administers an anæsthetic? Does the highly intellectual amusement afforded by seeing an animal torn by dogs outweigh the benefits, to science and humanity, gained by experimenting on an anæsthetized animal—or even one which feels every prick of a needle? Perhaps we are to believe that the unnecessary giving of pain for sport is not cruelty, while a practically painless experiment or a necessarily painful operation for solid scientific results is cruelty!

PNEUMONIA, ITS FATALITY—EXAGGERATED STATEMENTS

In the issue of the JOURNAL for October 10, 1885, was an article entitled "Thoughts on Some Points Connected with Pneumonia," in the introductory part of which there were some statements that attracted our attention For instance, on page 393 the writer says "Our predecessors for many long years viewed pneumonia as simply inflammation of lung tissue, and the spoliative treatment adopted by them was in keeping with those views If pneumonia be simply inflammation of lung tissue, and, *vice versa*, inflammation of the lung be pneumonia, certainly it should be treated antiphlogistically, just as it was treated fifty years ago, by blood-letting, purging, and a general depressant course But the *frightful mortality* attending this treatment is a fearful commentary upon it The fatality attending this antiphlogistic treatment was simply appalling And so it continued until J Hughes Bennet called a halt, and adopted a conservative, expectant and supporting treatment, since which time the mortality has been reduced 250 to 500 per cent "

These statements of the writer are doubtless made in perfect sincerity, but they are good specimens of the too common habit of speaking of the practices and opinions of preceding generations in terms of unlimited exaggeration Indeed, it is not rare that a writer or speaker presents the exceptional extravagancies and vagaries of the few in any past period as the rule of action or opinion in the age to which they belong And in relation to no subject is this more true than in regard to what our writer calls the "spoliative" or antiphlogistic treatment of pneumonia If he were to set about the task of furnishing proof of the "frightful" and "appalling" mortality of the former period to which he refers, and of the "250 to 500 per cent" reduction of that mortality in the present time, he would probably find it a far more difficult and perplexing one than he imagines

Perhaps the very latest treatise on croupous pneumonia from an authoritative source is the chapter on that subject in the third volume of the "System of Medicine by American Authors" just published, written by Alfred L Loomis, Professor of Practice of Medicine in the University of New York Under the head of *Prognosis*, Dr Loomis, after citing the ratio of mortality as reported by numerous recent writers, as derived from the hospitals of cities, the camps of armies and from private practice, sums up the result as follows "The mortality-average from *all the published reports to which I have had access*, gives 20 1 per cent of deaths" And he adds, "from such facts it must be admitted that a disease in which death occurs in one out of every five cases should be classed among the very fatal diseases But the death-rate varied very much at different times, *it is to-day the same as when Andral wrote, nearly fifty years ago* He stated that it varied from 33 to 2 per cent" It will be observed that the *fifty* years ago, when Andral wrote, was just the period when our contributor, Dr Hart, says the mortality was so *frightful and appalling* from the "blood-letting, purging" and other antiphlogistic measures then in vogue Yet his mortality results, instead of being from 250 to 500 per cent greater, are actually a little less than those obtained by Dr Loomis since J Hughes Bennett called his "halt" The highest rate of mortality mentioned by Andral was 33 per cent, while of 255 cases treated by Dr Loomis in his wards of the Bellevue Hospital during four years 87, or 34 per cent, died During the great war in this country from 1861 ,to 1865, of 61,202 cases of pneumonia reported as occuring among the white troops, 14,738 or a little more than 24 per cent died During the same period there occurred among the colored troops 16,133 cases, with a reported mortality of 33 per cent, or one in every three cases On the other hand, Sir J MacGregor states that of 4027 cases occurring among the troops in Spain, during the war with Napoleon, more than fifty years ago, 285 died, or only one in fourteen And the report adds, that they were treated "energetically," etc

Our sole object in calling attention to this subject, is to guard the younger portion of our readers against the adoption of such exaggerated ideas of the evil effects of former methods of treatment as compared with those popular at the present time, without first critically examining the literature of the past, as well as that of the present concerning any given topic under consideration

SOCIETY PROCEEDINGS

AMERICAN GYNECOLOGICAL SOCIETY

Tenth Annual Session, held at Washington, Sept 22, 23, and 24, 1885

(Concluded from page 468)

Second Day—Afternoon Session

In the discussion of Dr Reamy's paper, Dr H P C Wilson said that all agree that the perineum should be supported, but there is a great variety as to the way in which this support should be made Dr Reamy's method appears to be very practical, and it has the advantage of leaving the operator free to watch the case

Dr Mann thought the method of Dr Reamy a good one in a certain proportion of cases, but he was sure that he had seen some cases where it would have been of no avail The worst ruptures that he had seen had occurred in cases where, at the acme of the expulsive pain, the woman has torn herself from the accoucheur In such cases, the use of chloroform would of course obviate the difficulty Another objection to the method is that it requires more assistance than can always be secured

Dr Joseph Taber Johnson had made a few investigations in regard to the necessity of supporting the perineum at all, and he had found that perhaps more lacerations of the perineum occur in the practice of physicians who support the perineum, than in the practice of midwives who do not support the perineum

Dr Chadwick thought the term "supporting the perineum" a misnomer What is meant is retardation of the child's head, until the tissues can be sufficiently stretched to permit the passage of the head He does not permit the head to escape during a pain The method which he employs is to have the patient on her side and then pass one arm over the thigh, and by interlocking the fingers, he could make any desired amount of pressure The head is held back until the perineum is sufficiently stretched

Dr Ellwood Wilson, of Philadelphia, had tried all the methods that had been suggested for the support of the perineum, with the exception of the one described by Dr Reamy His usual plan is simply to instruct the woman to keep her mouth open during a pain

Dr Reamy, in replying to the statement of Dr Chadwick that supporting the perineum was a misnomer, said that the word support means protection or succor, and he used it in this sense The number of assistants required had been objected to, but the importance of preventing rupture of the perineum in the first labor is so great that even if two or three skilled assistants were required, they should be employed With this method the patient cannot get away An objection to the method referred to by Dr Chadwick is that the pressure is not made over the perineum, but over the head, and in the efforts to retard the head extension may be produced, causing the delivery of the head in a bad relation to the axis of the outlet The method mentioned obviates this By this method, the head can be retarded as much as may be desired He called attention to a clinical picture familiar to all, in which the head has been permitted to remain pressing on the perineum for from half an hour to two or three hours, until the perineum is stretched to the degree described in the paper The tissues are then in a state of beginning necrosis and exceedingly friable Even in such a case, the use of the towel or bandage lessens the perils of the perineum, and it will often be saved where otherwise it would have been torn It cannot be supported by the hand under such circumstances If it be desired, the forceps may be applied with the bandage in position

Dr E W Jenks reported

A CASE OF CÆSAREAN SECTION

He described the following case, which he had seen in consultation "The patient, aged 27, had given birth to one child five years previously without special difficulty, two years later, she received a fracture of the ilium from a building falling on her She was taken in labor at three o'clock in the morning The physician in attendance, finding some difficulty, tried to apply the forceps He got one blade on without difficulty, but could not, after several trials, introduce the second blade He sent for assistance, and the attempt to apply the forceps was again made without success The cause of difficulty was a projecting shelf of bone at the seat of fracture Another physician was called in, and the forceps were again tried It was then decided to perform craniotomy, which was done, but still the head could not be made to descend Dr Jenks was then sent for He tried to apply the forceps to make sure that they could not be applied, and failing, tried the cephalotribe with no better success It was then decided to perform abdominal section This was performed at two o'clock that night, twenty four hours after labor began The woman appeared to be in good condition The incision was made through the abdominal wall and the uterus opened The placenta was attached directly under the incision, and there was alarming hæmorrhage, which, however, was quickly checked by the rapid delivery of the fœtus The edges of the uterine incision were brought together by silk sutures, and the abdominal wound closed The patient did well until three days after the operation, when she suddenly died It was subsequently learned that the nurse had, in disobedience to orders, temporarily left the room, and in her absence the patient got out of bed She, complained of feeling something give way and experienced severe pain, and died in a few hours

Dr A J C Skene, of Brooklyn, thought that in such cases the chances of the patient are lessened by undue efforts at delivery by the forceps He thought that this would have been a good case for the performance of laparo elytrotomy It is impossible to sacrifice the child by that operation if it is performed in good time He could hardly imagine any case in which craniotomy should be performed, except, possibly, where the head is so engaged in a small inferior strait that it can be delivered in no other way Even then, he was not certain that the Cæsarean section would not be the best operation

Dr Jenks said that the operation of laparo-elytrotomy was discussed, but it did not seem to be an easy operation under the circumstances If it had not been for the unfortunate accident in this case, he thought that the woman would have recovered

Dr Ellwood Wilson, of Philadelphia, read a paper on

THE USE OF TARNIER'S FORCEPS

Dr Wilson had, at the meeting in 1881, read a paper in which he offered a number of objections to the use of these forceps His objections had been based on theoretical grounds The object of the present communication was to report nine cases in which he had used the forceps with decided advantage to the patient He had therefore modified his views A detailed account of the nine cases in which the forceps had been used was then given The instrument used had been Dr Howard's modification of Tarnier's forceps

Dr Neale, of Baltimore, exhibited his modification of the Tarnier forceps, which consisted in adapting the Tarnier principle to the Simpson forceps

Dr M D Mann had used the Tarnier forceps for the past two years in a number of cases, with satisfactory results in the main In one case of deformed pelvis in which the Tarnier forceps were applied, the child was finally delivered and the woman made a good recovery The child was, however, injured by the forceps The outer edge of the orbit had been crushed in, destroying the eye The child was living at the time of birth, but subsequently died

The President said that so far as he knew, he was the first one to use the Tarnier forceps successfully in America In cases of occipito-posterior positions he thought that the application of other forceps interfered with the rotation of the head, but with the Tarnier forceps the head is free to rotate

Evening Session

At the business meeting, the following were elected

OFFICERS FOR THE ENSUING YEAR

President, Dr Thad Reamy, Cincinnati

Vice Presidents, Dr Theophilus Parvin, of Philadelphia, and Dr George J Engelmann, of St Louis

Secretary, Dr Joseph Taber Johnson, Washington, D C

Treasurer, Dr Matthew D Mann, Buffalo

Other members of the Council, Drs Frank P Foster, B B Browne, J C Reeve, and R B Maury

New members were elected as follows "Dr J B Hunter, New York, Dr Charles Jewett, Brooklyn, and Dr W H Parrish, Philadelphia.

The next meeting will be held at Baltimore, Md , September 21, 22, and 23, 1886

THURSDAY, SEPTEMBER 24—THIRD DAY

DR R STANSBURY SUTTON of Pittsburg, read a paper on

A MODIFICATION OF EMMET'S CERVIX OPERATION IN CERTAIN CASES, WITH A CASE

He said that while the operation was original as far as he was concerned, he did not claim to be the only one who had performed it Cicatricial tissue is found to a greater or less extent in every lacerated cervix which has lasted for any length of time This is especially apt to be the case where nitrate of silver has been used in the treatment of the cervix The hardened tissue may be present in both lips, or it may be limited to one lip

The case reported was operated on June 5, 1885 She was the mother of several children There was a double laceration of the cervix The tissue of the anterior lip was hardened and hypertrophied, and the lip was convex from side to side and also from before backward, so that by the ordinary method of operation correct coaptation could not be effected The tissue of the anterior lip was as hard as cartilage Ordinary denudation of the posterior lip was sufficient, and this was made, leaving the strip of mucous membrane somewhat wider than usual The cicatricial mass involving the anterior lip was removed from border to border, completely denuding this portion of the cervix The parts were then brought together in the usual way, and the result was excellent The cervical canal readily admits a sound, and the woman menstruates without difficulty He thought that there were cases in which nothing short of the complete removal of the cicatricial tissue will be sufficient

DR WM GOODELL remarked that he had resorted to this device on more than one occasion He had done another thing on a few occasions, that is, outlined the strip of mucous membrane to be left and dissected it from the tissues below, leaving it united at its base The indurated tissue was removed and the flaps brought together The result was good

DR SKENE objected to the term cicatricial tissue as incorrect This was not cicatricial tissue, but a true sclerosis, a hypertrophied, indurated tissue Much could be done to get rid of this tissue by preparatory treatment But this often requires too much time, and then such an operation as that proposed by Dr Sutton was of service His own plan is to remove a transverse wedge shaped piece out of one or both lips of the cervix, as the case required, and then bring the surfaces together with silk stitches After the first day, the patient can go about, and the sutures are removed in the course of a week or ten days After the size of the cervix is reduced he performs the ordinary operation He had done both operations at one sitting, but preferred to do them separately One objection to the method of Dr Sutton was that it leaves cicatricial tissue

DR G J ENGELMANN had seen the condition referred to, very constantly In old and severe cases, it is impossible to retain the strip of mucous membrane He had at times entirely denuded both lips, and on some occasions had complete union, but the passage of a probe served to keep a canal open For the last few years, he has paid no attention whatsoever to this central strip A single piece of the carbolized silk thread with which the opening was closed, was inserted to keep the canal patulous A probe passed a few times after the removal of the sutures will dilate the opening The result of this operation has been good The union, the involution, and the restoration of the health of the patient have been perfect This operation has been done only in severe cases, and as far as he knew, none of these patients had conceived

DR M D MANN had tried the method described by Dr Sutton In only one case was it necessary to denude both surfaces To keep a patulous canal, he introduced a piece of small drainage tube The case did well

DR BAKER considered the retention of the mucous membrane as important He thought that the method of Dr Sutton, by leaving cicatricial tissue on one side of the canal, will tend to make the canal tortuous As a rule, if the patient is properly prepared, it will not be necessary to remove this hypertrophied tissue If this is not done, Emmet's operation can still be performed in the way described by Dr Skene Dr Baker prefers to do both operations at the same time It is then not necessary to introduce a suture to bring the edges of the transverse incision together Great care should be exercised in the introduction of substances between the two flaps

The PRESIDENT said that a few weeks before the death of Dr Sims he had seen Dr Harry Sims perform this operation in the presence of his father He inserted a glass tube that fitted so loosely that it had to be retained with a plug of cotton

DR SKENE thought that if denudation was practiced on both sides, stenosis would certainly follow

DR WILLIAM GOODELL, of Philadelphia, read a paper on

INFLAMMATION OF THE PAROTID GLANDS, FOLLOWING OPERATIONS ON THE FEMALE GENITAL ORGANS

He first referred to the close relation existing between the salivary organs and the genital organs of the adult, as shown in mumps and other conditions Parotid bubo seems particularly liable to follow ovariotomy, where septicæmia has taken place He had seen parotid bubo once in 173 cases of ovariotomies This was in a greatly emaciated woman from whom a tumor weighing eighty pounds was removed The patient had been twice tapped, once six weeks before the operation The second tapping was followed by septic poison, and the operation was performed as a last resort The patient did well until the ninth day, when the left parotid gland began to swell It suppurated and was opened The patient finally died on the twenty-second day after the operation

There is a transference of irritation to the parotid glands in which there is no evidence of septic poisoning Of this the author had seen three instances, twice after ovariotomy and once after oophorectomy In these cases the parotid complication did not influence the progress of the case Not one of these ended fatally He regarded the affection of the glands as sympathetic and not symptomatic

Within a short time he had operated on a lacerated cervix The operation was followed by free hæmorrhage, and in the second week the parotid glands began to swell This was succeeded by hysterical trismus, which lasted for some time The patient recovered

Dr Sutton stated that out of twelve ovariotomies he had lost one patient, and she died with the complication referred to in the paper The case did well until convalescence was reached, when one parotid gland began to swell This was followed by swelling of the other gland The temperature varied one or two degrees from the normal There was slight diarrhœa, no tympany, and no soreness A number of rose colored spots were found about the second week, over the abdomen and arm In the third week she became much worse The glands diminished in size, but the temperature ran up and she died He regarded the cases as septicæmic Others who saw the case considered it a well marked case of typhoid fever

Dr J T Johnson had seen this complication in one case of ovariotomy On the third or fourth day swelling of the parotid appeared There were the rose-colored spots referred to by Dr Sutton There was some fever, and the patient died on the sixth day

Dr Mann wished to put on record three cases which he had seen The first was a case of ovariotomy There were distinct symptoms of septicæmia, and the patient died before the glands suppurated The second case was one in which he had removed all the uterus above the internal os, and also the ovaries At the end of the first week one gland became swollen There was little fever The patient made a good recovery The third case was a boy who had received a penetrating wound of the abdomen Enlargement of the glands followed, but he made a good recovery

Dr Emmet added two cases of inflammation of the parotid glands Once it followed an operation for lacerated cervix, the patient recovering Once it followed an operation on a small vesico-vaginal fistula, the patient dying This is the only time he had seen death follow this operation

Dr Baker had seen the complication follow Tait's operation, the patient recovering

Dr Reamy had met with two cases One was after Tait's operation The glands did not suppurate, but the patient died the seventh day after the operation The second was a case of supra-vaginal hysterectomy, in which the uterus and both ovaries were removed The left gland became much enlarged, but did not suppurate The patient recovered

Dr James R Chadwick, of Boston, read a paper on

PERISTALSIS OF THE GENITAL TRACT, AND A NEW THEORY TO EXPLAIN RELAXATION OF THE VAGINAL OUTLET DURING LABOR

Some time ago he was called to see a primapara in labor He found the os slightly dilated and the vaginal outlet quite rigid Returning two hours later, the outlet was much relaxed, although the head had not escaped from the uterus On another occasion a woman with a bleeding fibroid tumor consulted him The examination revealed quite a small outlet Ergot was given to check the bleeding Later the patient returned and the outlet was found much relaxed This had occurred coincident with the occurrence of uterine contractions and the forcing down of the tumor Further investigation of this subject has led him to the conclusion that there is peristaltis action of the lower portion of the genital canal as well as of the fallopian tubes, and that it is to this that the relaxation of the outlet is largely due

Dr Goodell referred to a fact which seemed to bear out this idea, when after labor or abortion, a piece of membrane or placenta is retained, the cavity of the cervix is found funnel shaped, showing that the uterus is trying to force out the retained substance

Dr Theophilus Parvin, of Philadelphia, reported a case of

FACIAL PARALYSIS IN THE INFANT FROM THE USE OF THE OBSTETRIC FORCEPS

The following case was described A well proportioned woman, aged 30 years, had been in labor thirty-two hours, the first stage lasting twenty-four hours The only difficulty appeared to be want of strength in the uterine contractions The forceps were therefore applied and the child delivered The following day it was observed that one side of the face was paralyzed This was especially noticeable when the child cried There was no evidence of bruising from the forceps The paralysis disappeared in ten days without treatment

Dr Ellwood Wilson had seen such cases, and in every instance the paralysis had been on the right side This was attributed to the predominence of the left occipito anterior and the right occipito posterior positions Under such circumstances, one blade of the forceps would make pressure on the nerve

Dr Skene said that the differential diagnosis between facial paralysis from injury and facial paralysis from apoplexy is of importance, for apoplexy is not uncommon in new-born children Usually the diagnosis is readily made, but difficulty occurs in cases in which there is facial paralysis from injury associated with paralysis of the arm caused by violence in delivery He had seen such a case in consultation In this case it was of great importance to complete the labor quickly, and the shoulder had been injured in delivery, so that there was facial paralysis and paralysis of the arm on the same side At first there was no trace of contusion, but in a short time ecchymosis appeared and a favorable prognosis was given, which was verified

Dr Richardson remarked in most cases that he had seen the paralysis has been on the right side Once it resulted from the pressure of a bony tumor of the pelvis He had seen it where the forceps were applied to the after-coming head

The following papers were read by title

The Genu-Pectoral Posture in the Prolonged Nausea and Vomiting of Pregnancy, with cases, by Dr. H. F. Campbell, of Augusta, Ga., and *A Study of an Unusual Type of Puerperal Fever*, by Dr. Fordyce Barker, of New York.

A resolution expressing the sympathy of the Society with ex-President Dr. Albert H. Smith, in his sickness, was offered and adopted.

The officers for the ensuing year were then installed, and the Society adjourned.

CHICAGO MEDICAL SOCIETY

Stated Meeting, Oct. 5, 1885.

(*Continued from page 470.*)

DR. AUGUSTUS V. PARK read a paper on

LAPAROTOMY IN A CASE OF GUN-SHOT WOUND OF THE INTESTINES.

He said: M. S., a butcher-boy, aged 16, of slight build, formerly in poor but lately in good health, was shot on September 1st, 1885, at 3.30 P. M. A pistol ball of calibre 22, fired from a distance of forty-five feet, entered the abdomen at a point midway between the symphysis pubis and umbilicus, two inches to the left of the median line. The patient was removed in a farmer's spring wagon from the place where he was shot to his home, a distance of seven miles. A dressing was applied, and at 1 P. M., the next day, he was taken to the Michael Reese Hospital. The patient arrived nearly exhausted; his temperature was 100° F., pulse 130, weak and intermitting. His respirations were thirty, his abdomen tympanitic especially high on left side. There was no liver dullness, giving rise to a theory that the liver was crowded upward by extravasated blood. At 1.30 P. M., laparotomy was performed, the incision being made directly over the seat of the wound. We could not find any wound of the peritoneum, or where the ball passed through it. As the peritoneum was opened, decomposed blood rushed through the opening with great force. Blood and blood-clots which quickly formed were removed with sponges; the intestines were drawn out and examined for wounds. The first wound found was an abrasion, the ball not having entered the intestine. There was but little hæmorrhage, and the wound was closed by the interrupted cat-gut suture. The second wound, half-inch in diameter, opened directly into the intestine. A small mesenteric artery was found divided and tied. All hæmorrhage ceased. The wound was closed by interrupted suture; no further injury could be detected. The abdominal cavity was cleansed with a one per cent. solution of carbolic acid; the intestines were washed, carefully examined and returned. The abdominal incision was closed by two sets of sutures, the peritoneal surfaces were approximated and closed by continuous suture.

At 5.30 on the morning after the operation the patient died. Seven hours later an autopsy revealed commencing peritonitis, the small intestines being apparently agglutinated together. A few blood clots and a quantity of extravasated blood were found in the peritoneal cavity on the left side. A contused wound of the rectum was found near the sigmoid flexure, the ball being deflected from this position into the muscular tissue below, where it was found imbedded. This case justifies the opinion of various eminent surgeons that we cannot tell the direction the bullet takes from the position of the wound of entrance, or exit. From the conditions existing in this case, he was of the opinion the case would have terminated favorably had he been able to perform, with antiseptic precautions, laparotomy immediately after the injury.

DR. F. E. WAXHAM said that Dr. Park was entitled to a great deal of credit for presenting his paper and the specimen, because it is the report of a case which terminated unfavorably. He thought the chances of the patient would have been better if he had been allowed more quiet. His frequent removals must have loosened the blood clots and increased the hæmorrhage and prolonged the shock. If he had recovered he would have thought it almost miraculous, for it is one of the maxims of abdominal surgery to have complete and perfect quietude for the patient.

DR. R. TILLEY said the study of gun-shot wounds of the abdomen is interesting to every member of the profession, no matter in what particular direction his favorite studies may lead. Any one of us may find ourselves confronted with the responsibility associated with such cases when delay in action may be culpable. Relative to the case before us, he should not only not consider a recovery miraculous, but deem the conditions associated with it more favorable than, on the average, can be expected. One of the conclusions formulated by our President before the American Medical Association in Washington in 1884 is, in opening the abdomen to look for gun shot wounds, the incision should be in the median line, regardless of the bullet wound. This procedure certainly facilitates efficient inspection, but in the present case it was ignored. He regretted that the cause of failure of the operation has not been thrown into stronger relief, and he felt like asking the President, Dr. C. T. Parkes, to formulate the lessons he would draw from the failure of this operation. Of course, the case will go on record as one of operation after gun-shot wound of the abdomen associated with failure, and will tend to develop hesitation in the mind of the general practitioner about a class of cases which in his opinion, called for urgent, prompt operating.

DR. R. G. BOGUE said there were a few lessons to be learned from this case. One is the advantage which would follow an early operation, before the blood or fluid in the abdominal cavity decomposes. An operation should be made before the irritation from this source is severe. Another lesson is the necessity of a thorough exploration of the abdominal cavity for the purpose of discovering and removing any foreign substance which may be in it. It is necessary to control hæmorrhage, by opening the abdomen and having free access to every part of it.

DR. J. H. ETHERIDGE said that it will be noticed the pulse-rate was high after the operation, which lasted two hours. The question arises, if we cannot account for death on the opinion that it was due to the action of the ether on the cardiac nervous system Was there acute poisoning from ether? Or, was death caused by septicæmia? He wished to thank Dr Park for the report of this case, because it is from the reporting of these unsuccessful cases we obtain the most benefit He did not believe it would deter any one from doing abdominal surgery, as it had already taken such a rank that the report of one unsuccessful case would not intimidate any surgeon, but enable him to steer clear of difficulties others may have encountered

The PRESIDENT said that he felt somewhat diffident about making any remarks, because his experience in connection with gun shot wounds of the abdomen was solely in connection with the results of experiments upon the lower animals "There is one fact demonstrated by this case, and it stands out in all the cases, of which I know, operated upon in man, which corroborates the results of the experiments made by myself, and that is, the necessity of free incision through the median line of the abdomen, without any reference to the course of the bullet, as the best way to get at the injury so as to determine its extent, and to apply the means of repair as well as to secure a clean abdomen Another item mentioned in the case, is the one that blood flowed freely from the bullet wound, while the pafient was in the erect position and ceased when he was recumbent As the bullet passed through parts of little vascularity, this item points to the wounding of some large vessel internally (as was found), and becomes a point of value in the question of perforation This question of perferation is no easy one to settle positively, even in the best of hands I am inclined to agree with Dr Waxham in the opinion that it was not the best plan to remove the patient from his home before operating, notwithstanding his bad surroundings We must take into consideration the fact that his patient was accustomed to his surroundings, and far less likely to be harmfully affected by them than by the danger incidental to the jolting movements of removal

"Some of the accidents of the case I am sure would have been avoided by obeying the rule of open incision in the median line The autopsy showed considerable old blood in the cavity, this would have been found and removed The paper states no extravasation of bowel contents was noticed, the non-existince of such condition has doubt thrown upon it by the condition found at the autopsy The wound in the rectum would have been discovered, and the action of the bowel displayed shows an untouched perforation of its walls, probably the wound of entrance of the bullet The exit wound is sewed up

"The manner of closing the external incision as well as the bowel wounds should be such as to *save time* in the operation, by using the continuous catgut suture for small bowel wounds and single through and through suture of the abdominal incision It is pure waste of time to unite the latter in layers

"It is a matter of some pride and great pleasure to me to know that the principles enunciated by me as the results of experiments on the lower animals (especially as they are ridiculed by some) have so recently been put to a severe but successful application upon the human body Dr Bull, of New York, had a successful case of nine perforations, and Dr J B Hamilton, of Washington, D C, also a successful case with eleven perforations In Dr Hamilton's case, the only bad happening arose from the formation of a blood tumor—probably, as Dr Hamilton says, forming from a grazed surface, the bleeding from which could not be counteracted This was subsequently opened through the rectum and the patient recovered But it is interesting to notice that the patient was in greater danger of his life from this mass of blood than from the wounds in the intestine after they had been closed It shows also how necessary it is to prevent bleeding by securing, if possible, all bleeding points"

CHICAGO GYNECOLOGICAL SOCIETY

Regular Meeting, Friday Evening, September 18th, 1885

THE PRESIDENT, H P MERRIMAN, M D,
IN THE CHAIR

DR E C DUDLEY made some remarks relative to his observations in

GYNECOLOGICAL AND ABDOMINAL SURGERY IN EUROPE

His observations were confined to the work of a few operators in England, Scotland and Heidelberg

In Heidelberg Dr Dudley inspected the hospital and saw evidence of considerable work in abdominal surgery Dr Kehrer's laboratory gave evidence of active research into gynecological bacteriology His work bore the stamp of thoroughness and efficiency Dr Kehrer is a medium-sized man frail and delicate, with a large head and small body

A call upon Dr Bantock, at his office, No 18 Harley Street, W, London, resulted in a pleasant hour's conversation upon subjects pertaining to ovariotomy and hysterectomy Patients at the Samaritan Hospital sometimes die within twenty-four hours after laparotomy, with a high temperature This condition was called acute sepsis by certain systematic writers Dr Bantock thought the true pathology of the condition was unknown, and was not satisfied with the term acute sepsis Dr Dudley saw Dr Bantock operate at the Samaritan Hospital The first operation was the removal of a small, solid ovarian tumor The remaining ovary and tube, although normal, were removed on account of a small intramural, uterine fibroid The striking feature of the operation was great rapidity without haste Dr Bantock caught up the edges of the peritoneum with small compression forceps, so that these edges were drawn up towards the cutaneous edges, and were held in this position by the weight of the instrument against the abdominal surface This manœuvre greatly facilitated the passage of the sutures The pedicle was secured by means of silk ligature, applied in the operator's peculiar figure-of eight turns

In closing the wound, a needle of ovoid shape, curved on the edge, instead of on the flat, was employed This needle combines the maximum of strength with the minimum of size Two or three sutures were passed through at each angle of the wound Their ends were joined by knots An assistant, passing the index finger of each hand through the loops thus formed, made traction at each angle of the wound, in such a manner as to draw its sides into contact, and to lift the peritoneal edges nearer to the surface The introduction of the remaining sutures was in this manner greatly facilitated The sutures were so closely passed that no superficial stitches were required They were made to include a very narrow margin of skin and peritoneum, and very little if any muscular tissue Fine silk-worm gut was employed

The ends of the sutures, on each side of the wound, were now grasped in lock forceps, which prevented them from being drawn out, or becoming tangled during the separation of the wound for the toilet of the peritoneum (which was most thorough), the entire cavity being rendered perfectly clean and dry The lock forceps were then removed from the ends of the sutures, and the hands of the assistant substituted The action was thus made on all the sutures, in the direction of the upper angle of the wound, and they were tied in order from below upward and cut short This prevents tangling of the threads and otherwise facilitates tying Antiseptics, throughout the operation, were conspicuous by their absence The dressings were of the most simple character

Dr Bantock showed Dr Dudley over the hospital, which contained a number of convalescents from hysterectomy, ovariotomy, and oophorectomy Dr Bantock's exceptionally good results, in the last operation, are recognized throughout the world His wonderful statistics in abdominal surgery are due to downright splendid operating Dr Meridith, at the same time, was removing a tumor in another room, under the most extreme antiseptic conditions The famous Samaritan Hospital is an unpretentious building, seemingly a large reconstructed dwelling, in the middle of a block, with houses joining on either side, and, like great men, has a modest appearance

It is generally supposed in America that the Woman's Hospital, in the State of New York, established by Marion Sims in 1855, was the first of its kind in the world This is a mistake Dr Sims himself, in a letter to Dr Protheroe Smith, of London, dated July, 1883, accords to that gentleman the honor of having established the first hospital specially for the treatment of the diseases of women This hospital, founded in 1842, is now a flourishing institution in London, and is called the Hospital for Women Its venerable founder visited Chicago a year ago His enthusiasm for the specialty in which he has been a pioneer continues, indeed, seems to increase with advancing years He retains his official connection with the institution, as senior physician, and is still engaged in active practice He was among the first, against bitter opposition, to advocate anæsthesia in labor Efforts are now being made, with great promise of success, to raise funds for the construction of a larger and more appropriate hospital building

Dr Dudley visited Birmingham, in response to a polite telegraphic invitation from Mr Lawson Tait On the train he occupied the same compartment with a sleek, well fed, high church London clergyman of the most conservative order, who intimated in no uncertain manner that the conservative people of London looked down upon the inhabitants of the radical city of Birmingham as a semi-barbarous community So decided were his denunciations of the radical party in general and of Birmingham in particular, which, as the chief stronghold of radicalism, always return John Bright and Chamberlain to Parliament, that Dr Dudley, in an apologetic manner, explained that he was only going into the jaws of the Philistine to witness an operation by a distinguished surgeon, from whom he hoped to learn something The clergyman inquired who the surgeon was, and upon hearing the name of Lawson Tait, exclaimed "O, I know all about him, he is just as bad as any of them," which means that Mr Tait is a radical in politics, as he is in surgery

Mr Tait's ridicule of antiseptics is well known His rapid method of operating conveys to the casual observer the idea of haste and almost of carelessness But closer observation very soon shows him to be one of those rare operators, where dexterity amounts almost to a sleight of hand An ovariotomy, in his hands, does not impress the observer as a capital operation It seems almost as trivial as opening an abscess His methods of operating did not materially differ from those of Dr Bantock In closing the wound he used but one needle, threaded with a piece of long silk, introducing this as if for a continuous suture, but did not draw the thread tight After the introduction of the needle, he left a long loop before the reintroduction Then, after taking the last stitch, he lifted the free loops of silk on the index finger, and severed them with the scissors, thereby converting the continuous into an interrupted suture These were tied in the ordinary way, and the wound was dressed in a manner which would be eminently acceptable to his most bitter antiseptic enemy

During the day Mr Tait performed ovariotomy, lumbo colotomy, perineorrhaphy, and excised a urethro-vulvar cyst, besides attending to a large number of consultations, in one of which Dr Dudley accompanied him to a distance of forty miles This was for him only a moderate day's work It is indeed evident that no other man in England controls a larger practice in abdominal surgery

During a brief visit in Edinburgh, Dr Dudley was pleasantly entertained by Dr Thomas Keith, who had just returned from a consultation with Dr Homans, in Boston, but unfortunately Dr Keith did not operate during this time, although a large number of patients were waiting for him at the Royal Infirmary His son, Dr Skene Keith, kindly invited Dr Dudley to an ovariotomy, his forty-eighth operation Up to this time he had only lost one or two patients His operation presented some interesting peculiarities He used probe pointed scissors of a peculiar pattern, instead of the director, in going down through the deeper layers of the abdominal walls By pressing firmly against the adhesions with a sponge, at the point of their attachment to the cyst, he literally sponged them away from the tumor It was surprising to note the facility with which rather firm adhesions were thus broken It is much easier to tear them from the tumor with the sponge than to tear the tumor from the adhesions The breaking of the adhesions in this way is also much more gentle, and, in the opinion of Dr Keith, diminishes the danger from shock The adhesions were ligatured with fine cat gut as fast as they were divided In passing the ligatures a forceps, similar to the ordinary compression forceps, was used This instrument had blades more than an inch long, of very small diameter terminating in sharp points, so sharp that when the blades were closed they could be thrust through any soft tissue like a large needle Grasping the ligature in the point of these blades, the tissue to be ligatured was transfixed The ligature was then pulled through and the forceps withdrawn The pedicle was transfixed and ligatured, with fine silk, in the same way

The cautery, to which much of the elder Keith's success has been attributed, was not employed in this case, because the pedicle was very slender The reason why the cautery, in the hands of other operators, has not proved a more perfect protection against hæmorrhage, becomes apparent to any one who has witnessed its application in the hands of Dr Keith The whole secret of his method is, first, in the powerful compression of the pedicle between the broad blades of a heavy Baker Brown clamp, second, in the prolonged application of the red hot cautery iron, not only to the pedicle, but, after this has been burned to the level of the clamp, also to the clamp itself In this way the clamp becomes so hot that the included portion of the pedicle is slowly and thoroughly cooked, so that when the instrument is removed, the end of the pedicle is thin and translucent, resembling a horny substance Such a pedicle, in the experience of Dr Keith, never gives trouble from oozing The wound was closed with fine silk sutures which had been boiled Ten or fifteen pieces of silk were threaded at each end with very finely, well-tempered needles nearly three inches long, which were introduced on either side from within outward Very small margins of peritoneum and skin were included in the sutures Dr Keith thought it a very common fault among operators to draw the stitches too tight in tying The long, fine needle used in closing the wound is superior It makes a very small puncture, which never bleeds, and is so fine that it is easily pushed through by means of finger and thumb without needle forceps In the *American Journal of Obstetrics*, April, 1880, Marion Sims had given a remarkable description of the Keith operation, which has exerted a powerful and beneficent influence upon the operation in America Dr Dudley could add little except the gentle handling of the adhesions with the sponge, the ligature forceps, and the peculiar long, straight needles already mentioned

The wonderful success without antiseptics recorded by the great Scotch ovariotomist, by Dr Bantock and by Mr Tait, who have reduced the mortality almost to zero, must have great influence in fixing the value of Listerism so far as it relates to abdominal surgery At any rate, incompetent operators can no longer venture with impunity upon these capital operations under the dangerous impression that, in some mysterious way, antiseptics will deprive a crude surgical performance of its greatest perils Evidently it was not so much a question of Listerism as of removing the tumor with the least possible amount of operating, and in the shortest time consistent with careful attention to detail, and in the most gentle manner Dr Dudley, however, raised the pertinent question whether Listerism should be placed on trial before a court of abdominal surgeons, and whether, if found unnecessary in peritoneal surgery, it could be fair to condemn it in general He thought such a verdict could not be sustained by the facts, but that the antiseptic principle in surgery was destined to stand Even the most violent opponents of antiseptics agreed that perfect cleanliness was essential He knew of no other method by which cleanliness could be rendered so nearly absolute Nor did the seeming ability of two or three of the most dexterous operators to do without antiseptics prove that it might not be a useful aid to others Clearly, the man who removes a tumor with the least operating and handling of the parts will require fewer preventive measures against inflammation and sepsis Antiseptics, therefore, might be most valuable for an inexperienced operator, and, to say the least, an additional safeguard for any one Some American operators were now having about as good results as could be shown in Great Britain, which seemed to indicate that our former high mortality in this American operation had been due in reality to bad operating, and not, as many supposed, to climatic causes

The minor gynecology of Great Britain had apparently made but little progress since the days of Bennett and Simpson The general impression prevails that on this side of the Atlantic we are going wild in the minor gynecological surgery In response, we may now congratulate our English brethren that many of their leading gynecologists are already commencing to comprehend, to appreciate and to perform the American operations of perineorrhaphy, elytrorrhaphy and trachelorrhaphy, and at the same time to lay aside, in a measure, the old *porte caustique*

Dr H P Newman said that there were other reasons for the brilliant success of foreign laparotomists than those referred to by Dr Dudley Aside from the facility and expeditious manner of operating, acquired by large experience, a prime factor is the justifiable self confidence of the operator and a responsive confidence inspired in the patient

Dr W W Jaggard thought that minor gynecological operations, as Dr Dudley termed them, were less frequent in the United Kingdom and the Continent than in America Dr Dudley had made this general assertion, and he agreed with him He did not, however, think the operative skill of British or Continental surgeons inferior to that of their American *confreres* The indications for operative procedure do not exist in the United Kingdom and the Continent as in America Laceration of the cervix and perineum are of much less frequent occurence The ployed This needle combines the maximum of strength with the minimum of size Two or three sutures were passed through at each angle of the wound Their ends were joined by knots An assistant, passing the index finger of each hand through the loops thus formed, made traction at each angle of the wound, in such a manner as to draw its sides into contact, and to lift the peritoneal edges nearer to the surface The introduction of the remaining sutures was in this manner greatly facilitated The sutures were so closely passed that no superficial stitches were required They were made to include a very narrow margin of skin and peritoneum, and very little if any muscular tissue Fine silk worm gut was employed

The ends of the sutures, on each side of the wound, were now grasped in lock forceps, which prevented them from being drawn out, or becoming tangled during the separation of the wound for the toilet of the peritoneum (which was most thorough), the entire cavity being rendered perfectly clean and dry The lock forceps were then removed from the ends of the sutures, and the hands of the assistant substituted The action was thus made on all the sutures, in the direction of the upper angle of the wound, and they were tied in order from below upward and cut short This prevents tangling of the threads and otherwise facilitates tying Antiseptics, throughout the operation, were conspicuous by their absence The dressings were of the most simple character

Dr Bantock showed Dr Dudley over the hospital, which contained a number of convalescents from hysterectomy, ovariotomy, and oophorectomy Dr Bantock's exceptionally good results, in the last operation, are recognized throughout the world His wonderful statistics in abdominal surgery are due to downright splendid operating Dr Meridith, at the same time, was removing a tumor in another room, under the most extreme antiseptic conditions The famous Samaritan Hospital is an unpretentious building, seemingly a large reconstructed dwelling, in the middle of a block, with houses joining on either side, and, like great men, has a modest appearance

It is generally supposed in America that the Woman's Hospital, in the State of New York, established by Marion Sims in 1855, was the first of its kind in the world This is a mistake Dr Sims himself, in a letter to Dr Protheroe Smith, of London, dated July, 1883, accords to that gentleman the honor of having established the first hospital specially for the treatment of the diseases of women This hospital, founded in 1842, is now a flourishing institution in London, and is called the Hospital for Women Its venerable founder visited Chicago a year ago His enthusiasm for the specialty in which he has been a pioneer continues, indeed, seems to increase with advancing years He retains his official connection with the institution, as senior physician, and is still engaged in active practice He was among the first, against bitter opposition, to advocate anæsthesia in labor Efforts are now being made, with great promise of success, to raise funds for the construction of a larger and more appropriate hospital building

Dr Dudley visited Birmingham, in response to a polite telegraphic invitation from Mr Lawson Tait On the train he occupied the same compartment with a sleek, well fed, high church London clergyman of the most conservative order, who intimated in no uncertain manner that the conservative people of London looked down upon the inhabitants of the radical city of Birmingham as a semi barbarous community So decided were his denunciations of the radical party in general and of Birmingham in particular, which, as the chief stronghold of radicalism, always return John Bright and Chamberlain to Parliament, that Dr Dudley, in an apologetic manner, explained that he was only going into the jaws of the Philistine to witness an operation by a distinguished surgeon, from whom he hoped to learn something The clergyman inquired who the surgeon was, and upon hearing the name of Lawson Tait, exclaimed "O, I know all about him, he is just as bad as any of them," which means that Mr Tait is a radical in politics, as he is in surgery

Mr Tait's ridicule of antiseptics is well known His rapid method of operating conveys to the casual observer the idea of haste and almost of carelessness But closer observation very soon shows him to be one of those rare operators, where dexterity amounts almost to a sleight of hand An ovariotomy, in his hands, does not impress the observer as a capital operation It seems almost as trivial as opening an abscess His methods of operating did not materially differ from those of Dr Bantock In closing the wound he used but one needle, threaded with a piece of long silk, introducing this as if for a continuous suture, but did not draw the thread tight After the introduction of the needle, he left a long loop before the reintroduction Then, after taking the last stitch, he lifted the free loops of silk on the index finger, and severed them with the scissors, thereby converting the continuous into an interrupted suture These were tied in the ordinary way, and the wound was dressed in a manner which would be eminently acceptable to his most bitter antiseptic enemy

During a brief visit in Edinburgh, Dr Dudley was pleasantly entertained by Dr Thomas Keith, who had just returned from a consultation with Dr Homans, in Boston, but unfortunately Dr Keith did not operate during this time, although a large number of patients were waiting for him at the Royal Infirmary His son, Dr Skene Keith, kindly invited Dr Dudley to an ovariotomy, his forty eighth operation Up to this time he had only lost one or two patients His operation presented some interesting peculiarities He used probe pointed scissors of a peculiar pattern, instead of the director, in going down through the deeper layers of the abdominal walls By pressing firmly against the adhesions with a sponge, at the point of their attachment to the cyst, he literally sponged them away from the tumor It was surprising to note the facility with which rather firm adhesions were thus broken It is much easier to tear them from the tumor with the sponge than to tear the tumor from the adhesions The breaking of the adhesions in this way is also much more gentle, and, in the opinion of Dr Keith, diminishes the danger from shock The adhesions were ligatured with fine cat-gut as fast as they were divided In passing the ligatures a forceps, similar to the ordinary compression forceps, was used This instrument had blades more than an inch long, of very small diameter terminating in sharp points, so sharp that when the blades were closed they could be thrust through any soft tissue like a large needle Grasping the ligature in the point of these blades, the tissue to be ligatured was transfixed The ligature was then pulled through and the forceps withdrawn The pedicle was transfixed and ligatured, with fine silk, in the same way

The cautery, to which much of the elder Keith's success has been attributed, was not employed in this case, because the pedicle was very slender The reason why the cautery, in the hands of other operators, has not proved a more perfect protection against hæmorrhage, becomes apparent to any one who has witnessed its application in the hands of Dr Keith The whole secret of his method is, first, in the powerful compression of the pedicle between the broad blades of a heavy Baker Brown clamp, second, in the prolonged application of the red hot cautery iron, not only to the pedicle, but, after this has been burned to the level of the clamp, also to the clamp itself In this way the clamp becomes so hot that the included portion of the pedicle is slowly and thoroughly cooked, so that when the instrument is removed, the end of the pedicle is thin and translucent, resembling a horny substance Such a pedicle, in the experience of Dr Keith, never gives trouble from oozing The wound was closed with fine silk sutures which had been boiled Ten or fifteen pieces of silk were threaded at each end with very finely, well tempered needles nearly three inches long, which were introduced on either side from within outward Very small margins of peritoneum and skin were included in the sutures Dr Keith thought it a very common fault among operators to draw the stitches too tight in tying The long, fine needle used in closing the wound is superior It makes a very small puncture, which never bleeds, and is so fine that it is easily pushed through by means of finger and thumb without needle forceps In the *American Journal of Obstetrics*, April, 1880, Marion Sims had given a remarkable description of the Keith operation, which has exerted a powerful and beneficent influence upon the operation in America Dr Dudley could add little except the gentle handling of the adhesions with the sponge, the ligature forceps, and the peculiar long, straight needles already mentioned

The wonderful success without antiseptics recorded by the great Scotch ovariotomist, by Dr Bantock and by Mr Tait, who have reduced the mortality almost to zero, must have great influence in fixing the value of Listerism so far as it relates to abdominal surgery At any rate, incompetent operators can no longer venture with impunity upon these capital operations under the dangerous impression that, in some mysterious way, antiseptics will deprive a crude surgical performance of its greatest perils Evidently it was not so much a question of Listerism as of removing the tumor with the least possible amount of operating, and in the shortest time consistent with careful attention to detail, and in the most gentle manner Dr Dudley, however, raised the pertinent question whether Listerism should be placed on trial before a court of abdominal surgeons, and whether, if found unnecessary in peritoneal surgery, it could be fair to condemn it in general He thought such a verdict could not be sustained by the facts, but that the antiseptic principle in surgery was destined to stand Even the most violent opponents of antiseptics agreed that perfect cleanliness was essential He knew of no other method by which cleanliness could be rendered so nearly absolute Nor did the seeming ability of two or three of the most dexterous operators to do without antiseptics prove that it might not be a useful aid to others Clearly, the man who removes a tumor with the least operating and handling of the parts will require fewer preventive measures against inflammation and sepsis Antiseptics, therefore, might be most valuable for an inexperienced operator, and, to say the least, an additional safeguard for any one Some American operators were now having about as good results as could be shown in Great Britain, which seemed to indicate that our former high mortality in this American operation had been due in reality to bad operating, and not, as many supposed, to climatic causes

The minor gynecology of Great Britain had apparently made but little progress since the days of Bennett and Simpson The general impression prevails that on this side of the Atlantic we are going wild in the minor gynecological surgery In response, we may now congratulate our English brethren that many of their leading gynecologists are already commencing to comprehend, to appreciate and to perform the American operations of perineorrhaphy, elytrorrhaphy and trachelorrhaphy, and at the same time to lay aside, in a measure, the old *porte caustique*

Dr H P Newman said that there were other reasons for the brilliant success of foreign laparotomists than those referred to by Dr Dudley Aside from the facility and expeditious manner of operating, acquired by large experience, a prime factor is the justifiable self-confidence of the operator and a responsive confidence inspired in the patient

Dr W W Jaggard thought that minor gynecological operations, as Dr Dudley termed them, were less frequent in the United Kingdom and the Continent than in America Dr Dudley had made this general assertion, and he agreed with him He did not, however, think the operative skill of British or Continental surgeons inferior to that of their American *confrères* The indications for operative procedure do not exist in the United Kingdom and the Continent as in America Laceration of the cervix and perineum are of much less frequent occurence The *cervix uteri* is usually effaced, and the external os is fully dilated before the application of the forceps Manual dilatation is less frequently practiced The bag of waters is not prematurely ruptured Greater care is taken with the preservation of the perineum In a word, obstetricians are better operators, and do not require so called gynecological assistants

Dr E J Doering said that in 1874, he had been present at ovariotomy and other operations, performed at the Samaritan Hospital by Sir Spencer Wells He was particularly impressed with the extreme care exercised in admitting spectators to the operations, each visitor being required to sign a statement that he had not made an autopsy or attended a case of contagious disease for the two or three days preceding He desired to know whether these regulations were still in force, and also if Mr Lawson Tait and Dr Keith required similar restrictions

The President asked the following questions 1 Was any treatment given to the patients to prepare them for the operation by any of the eminent gentlemen mentioned? 2 How were the patients covered during the operation, or was the whole abdomen left bare? 3 How was the evacuation of the cyst managed? 4 Was the patient turned upon her side to accomplish this, as Dr Thomas sometimes does?

The President suggested that all who desired should ask questions for further light before the general discussion began

Dr Christian Fenger replied to the question, raised by Dr Dudley, that antiseptic precautions might be more important in surgery, in general, than in abdominal surgery, where it looked as though more perfect methods of operating without antisepsis gave as good results as with antisepsis, as follows

He thought that the abdominal, or rather peritoneal cavity, in respect to the antiseptic precautions, occupies a peculiar position in surgery The danger from absorption of the poisonous antiseptics is far greater in the abdomen than in wounds The ability of the peritoneum to absorb serous fluid and blood before it decomposes, to encapsulate foreign substances not capable of absorption—*ex gr*, rubber ligature—is perhaps somewhat greater than the ability of a wound in that direction, although it may be that there is some prejudice about this, as we have not as yet used silk ligatures extensively in general surgery As to the question, whether more perfect methods of operating without antisepsis would improve the results, or rather prevent inflammation and sepsis, he could say that outside of the peritoneum this question must as yet be answered in the negative

In 1873, Volkman, of Halle, introduced the Lister method of dressing and operating in his surgical clinics In his report of the work done in 1873 (*Beitrage zur Chirurgie*, 1875), the antiseptic surgery had reduced inflammatory and septic complications following excisions, amputations, fresh penetrating articular wounds, fresh open fractures, to a minimum never before dreamt of, and all this in one year In the broad field of surgery it is not possible that Volkmann or anybody else could improve the *technique* of operating, to the extent of having the results change all of a sudden in that way No surgeon would dare, to day, to excise, for example, a knee-joint, without antiseptic precautions in all the minute details, even if he employed all the latest improvements in the method of operating Abdominal surgery is the only branch of surgery in which, as yet, the heavy operating has been done without antiseptic precautions

---

GYNECOLOGICAL SOCIETY OF BOSTON

Stated Meeting, June 11, 1885

The President, H O Marcy, M D, in the Chair

Dr I S Fox, of Lowell, reported

TEN CASES OF ABDOMINAL SECTION

As regards the *modus operandi*, the minimum incision should be made, unless the tumor is solid or firmly adherent Before tapping the cyst, the patient is turned upon the right side, and the sac drawn forward as the fluid escapes If the bulk of the tumor remains, enlarge the opening into the sac, turn their lateral edges out over the lips of the incision, pass in the hand and break up remaining cysts The sac having been extricated, the patient is placed on her back and the pedicle secured As a ligature, coarse, loosely-braided silk is used, as ordinary silk cuts the soft tissues and causes troublesome hæmorrhage

The sac having been cut away, the peritoneal edges of the stump are brought together and overcast with catgut The abdominal cavity is carefully sponged out and the bleeding point secured The abdominal wound is thoroughly cleansed and covered with oiled silk, over which a padding of antiseptic gauze is placed This dressing is kept in place by long strips of adhesive plaster All silk used is previously boiled and kept in water All water used is boiled A solution of carbolic acid is used in spraying room and mopping floor On day before operation patient is bathed in weak carbolized water, and vaginal douche of same liquid used Temperature of room should be from 68° to 72° Fahr

Dr Fox suggested a change in Keith's drainage tube, which consisted of a constriction just below the flange to assist in holding it in position

Cases 1, 2 and 3 were cases of multilocular cysts weighing eighteen, twenty-seven and thirty-five lbs respectively Recovery in each case

Case 4—Patient 43 years old, and extremely weak and emaciated Pulse rapid, feet moist, œdematous and cold Diagnosis cystoma complicated with uterine fibroid Tumor removed weighed twenty-seven lbs Recovery

Case 5—Multilocular cyst weighing twenty lbs was removed Extensive adhesions Septic peritonitis on fourth day By use of quinine, alcohol and opium patient recovered after a lingering illness

Case 6—Age, twenty seven Always delicate and subject to glandular swellings about neck Before she decided to submit to an operation, pregnancy supervened She presented herself for operation when five months pregnant Cyst crowded upward by impregnated uterus Cyst removed weighed fifteen lbs Miscarried on fifth day Temperature remained at 99° for three days, when lochia became offensive and patient had chills Left parotid increased to an enormous size and was extremely painful Temperature rose to 104° Fahr , and patient seemed in a critical condition Intra uterine douche of two and one-half per cent was used at a temperature of 105° All the unpleasant symptoms subsided within a week

Case 9 —Patient 27 years old For eight years had suffered agonizing pains through pelvis, always referable to one or both ovaries At first these pains took the form of dysmenorrhœa, and incapacitated her for work for two weeks out of the four During past three years pains had come on without reference to menses Often they were accompanied by vomiting which lasted for days at a time She was much emaciated Latterly her sufferings could be palliated only by the use of anæsthetics All treatment, including galvanism, failed After consultation, removal of ovaries was allowed and eagerly accepted Operation was performed two months ago, and thus far entire relief has been obtained Ovaries were non adherent and of normal size, but studded with small cysts

Case 10 —Patient 41 years old For two years had had menorrhagia and was unwell the greater part of the time Diagnosis fibroma of uterus and cystic tumor of right ovary Operation performed and small cyst removed Small pedunculated fibroid was removed from back of uterus Left ovary was so firmly held by fibroid uterus that it was impossible to remove it Recovery

Dr W S Brown thought the paper complete, and asked about the silk used Dr Brown prefers black silk, as it is dyed with iron and is innocuous, it can also be more readily seen in the tissues White or yellowish silk is prepared by the use of acetate of lead

Dr Fox stated that the silk used by him was made by Hepner, of New York, and was so coarse and loosely braided as not to cut the tissues and cause troublesome hæmorrhage

In response to questions from members of the Society, Dr Fox made the following statement Fluid accumulations in the abdomen might be mistaken for ovarian cysts by experienced men A case once operated on by Dr Kimball, of Lowell, illustrated this fact Patient had had Potts' disease and spinal curvature, but had never been confined to bed Abdomen increased in size for three years Pulse and temperature normal Operation for ovarian cyst was performed and a pailful of pus removed Sac adherent to spine and could not be removed Lived sixteen days The autopsy showed an immense psoas abscess on left side and smaller one on right Cases of spontaneous cure have been reported, but the tendency is toward a fatal issue, therefore Dr Fox usually operated as soon as diagnosis was certain Does not consider the character of the fluid before operating He does not believe in Drysdale's corpuscles

Dr A P Clarke thought that the marked fatality of the earlier cases operated on was due to the fact that the operation was deferred until the last stages of the disease

Dr W S Brown was often in doubt as to the proper time for operation Has a case now under observation in which the tumor is of the size of a man's head When discovered five years ago it was of size of pigeon's egg No unpleasant symptoms exist except prolapse of uterus Suspects it is a tumor of broad ligament As a rule, parovarian tumors grow slowly and ovarian tumors rapidly Dr Brown called attention to the fact that Sir Spencer Wells has discovered by a careful study of the history of cases subsequent to operation, that many of them die within three or four years

DOMESTIC CORRESPONDENCE

NEW YORK LETTER

(FROM OUR OWN CORRESPONDENT)

First Annual Meeting of the Fifth District Branch —Electrolysis in Surgery—Fracture of the Skull with Depression—Poisoning by Aniline Oil—Causation and Treatment of Coryza—Cirrhosis of the Lungs—Surgical Practice and Surgical Anatomy—Treatment of Varicocele—The Approaching Meeting of the State Medical Association

The first annual meeting of the Fifth District Branch of the New York State Medical Association was held at the Mansion House, Brooklyn, on the 13th of October, and despite the fact that it chanced on the stormiest day of the season, was extremely successful There were two sessions, one in the morning and one in the afternoon, and the first scientific paper at the former was by Dr Robert Newton, of New York, on the subject, "*Progress of Electrolysis in Surgery* " Having spoken of the paper which he read before the American Medical Association in 1883, on "Electrolysis in Surgery, with Tabular Statistics of One Hundred Cases of Urethral Stricture," which was afterwards published in two parts, the first in the Journal of the Association, April 25, 1885, and the second in the *New England Medical Monthly* for August, 1885, he said that the object of the present paper was to relate what has been done in surgical electrolysis within the last two years, or since the date of the former paper During this period some good work had been done by reliable men, which confirmed the reports of previous experience with the method The only entirely new application of it appeared to be that of Dr Craft, of Cleveland, Ohio, a member of the American Medical Association, to the treatment of hernia and hemorrhoids The radical cure of hernia by electrolysis was new and original, and in a private letter to Dr Newman, Dr Craft stated that to accomplish this he had applied a positive needle electrode, properly insulated, except at the point, subcutaneously, between the external and internal rings, and allowed a sufficient galvanic current to pass behind the poles to excite adhesive inflammation, being careful not to injure the cord and to keep the needle external to the peritoneum This resulted in a cicatricial sealing up of the inguinal canal, and, in many cases, seemingly permanently Having described Dr Craft's method of treating hæmorrhoids by electrolysis, he went on to speak of the successful application of the procedure in aneurism of the aorta by Dr Francesco Brancaccio, of Naples, in port-wine marks by Dr W A Hardaway, of St Louis, and others, for the purpose of removing superflous hair by Dr C Heitzman, in uterine tumors by Dr J N Freeman, of Brooklyn, Dr J T Everett, of Clyde, Ohio, and Drs Apostolé and Méniere, of Paris, in stricture of the Eustachian tube by Mons Mercier and Garricon-Desarenes, of Paris, and in stricture of the œsophagus by Professor H'jorth, of Christiania

In reply to a question by Prof Wm H Pancoast, of Philadelphia, who was present at the meeting by special invitation from the President, Dr Joseph C Hutchinson, of Brooklyn, Dr Newman stated that electrolysis acted in different ways according to the manner in which it was used Weak currents would cause absorption, while strong ones would destroy His own experience had been different from that of Dr Craft as regards the comparative painfulness of the action by the two poles Contrary to him, he had found that the positive pole caused more pain, acting, as it did, as an acid caustic, while the negative acted as an alkaline caustic He agreed with Dr Craft, however, as to the propriety of using the positive pole in hernia, when the object was to set up adhesive inflammation The negative pole undoubtedly did cause absorption, and this was the one to be employed in urethral and other strictures

Dr Govan, of Rockland Co , read the report of a remarkable case of fracture of the skull, with depression, from a railway injury, in which the depressed bone became raised spontaneously after the patient had remained in an unconscious condition for several days He also reported a case of poisoning by aniline oil The patient was engaged in removing a carboy of this oil which was accidentally broken, and the fluid completely saturated his clothing He remained in a comatose condition for several hours, and an irritating feature of the case was that from the first there was complete anæsthesia of the entire cutaneous surface On the third day after the accident there was hæmorrhage from the bladder, and this continued for forty-eight hours

In the discussion which followed the reading of this history, Dr E H Squibb, of Brooklyn, remarked that the hæmorrhage from the bladder seemed to indicate that the aniline oil was largely contaminated with carbolic acid or other bi products of the coal tar series It would be interesting, he thought, to note whether the peculiar effects produced in Dr Govan's case would result from poisoning by a specimen of perfectly pure aniline oil The President called attention to the remarkable relief afforded by solutions of carbolic acid in burns, an application which Dr Squibb had suggested to the profession a number of years ago, and Dr Govan said that since he had met with this case he had resorted to the use of aniline oil as a local anæsthetic with very gratifying success In the case of felons, it was possible to cut down to the bone without the patient experiencing any pain whatever, if the finger had previously been immersed in the oil for a short time

Dr Austin Flint read a paper of great interest on the subject of "*Suggestions in Regard to the Causation and Treatment of Acute Coryza*," which is to be published in the JOURNAL Dr Pancoast having asked in what way the active antiphlogistic treatment often used in colds, such as the production of free diaphoresis, etc , was efficient if the parasitic doctrine of the etiology of coryza were true, and whether this efficiency could be made to tally with the latter, the author of the paper replied that he did not see any inconsistency in the matter A full dose of opium, which was always part of the antiphlogistic treatment, was very beneficial in breaking up a cold, just as it was very beneficial in the incipient stages of cholera, where the parasitic origin of the disease could now be regarded as practically established Whether the opium was directly destructive to the parasite or not, he could not say

Dr Wm McCollom, of Brooklyn, read the report of a unique case of uniformly developed cirrhosis in both lungs The principal symptom of this very obscure case during life was progressive dyspnœa, and the only abnormal physical sign which the examination of the chest revealed was the existence of subcrepitant râles on both sides These were attributed by Dr J R Leaming, of New York, who saw the patient several times in consultation, to the presence of extensive pleuritic adhesions, both old and new At the autopsy, the following condition of affairs was found The kidneys were entirely normal, and the liver, with the exception of being possibly a little fatty, was also free from disease The pericardium contained two ounces of fluid, and the right ventricle was slightly dilated Otherwise the heart was perfectly healthy The thoracic aorta was also normal The lungs were of a dark gray or brown color, and floated in water The parenchymatous structure of both lungs was very hard and dense, and creaked under the knife There was no evidence of acute pneumonia, and no cavities were found The only adhesions discovered were two slight ones at the apex of the right lung, and they were evidently of very long standing

Prof Flint stated that he had personally seen the case once, and that he remembered it perfectly He had not been aware before that the patient was dead, but he was very glad to know the result of the autopsy When he made the examination of the chest in consultation with Dr McCollom he could discover nothing but the presence of a moist râle on both sides He then felt sure that the patient had disease of the kidneys, and requested specimens of the urine When, however, the examination of the latter gave a negative result, he felt at a loss in regard to the case, and asked that he might be permitted to see the patient again The condition of the lungs found after death completely explained the progressive dyspnœa, and at the same time it served to illustrate the inadequacy of physical signs under certain circumstances The remarkable point about this case was the equal development of the cirrhosis in both lungs Almost invariably the condition was much more marked in one lung than the other, so that the difference between the two sides of the chest was very apparent. The existence of moist râles in connection with a normal condition of the heart seemed to him to positively indicate kidney disease, and he was therefore surprised to find that the urine gave no evidence of this. On the whole, therefore, he considered it a very interesting case, and the specimens that had been presented by Dr. McCollom he believed were unique. He thought it also worth while, in this connection, to call attention to the mechanism of subcrepitant râles. One observer, as the history showed, had referred these rales in the present case to the existence of pleuritic adhesions. From the result of the autopsy, however, it was pretty evident that the subcrepitant râles were produced in the smaller bronchial tubes, and not in the pleuræ.

At the request of the President, Dr. Pancoast addressed the Association, taking for his subject, "*Some Points in Surgical Practice and Surgical Anatomy.*" He spoke first of what he called the "antiphlogistic touch of the therapeutic knife." If he saw a patient early enough, he said, this enabled him to say with almost absolute certainty that there would be no abscess. He exhibited the little knives which he had devised, which puncture, but do not cut, and which leave no scar, he said that with one of them he punctured the part in numerous places, and let the dead blood out. The method was applicable to tumors of almost any kind, as it afforded the best possible means for deep-seated blood letting of the part. The moment a bubo, or other gathering, became hard and refused to yield to the action of local applications, he freely punctured it with this antiphlogistic knife, and occasionally he said he found that there would be a drop of pus on the point. By this method he had even cured some cases of goitre, both cystic and fibroid, or at least rendered the growth so small that it gave no further trouble. He also gave internal remedies, however, such as Donovan's solution and iodide of potassium, with the addition of cinchona or whisky, if the patient's condition required it.

The next point was one in connection with the surgical anatomy of the face, viz. the special value of the malar bone, which was often overlooked by surgeons. It was one of the hardest bones of the whole skull, and it therefore served as a great protection, while if it could be saved, much deformity of the face could be prevented. In excision of the superior maxilla, consequently, he always made it a point to leave this bone in position, and he then proceeded to describe the operation which he had devised for this purpose. This consisted in a double curved incision, and, after turning back the soft parts, inserting a chain saw through the spheno maxillary fissure, and so cutting through the articulation of the superior maxillary with the malar bone. In this connection he related the case of a lady with a rapidly-growing carcinoma of the face, upon whom he performed this operation, notwithstanding the fact that she was five months pregnant. In two days she had recovered from it, and she afterwards went on to full term without any further trouble.

The value of the malar bone in protecting the brain from injury was well illustrated in the case of a boy, from whose face he extracted the breech-pin of a gun which had been imbedded in it without any one's knowledge for eleven months. The gun had exploded in the lad's hands, knocking him senseless, and the breech pin had buried itself so completely in the tissues that its presence was never suspected by the physician who attended him. This case taught us that under such circumstances we should always examine carefully for powder in the skin, and also make sure some part of the gun has not been imbedded in the face. Although this would seem like a very extraordinary case, it was not unique, similar ones having been reported by the late Dr. J. R. Barton, of Philadelphia, and by a surgeon to one of our ophthalmic hospitals.

Dr. Pancoast next gave some account of his treatment of varicocele, which he said he had seen successfully practiced in more than four hundred cases. It is very simple, and therefore in marked contrast to that so much in vogue in New York, which involved a cutting away of a portion of the scrotum. He did not think the latter a philosophical procedure, because it merely shortened the bag in which the enlarged veins are contained, and this could be more efficiently done by suspending them in a muslin bag, because the latter was indistensible, while the shortened scrotum, consisting of elastic tissues, would gradually stretch more and more, so that the trouble would eventually return. This procedure did not, therefore, go to the root of the evil. Still more complicated and serious was the operation described by Mr. Lee in the *Lancet*, of April 18, 1885, in which he cut open the scrotum and lifted out the veins of the spermatic cord. In both of these operations there was no little danger of erysipelas setting in. In his own operation the patient was cured in three or four days, instead of as many weeks. It consisted of transfixing the scrotum with a sailmaker's needle (which had a good point, but no sharp edges), and passing between the vas deferens and the veins a strong silk ligature, which, having been carried around the latter, was then brought out at the point of insertion. The ends of the ligature were finally secured tightly over a button of German silver or zinc, and the veins being thus strangulated, the ulcerative process went on rapidly.

The other subjects touched upon by Dr. Pancoast were the treatment of the urethral stricture by his urethratome, modeled upon Mr. Symes' instrument, with the cutting followed up by a regular and prolonged course of dilatation, in connection with which he exhibited a metallic catheter bougie, devised by himself, which had an olive shaped extremity for the purpose of preventing puckering of the mucous membrane, the advantages of black silk sutures, which were the strongest made, and, being dyed with iron, possessed marked antiseptic properties, the treatment of ununited fractures of the fore arm and leg, and of fractures of the neck of the femur in the aged, the treatment of incurvation of the penis by an operation devised by his father in which a V-shaped piece was cut from the cavernous bodies a short distance behind the glans, and the utility of entirely extirpating chancres with the knife. He also exhibited specimens showing the results of exsections of the shoulder and hip-joints, with the development of remarkable reparative processes.

It was decided that the next special meeting for scientific purposes of the Fifth District Branch should be held at Yonkers, on the second Tuesday of March, 1886. The prospects for the second annual meeting of the parent Association, to be held in this city in November, are unusually brilliant, and with four days for the purpose, upon three of which there will be three sessions each, there can be little doubt that much good work will be accomplished. P. B. P.

INTERNATIONAL MEDICAL CONGRESS

To the Editor of the Journal:

Dear Sir:—Dr. R. A. Kinloch, of Charleston, S. C., occupies nearly three pages of the *Medical News* in an effort to prove that he alone was right and that all the other members of the Committee of Arrangements, who were present in New York on September 3d, were utterly wrong. Dr. Kinloch frankly acknowledges that he did not approve of the action of the American Medical Association in creating the enlarged Committee, and states that he only accepted a position on the Committee because he "recognized the obligation to serve the Association and indulged the hope of sustaining a spirit of harmony." This quotation looks well in print but its beauty is marred by the fact that the conduct of its author was not in accord with its spirit. If his course of action as a member of the Committee implied any obligation on his part, it apparently implied an obligation to serve a coterie of personal friends regardless of the rights or wishes of the American Medical Association, and so far from endeavoring to sustain a spirit of harmony, he persistently endeavored to obstruct the proceedings of the Committee by frittering away valuable time with trivial objections. The members of the Committee, however, understood the peculiar position in which Dr. Kinloch had been placed, and listened to him with attention, and then voted and acted for the best interests of the American medical profession.

Dr. Kinloch complains that a letter which he forwarded to the temporary Secretary was not read before the meeting of the Committee in Chicago, or embodied in the report which was recently published. I had received nearly two hundred letters at that time, some of which were similar in tenor to Dr. Kinloch's, but the great majority expressed approval of the action of the Association. To have read them all would have occupied the whole day. The Committee therefore directed me to read the one which had been received from Dr. Austin Flint, Sr., the eminent President of the Congress.

Dr. Kinloch's chief grievance, however, appears to be that the Committee exercised its right of filling a number of the vacancies which had been made in several of the important offices of the Congress by the resignation of a number of those who had been previously appointed. According to Dr. Kinloch, many of those resignations were merely tentative in character, and not intended to be *bona fide*, and the appointment of new men to the important places was a manifestation of vindictiveness on the part of the Committee which Dr. Kinloch could not condone. To use Dr. Kinloch's own words: "The work of filling the so called vacancies in the most important offices had continued without any question as to the acceptance of resignations. The spirit of vindictiveness (I regret to have to use the term) under the presumed offence given by the parties who had proposed to withdraw, seemed to me to be irrepressible; so I could not consent to occupy the position which had been assigned me."

I was informed several months ago that many of the published resignations had been forwarded in a half hearted manner, and that many more had been procured by earnest personal solicitation, but that none of the distinguished resigners intended to personally refrain from participation in the International Medical Congress. Their aim was to compel the Association to reinstate the Original Committee with full power to reinstate themselves and their New Code friends in office, to give four positions to one, five to another, six to another, and so on to the end of the chapter. I was inclined to doubt the correctness of this at first, but Dr. Kinloch has corroborated it by practically admitting that many of the resignations were intended only for dramatic effect. Dr. Kinloch and his friends understand by this time, however, that the Committee of Arrangements appointed by the American Medical Association could neither be cajoled nor intimidated. That Committee was created for a special purpose—to provide a preliminary organization for the Congress. Its work has been performed without fear and without malice. The general officers of the Congress and the officers of the various Sections have been appointed and have organized an Executive Committee, who will now take charge of all minor details. Some further vacancies may occur by death or otherwise, but they will be filled by competent and thoroughly representative men who are in accord with the medical profession of the whole country.

John V. Shoemaker, M.D.

Philadelphia, Oct. 20, 1885.

THE AXIS-TRACTION FORCEPS

To the Editor of the Journal:

Dear Sir:—I must confess some surprise in reading the criticism appended to my "Correction" published in Oct. 17th No. of this journal. In the first place, if any one is disingenuous it is certainly the writer of this criticism, who persists in saying, that I did not give credit to Dr. Felsenreich, in spite of the fact, that I have distinctly published and publicly stated, the disputed forceps to be the Alexander Simpson's, with Tarnier's axis traction rods attached by Dr. Felsenreich's buttonhole joint! In the second place, the writer stated that the disputed forceps "is merely a modification of Felsenreich adaptation of Alexander Simpson's axis-traction forceps," and then in reference to Dr. Felsenreich's instrument contradicts himself by saying: "*The forceps to which the* axis traction rods were attached, was the *Wiener Schulzange*, the original model of the Sir James Y Simpson instrument "

Hence, for the benefit of the writer, I will merely reiterate what I have already so often declared and published, that I have now adopted the Alexander Simpson blades

Finally, *I* have entered into communication with Dr Felsenreich on the subject," and moreover, am happy to state, that in addition to this, I have sent him copies of *all* the published articles, with the urgent request that he inform me at once of his opinion, which I shall be pleased to publish if necessary

Respectfully, L E NEALE M D
Baltimore, Oct 20th, 1885

NECROLOGY

SAMUEL GLASGOW ARMOR, M D , LL D

Dr Samuel G Armor died at his home in Brooklyn, on October 27, in the sixty-eighth year of his age He was born in Washington Co , Pa , of Scotch-Irish parentage, on January 29, 1818, and his parents removed to Ohio soon afterwards He received his academic education at Franklin College, Ohio, and in 1872 this institution conferred upon him the degree of LL D

He studied medicine with Dr James T Irvine, of Millarsburg, O , and graduated from the Missouri Medical College, of St Louis, in 1844 Soon after graduating in medicine he settled in Rockford, Ill , and in 1847 received an invitation to deliver a special course of lectures on physiology in Rush Medical college, of Chicago In the following year he was called to the Chair of Physiology and Pathology in Rush Medical College, but declined it because he had just accepted the same position in the Medical Department of the University of Iowa, at Keokuk Subsequently, however, he resigned this position to take the Chair of Natural Science in the University of Cleveland In July, 1853, he was awarded a prize by the Ohio State Medical Society for his essay on the "Zymotic Theory of the Essential Fevers " During the same year he accepted the Chair of Physiology and Pathology in the Medical College of Ohio, having resigned his position in the University of Cleveland

In 1834 he was transferred to the Chair of Pathology and Practice of Medicine About two years afterwards he resigned this position, and removed to Dayton, O , though having accepted the Chair of Pathology and Practice of Medicine in the Medical College of Missouri, of which he was an alumnus In 1861 he removed to Detroit, having accepted the Chair of the Institutes of Medicine and Materia Medica in the University of Michigan Here he remained until 1866 when he removed to Brooklyn, having accepted the Chair of Therapeutics, Materia Medica, and General Pathology in the Long Island College Hospital In 1867, Dr Austin Flint having resigned the Chair of Practice of Medicine and Clinical Medicine, Dr Armor was transferred to this position, which he retained until his death

ASSOCIATION ITEMS

INFORMATION OF IMPORTANCE TO ALL MEMBERS OF THE AMERICAN MEDICAL ASSOCIATION

MEMBERSHIP —Every one who attends an annual meeting of the Association as a delegate pays at that time five dollars, and thenceforward becomes a Permanent Member He continues as such as long as he remains in good standing in the body from which he was originally sent as a delegate As a Permanent Member, he must pay *Five Dollars Annually*, when notified by the Treasurer, whether he attends the meetings of the Association or not Payment of annual dues entitles him to receive the weekly JOURNAL of the Association for one year

MEMBERS BY APPLICATION are such as have not become Permanent Members in the manner above indicated, but apply to the Treasurer for membership, forwarding at the same time to him five dollars and the certificate of the President and Secretary of their State or local society, that they are in good standing in such society They pay five dollars annually thereafter, when notified by the Treasurer Members by application can join the Association at any time, and they receive regularly the weekly JOURNAL

WHEN DUES ARE PAYABLE —The annual dues from Permanent Members are payable to the Treasurer at the time of the annual meeting of the Association, or immediately thereafter The payment entitles the member to receive the JOURNAL for one year from the following July Payment for 1885, for example, entitles the member to the JOURNAL from July, 1885, to June, 1886, inclusive

As some of the members have not yet forwarded to the Treasurer their dues for 1885, they are urgently requested to do so at an early day Having entered upon another year of membership, they are morally and legally responsible to the Association for the payment of their annual dues, having already received for three months of the new year—1885—the JOURNAL of the Association

SUBSCRIPTIONS TO THE JOURNAL, from those who are not members of the Association, should be forwarded to the office of publication, 65 Randolph Street, Chicago, and not to the Treasurer, but *all payments of annual dues must be forwarded to the Treasurer, Lock Box 1274, Philadelphia*

DEATHS —When a member of the Association, who is in regular receipt of the JOURNAL, dies, his family or other representatives are requested to inform the Treasurer at once of the fact

PAYMENT OF DUES FOR PREVIOUS YEARS —As a few members of the Association are still in arrears for payment of dues for 1883 and 1884, they are requested to forward at once to the Treasurer the amounts for which they are indebted to the Association

TRANSACTIONS OF THE ASSOCIATION —These annual volumes, thirty three in number, to 1882 inclusive, may still be obtained, with few exceptions, from the Treasurer, at reduced prices The Index to these volumes will be forwarded on receipt of *One Dollar* An opportunity is thus afforded to complete sets of these valuable publications, or to obtain important papers and works which are daily becoming scarce

Richard J Dunglison, M D, *Treasurer*
Lock Box 1274, Philadelphia, Pa

NINTH INTERNATIONAL MEDICAL CONGRESS, WASHINGTON, D C, 1887

[The following are some of the more important Rules adopted relating to the preliminary organization of the Congress —Ed]

1 The Congress shall consist of members of the regular profession of medicine, who shall have inscribed their names on the register and shall have taken out their tickets of admission, and of such other scientific men as the Executive Committee of the Congress may see fit to admit

2 The dues for members of the Congress shall be ten dollars each for members residing in the United States

There shall be no dues for members residing in foreign countries

Each member of the Congress shall be entitled to receive a copy of the "Transactions" for 1887

3 The Congress shall be divided as follows, into seventeen Sections

I General Medicine
II General Surgery
III Military and Naval Surgery
IV Obstetrics
V Gynæcology
VI Therapeutics and Materia Medica
VII Anatomy
VIII Physiology
IX Pathology
X Diseases of Children
XI Ophthalmology
XII Otology and Laryngology
XIII Dermatology and Syphilis
XIV Public and International Hygiene
XV Collective Investigation, Nomenclature, Vital Statistics, and Climatology
XVI Psychological Medicine and Diseases of the Nervous System
XVII Dental and Oral Surgery

4 The General Meetings of the Congress shall be for the transaction of business and for addresses and communications of general scientific interest

* * * * * * * *

8 The official languages of the Congress shall be English, French, and German

In the meetings of the Sections, no member shall be allowed to speak for more than ten minutes, with the exceptions of the readers of papers and those who introduce subjects for discussion, who may each occupy twenty minutes

9 The rules and programmes shall be published in English, French, and German

Each paper and address shall be printed in the "Transactions" in the language in which it was presented, and preliminary abstracts of papers and addresses also shall be printed, each in the language in which it is to be delivered

All discussions shall be printed in English

10 The President of the Congress, the Secretary-General, the Treasurer, the Chairman of the Finance Committee, and the Presidents of the Sections, shall together constitute an Executive Committee of the Congress, which Committee shall direct the business of the Congress, shall authorize all expenditures for the immediate purposes of the Congress, shall supervise and audit the accounts of the Treasurer, and shall fill all vacancies in the offices of the Congress and of the Sections This Committee shall have power to add to its membership, but the total number of members shall not exceed thirty A number equal to one third of the members of the Committee shall constitute a quorum for the transaction of business

11 The Officers of the Congress shall be a President, Vice-Presidents, a Secretary-General, four Associate Secretaries, one of whom shall be the French Secretary, and one of whom shall be the German Secretary, a Treasurer, and the Chairman of the Finance Committee

12 The officers of each Section shall be a President, Vice-Presidents, Secretaries, and a Council

13 The officers of the Congress and the officers of the Sections shall be nominated to the Congress at the opening of its first session

---

MISCELLANEOUS

Washington Obstetrical and Gynecological Society —At the annual meeting of this Society, held on October 16, 1885, the following officers were elected for the ensuing year *President*, A F A King, M D, *Vice-Presidents*, W W Johnston, M D, J Taber Johnson, M D,, *Recording Secretary*, C H A Kleinschmidt, M D, *Corresponding Secretary*, S S Adams, M D, *Treasurer*, G B Harrison, M D

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT U S ARMY FROM OCTOBER 17 1885, TO OCTOBER 23 1885

Col T A McParlin, Surgeon, directed to wait further orders in New York City (Letter from A G O, Oct 19, 1885)

Lieut Col E P Vollum, Surgeon, assigned to duty as attending surgeon headquarters Dept Platte, Omaha Neb, relieving Asst Surgeon Wm C Shannon (S O 103, Dept Platte, Oct 15, 1885)

Major Anthony Heger, Surgeon, directed, in addition to his present duties as member of Army Medical Examining Board, now in session in New York City, to perform the duties of attending surgeon in that city (S O 240, A G O, Oct 19, 1885)

Major Joseph C Bailey, Surgeon, granted leave of absence for twenty days (S O 225, Dept East, Oct 19, 1885

OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF MEDICAL OFFICERS OF THE U S MARINE HOSPITAL SERVICE FOR THE TWO WEEKS ENDED OCTOBER 24 1885

Long, W H, Surgeon, to proceed to Detroit, Mich, and assume charge of the Service Oct 23, 1885

Austin, H W W, Surgeon, to proceed to Albany, N Y, on special duty Oct 14, 1885

Williams, L L, Asst Surgeon, relieved from duty at Norfolk, Va, to proceed to Washington, D C, for temporary duty Oct 20, 1885

A CLINICAL LECTURE ON LUMBAR ABSCESS[1]

BY EDMUND ANDREWS, M D , LL D ,

PROFESSOR OF CLINICAL SURGERY IN THE CHICAGO MEDICAL COLLEGE AND SENIOR SURGEON TO THE MERCY HOSPITAL

MERCY HOSPITAL CLINIC

SERVICE OF PROF EDMUND ANDREWS, M D , LL D ,
AND E WYLLYS ANDREWS, A M , M D

GENTLEMEN —This patient has a large interior abscess pointing in the right lumbar region There is no deformity to suggest caries of the spine, but the caries might exist without the deformity being yet developed The elder Gross put on record the statement that these abscesses always or nearly always spring from carious vertebræ, and with like uniformity terminate in death Erichsen and others are of the opinion that the causes are generally tubercle

Both these opinions are erroneous The connective tissue in the interior lumbar region is liable to inflammation and suppuration from various causes, just like connective tissue anywhere, and when it occurs, a lumbar abscess results, whether the bone is diseased or not Dr Gross based his opinion on post mortem statistics Now we should reflect that all important as dead-house studies are, yet the pathologist sees there only fatal cases, which differ in many respects from the thousands that recover, and do not appear before him Some dead-house pathologists do not bear this in mind, and judge the living cases too much by the post mortem conditions Certainly many cases of lumbar abscess recover under modern antiseptic treatment, and show no signs, either before or after, of tuberculosis However, do not look at this matter entirely from one side There is no doubt that in many cases caries does exist, and that part of these are tuberculous We live in a somewhat non tuberculous region as compared with the North Atlantic seaboard, tuberculous diseases here being, perhaps, thirty or forty per cent less frequent than there Hence I have no doubt that lumbar abscesses are less frequently tuberculous with us than with our Atlantic coast pathologists

However this may be, the patient before us is not proved to have either caries or tubercle There is no proof of any syphilitic diathesis, and the urine contains no albumen There is nothing to forbid the hope of entire recovery so far as external examination goes

The patient has been already subjected to four aspirations The object of this was two fold *First*, a considerable number of lumbar abscesses can be *completely cured* by from three to eight applications of the aspirator, and *secondly*, if these fail, we at least keep the sac collapsed for a considerable time, and thus enable it to contract its walls and diminish its magnitude When the aspirator method is successful in effecting a cure, you will observe that the pus grows more watery at each drawing, and finally may be almost pure serum In this case, as you remember, we have aspirated four times, washing out the cavity with carbolated water at the strength of two and one half per cent , without effecting any improvement in the pus I conclude that the aspirator plan will not be likely to succeed in this case, and we must proceed to treat it by the open method

Before the development of antiseptic surgery the opening of lumbar abscesses was greatly dreaded Abundant and melancholy experience had shown that immediately after the opening the pus of the vast interior cavern underwent putrefaction, and by its absorption rapidly poisoned the patient Hectic set in, exhaustion followed, and death early or late closed the case I recollect well a gentleman who kept at his office work in fair health until the abscess was as thin as paper, and about to break spontaneously In accordance with the doctrine then prevalent, I had postponed the opening to the latest possible moment Seeing the rupture was about to take place, I took him from his office still in apparent good health, gave him tonics, and opened the cavity A vast collection of pus rushed out, hectic soon followed, and in two weeks he was dead of blood poisoning Now, with antiseptic measures, all this terror has vanished like an ugly dream The internal caries, or tuberculosis, if present, may not be always curable, but the opening of the abscess is no longer a serious danger Let me impress it upon you that so far as lumbar abscess alone is concerned, it is only dangerous when it is so complicated in its internal burrowings that it mechanically prevents you from disinfecting and draining all parts of it We need here a bolder surgery than we have formerly practised to enable us to open up and tube the interior

You see this fluctuating tumor on the patient's right lumbar region, between the ribs and the crest of the ilium. It gives a succussion upon coughing like a hernia, but hernia rarely exists here, and besides, there is no resonance of air in it such as a hernia is likely to present. Still, at the beginning of these cases always test the contents with a small aspirator tube to make sure of the diagnosis. This fluctuating prominence is the outer sac, just under the integuments. A lumbar abscess pointing externally consists of an inner and an outer sac, connected by an isthmus or tube which is sometimes an inch in diameter and sometimes smaller than a pencil. As this outer sac is proved to contain only pus, it may be freely opened without fear, but this alone will not enable you to disinfect the interior sac. Injections thrown into it, even with some force, do not pass freely through the isthmus into the interior cavity. Opening the sac, therefore, widely, I search with my finger for the channel leading to the interior cavern. Usually it will be found just outside the common mass of the erector spinal muscles, where the thin fascia of the abdominal muscles emerges from under its border. Often the inner orifice will be found in the angle formed by the crest of the ilium with the spine. In this case, I find the channel just outside the erector spinæ, and on account of its size readily insert my finger into the inner cavity. I perceive that the latter is ovoid in form—about six inches long, and three inches in its shorter diameter. It is simple in shape, and presents no long passages extending out beyond the reach of my finger. The upper and posterior part extends a little up into a sort of pocket behind the right lobe of the liver, but the end of the pocket is a rounded cul de sac easily reached by the finger, and presenting no extension beyond.

---

[1] Delivered at the Mercy Hospital Chicago

The place where the kidney should lie is vacant. This does not mean that the kidney is destroyed, but only that the abscess, burrowing behind it, has loosened its posterior attachments, lifted it out of the hollow of the ribs, and crowded it with other tissues forward and inward. All along the inner border of the cavity my finger explores the side and part of the front of the spinal column. Here is the place to search for caries. After carefully exploring every part, I find that the bone is everywhere covered with a sound periosteum, which is not thickened as in bony inflammation, and reveals delicately to the finger the natural curves and hollows of healthy vertebræ. I find no naked bone anywhere, and no change of form. These vertebræ are therefore sound. This exploration is important, both for diagnosis, and because in some instances a sequestrum can be found and removed, and in others carious spots can be safely scraped. An examination of the inner surfaces of the ribs shows these bones also to be sound.

This, then, is purely an abscess of the soft parts, and quite hopeful of cure. I now wash it out clean with an antiseptic solution, put in a drainage tube reaching well into the depths of the inner cavity, and dress it antiseptically. You will find that this patient will have no hectic, she will have a good appetite, she will improve in color and flesh, and if the drainage and antiseptic washing be faithfully carried out, she will probably recover.

THE TREATMENT OF PULMONARY DISEASE BY PNEUMATIC DIFFERENTIATION.

BY ALFRED S. HOUGHTON, M.D.,

OF CHICAGO.

A novelty in therapeutics, be it a drug or a device, is liable to suffer one of two fates, *i. e.*, disuse from merited distrust, or misuse from misplaced confidence and unwarranted enthusiasm. If the pneumatic cabinet, which is open to the reproach of novelty, justifies its existence by a promise of sound usefulness, it is to be hoped that the profession will save it from both of these fates. Its proper place and uses should be fully determined by competent and reliable men, and it should be prevented from falling into the hands of unscientific investigators. That it has a useful place among the weapons that comprise a physician's armament, it is the object of this paper to show, but just how extensive its field is, remains for time and thorough investigation to demonstrate.

Dr. Vincent Y. Bowditch, in the *Boston Medical and Surgical Journal* of July 16, and the JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, of August 1, confirms the cases reported by Dr. H. F. Williams in the *Medical Record* of January 17. Dr. Williams' further report of these cases and others before the Climatological Society appears in the *New York Medical Journal*, of October 3.

The cabinet is an instrument by means of which the following results are sought:

1st. The strengthening and developing of weak and poorly expanded lungs.

2d. The arrest of pulmonary disease in its earlier stages.

3d. The prolongation of life with comparative comfort in those cases of pulmonary disease in its later stages where a cure is impossible.

It is well determined that high altitudes have a marked influence over pulmonary disease. It has always seemed to me that John Hughes Bennett was right in saying "that if the process employed by nature could be discovered, and then imitated by art, we might ultimately arrive at the true principle of cure." Acting upon the belief that it was the influence of atmospheric pressure that gave to "high altitudes" their beneficial effects, the cabinet was constructed.

The cabinet is an air-tight chamber, in which the patient sits or reclines, breathing from the outside through a flexible tube. We exhaust a small portion of the air about him, causing a deep, easy and pleasant inhalation, filling every part of the lungs with the air or spray, producing a stronger and more regular circulation, bringing the blood into complete relation with the oxygen of the air, and introducing the medication in every recess with ease; we have now simply aided the patient to take a deeper breath than he otherwise could. We can then either produce a compression of the air about the body, compelling an evacuation of the lungs, and repeat the former movement, or we can continue the rarefied condition and let the patient expel the air by his own efforts In this latter way we produce the same effect upon the lungs that a dumb bell does upon the muscles of the arm, for the effort is to *exhale* and not to inhale We thus have such complete control over the movements of respiration, that we can increase or diminish the force, frequency and depth of each breath at our pleasure, and without the slightest effort or discomfort on the part of the patient

In addition, the mucus which patients attempt to remove by coughing, and which they can often only detach in small portions and sometimes not at all, is by this method loosened and easily expectorated The lungs can also be medicated and disinfected in a better manner than by any other method The Semple Inhaler is the best spray-producing apparatus I have ever seen

The following are the solutions that I have found useful, the last four being prepared expressly for Semple's Atomizing Inhaler by Parke, Davis & Co The vehicle consists of fluid cosmoline, and in combination with various oils and balsams, the spray being more like a smoke

These last should always be diluted with cosmoline So far as the medication is concerned, we have in the cabinet a means by which agents can be more easily, thoroughly, and deeply introduced than by other means, as is evident from the following facts

Volumetric tests have shown us that by the use of the cabinet the amount of air inspired during each inspiration is increased from 50 to 100 per cent over the amount inspired during normal tranquil respiration This air is saturated with the medicament, as already explained Repeated and exact hygrometric and manometric tests have shown that if air is thus (unconsciously to the patient) introduced at a pressure of five-tenths of an inch, the effort to expel the same, or the expiratory movement, as well as the friction and inertia of the air passages, is equal to five inches, or an increase of 950 per cent, or a corresponding diminution of moisture in the air inhaled, against this, however, we have to consider the increase in moisture carrying capacity due to higher temperature in the lungs, taking this into consideration, we have between the inspiratory and expiratory movements a reduction in vapor carrying capacity and a consequent condensation of vapor at the farthest point reached by the inspired air, and as our volumetric measurement has shown that the entire air capacity of the lungs is occupied, the entire aerating surface must be bathed with the condensate, numerous experiments have shown this to amount to about twelve per cent of the medicament used Thus it will be seen that the effect of differentiation alone is not by any means the only beneficial action of the cabinet

In contemplating the differential process more especially with reference to the respiratory movements and their effect upon the pulmonary capillary circulation, I have been so impressed with the intimate connection between them that I have come to conclusions that, while they are apparently at variance with much that has the sanction of investigation, nevertheless seem to me to harmonize with and rationalize much that is not very clear Instead of regarding the initial steps in the tuberculous process as due to external and specific causes, I have come to regard primary pulmonary infiltration, whether it be perivesicular or intervesicular, as the result of a simple mechanical law, *i e, that force operating behind and resistance offering in front results in an unvarying manner, dependent upon the amount of force and the extent of resistance* The force in this case is the right ventricle, the resistance resides in the pulmonary capillaries

But here comes into consideration another force which we shall find is to exert no small influence, viz the movements of respiration, for they may act to either increase the force operating behind or the resistance offering in front, the result being very different in one case from what it is in the other Atmospheric pressure acting upon the pulmonary capillary circulation can effect either its retardation by antagonizing the action of the heart, or its acceleration by overcoming the resistance of the capillaries The right ventricle alone is physically unable to propel the blood through the pulmonary capillaries with sufficient force to bring back a sufficient quantity to the left auricle to maintain the circulation (Draper) When the pneumogastric nerve is cut and the movements of respiration retarded and eventually stopped, we find the lungs solidified in a peculiar manner, for they are smaller and empty of air (Dalton)

What, then, is the force that carries on and perfects the capillary circulation through the lungs? If we produce artificial respiration in an animal in which the movements of respiration have been abolished, and in which the capillary engorgement has occurred, together with arrest of the heart, we will not only overcome the engorgement but reestablish the cardiac pulsations (Dr Cartwright, *Boston Medical Journal*, Jan 7th, 1852) It is therefore *proved* that the movements of respiration are the mechanical aid in complete pulmonary capillary circulation. Now comes into consideration whether inspiration or expiration is the essential force in propelling the blood to the left auricle

[Note —It is held that during inspiration the effect of the diminished atmospheric pressure within the thoracic cavity not only causes the expansion of the lungs and inspiration of air, but also the *aspiration* of blood into the thoracic blood vessels, that this does occur to a certain extent is certainly proved, but not to the extent of affecting the pulmonary capillary circulation, is evident when we consider to what advantage the atmospheric pressure acts through the open trachea and bronchi upon the air vesicles, as contrasted with the closed and resisting tissues about the systemic circulation. Foster, in his work on Physiology, devotes several pages to this subject, but one important fact is overlooked, and that is, that no amount of rarefaction about a vessel will cause its expansion unless its cavity communicates with the atmosphere, for it is the pressure of the atmosphere that compels the expansion. To talk about the aorta being increased in calibre by the effort of inspiration, seems absurd, and, when we come to consult the diagram he gives of the effect on blood pressure and its relation to the intrathoracic pressure produced by the respiratory movements, we find that the opposite from what we had been led to expect, was true. He says: "When, however, the respiratory undulations of the blood pressure curve are compared carefully with variations of intrathoracic pressure, it is seen that neither the rise nor the fall of the former are exactly synchronous with either diminution or increase of the latter." The fact is, that the rise in arterial tension follows closely the inspiratory act, and that the fall corresponds with the expiration. What does this teach? That inspiration is a *force*, that it is the "*prime* force in originating the circulation" (Draper). My experiments with atmospheric pressure during the last two years compel me to this conclusion.

How can atmospheric pressure affect cerebral circulation, protected as it is by the unyielding calvarium? Is it not a much more rational explanation to give to the increased arterial tension due to inspiration, the position of cause in the cerebral wave mentioned by Foster?]

Having decided that inspiration is *the* movement that furthers the capillary circulation through the lungs, we now come to consider the effect of expiration. If we study the microscopical appearances of a pulmonary lobule, we find that the capillaries dip down between the alveoli, and are so arranged that the expansion of the air vesicles *must compress* them, and that the contraction of the air vesicles must not only allow them to be fully filled with blood from the right heart, but compel a temporary stasis of the blood in them, owing to the increased resistance which the absence of inspiration permits. It is shown, then, that inspiration acts to further the pulmonary circulation by removing the stasis that has occurred during expiration, and overcoming the capillary resistance in front, but the moment the movement of inspiration ceases, the stasis re-occurs, for the force that has been acting ceases, the diaphragm begins to rise, the ribs to fall, and the atmospheric pressure is overcome.

What happens then, when the inspiratory movement is not vigorous? By vigorous, I mean normal vigor, sufficient to expand every air-cell, but not forcibly. When any portion, no matter how small, is not fully expanded? There must be stasis, and attendant upon stasis transudation, dependent upon the extent of non-expansion and its area. Now, where will such transudation occur? We have shown that when the movement of inspiration is not exerted in any portion of the lungs, no matter how small, it increases the resistance, and consequently the point of deposit must be on the cardiac side of the resisting point, into the weakest structure, therefore *perivesicular*.

But we have another condition when the movement of inspiration *is* not only vigorous, but forcible, when the heart's action is also vigorous, when force is augmented by force, but now the point of resistance has passed to the thin wall of the fully expanded air cell, and the rupture and deposit takes place there, and we have *intervesicular deposit*. In other words, we have in the first case, a passive condition of the lungs acted upon by a force that alone is unequal to the task of overcoming the resistance, and the stasis that follows results in perivesicular deposit. In the second case, we have an active condition of the lungs acted upon by an accelerated heart, increased primarily by the inspiratory movement, but resisted secondarily by the same movement having been converted from force into resistance, resulting in intervesicular deposit.

[NOTE.—To make this latter point clear, let me remind the reader that in forced inspiration we have, as is seen in emphysema, an exsanguinated condition of the alveolar capillaries, imagine, therefore, a vigorous inspiratory movement not sufficient to cause emphysema, but such as one takes when subjected to sudden cold, at a time when the heart's action is rapid and forcible, as the air cell expands it augments this force, especially, as towards other lobules, in which the expansion being forced, it reaches the point when it becomes resistance. I do not mean that under such circumstances transudation always occurs, but when for any reason it does occur, it must be into the air cell itself.

Let x represent the heart's force, y the inspiratory vigor, and z the capillary circulation. Then we may represent these conditions by the following equations:

$$x + y = z$$
$$x - y < z$$
$$x^2 + y > z$$
$$x < y + z$$

With perfect equilibrium between force and resistance, no deposit can occur. Deposit once having occurred, the subsequent changes depend on varying influences. The bearing of this upon pneumatic differentiation is clear, because, if correct, the rational treatment (theoretically) is to restore the equilibrium between force and resistance, and it naturally follows that the nearer we approach to the condition of primary deposit the more readily can aid be afforded. Let us see then if *theory* is borne out by experience.

It may be here objected that the pressure used in the cabinet must be greater than vigorous inspiration, and therefore further the production of intervesicular deposit I do not doubt that this is possible, if the pressure be carried up to two or three inches, but this is never done, and further coughing exerts more strain on the air cells than is possible in the cabinet, further, it is shown that the heart is not accelerated

Dr Williams reported in the *Medical Record*, of January 17th, sixteen cases of primary deposit and acute phthisis, ten of whom recovered It was my good fortune to be familiar with the majority of these cases, and to examine them, and it is hardly necessary to state that the nearer their condition approached the primary deposit the more complete was the removal of the adventitious sounds

In reporting the following cases, I shall classify those of phthisis more in accordance with their acuteness or chronicity (that is nearness to primary deposit) than with reference to their anatomical or pathological characteristics, accordingly I shall speak of acute phthisis as consisting of three stages the first extending from the initial infiltration to the beginning of the febrile movement, the second extending from the advent of the febrile excitation through the period of deposit extension to the period of septic disintegration, which constitutes the third stage of excavation I shall include under the term chronic phthisis, those cases of chronic pleurisy and chronic pneumonia that have fibroid pulmonary deposit and also syphilitic phthisis I consider the *first stage* of phthisis as present when the slightest evidence of diminished pulmonary expansion and respiratory vigor is present, and it is here that the influence of pneumatic differentiation, together with action of well selected agents, cuts short the impending process I regard the second stage as beginning when the temperature runs above 100° or 101°, it is here that antiseptics and germicidal agents must be pushed to the limit of prudence if we hope to prevent the development of the third and *last* stage, when septic degeneration and excavation have taken place Dr Williams reports five recoveries in patients who had reached this stage Such results seem almost incredible, and are shown by further reference in his last publication to be exceptional, yet these undoubted results inspires the hope that by judicious selection of 'antiseptic," "tonic," or perhaps "nutritive" agents we can at least prolong the lives of such patients in comparative comfort

The following table embraces all the patients that I have independently treated with the Pneumatic Cabinet, ten of whom were treated with a primitive apparatus in Milwaukee These ten embrace three of primary deposit, two of second stage, one of third stage, and one of chronic phthisis, two of whom died

	No of Cases	Recoveries	Improvements	No Improvement	Result Unknown	Deaths
Chronic Bronchitis	5	1	1	1	2	
Asthmatic Bronchitis	2		1	1		
Asthma	1	1				
Acute Phthisis first stage	9	4	4	1		
second stage	4		3	1	1	
third stage	5		1	1		2
Chronic Phthisis	7		2		3	2
Unresolved Pneumonia	1		1			
Total	34	6	13	5	6	4

Number in whom result is not known, six, of whom six took less than three treatments each

Of the four cases of acute phthisis, first stage, that were improved, two are still under treatment, one is in California for the winter, and the other took treatment in Milwaukee up to the time the apparatus was useful, the one case that did not improve only took nine treatments Of the three cases of phthisis in the second stage that improved, two are still under treatment, one went to California a year ago and I have not heard from him since The case of third stage phthisis that is marked as improved, was already almost fully recovered when she came to me through Dr Casselberry, of this city, she took seven treatments, and the doctor thought her slight cough was better, and noted an increase in expansion of half an inch The two cases of chronic phthisis that were improved were both fibroid in character, one has gained ten pounds in weight and half an inch in expansion, the other about half an inch in expansion The deaths in chronic phthisis occurred in advanced cases, one of fibroid phthisis, with bronchiectasis, the other of syphilitic phthisis

One death in the third stage occurred in a case in which the symptoms of septicæmia were the most violent I have ever seen, the other was in a case in which decided and continued improvement was present so long as the apparatus was air-tight The following is the history

Mrs E O, aged 40, married, present weight 130 pounds First seen August 21, 1884, with Dr O W Carlson, Milwaukee History of pneumonia two years previously, followed by great emaciation, night sweats, cough, with profuse expectoration and hæmoptysis Physical examination revealed dulness, increased vocal fremitus and resonance, with bronchophony lower lobe of left lung Temperature, A M, 100, P M, 101 2, pulse 100, respiration 29 First treatment was solution No 2, under pressure of two-tenths of an inch for ten minutes This treatment was continued thrice weekly, the pressure being gradually increased to seven tenths of an inch

November 6th her weight was 139 pounds Temperature had been normal for two months, and respiration 16 The cabinet gave out Oct 29th, and on the 13th of November her temperature was 101 2, after that she gradually grew worse and died last spring

Of the four cases of recover in first stage phthisis all but one had more or less deposit, she complained of soreness of the chest, with cough, and as her brother had died of phthisis, her friends brought her to me for the purpose of strengthening her lungs She is now perfectly well, the moral effect of the treatment has removed the morbid fear she had of consumption The other cases I will give as full an account of as space will permit

Case I —Henry B, aged 15, came to me through Dr P C Jenson, who will give a full account of the case (See following article, this number, p 510)

May 29th Henry weighed 72 pounds, and was quite anæmic Physical examination showed marked infra clavicular depression, increased vocal fremitus and resonance, dulness and diminished respiratory murmur, and cog-wheeled respiration on the right side at apex and infra clavicular region Temperature, A M , 97 8, P M , 100

June 3d, marked improvement, weight 73½ lbs Temperature, A M , 98, P M , 100

June 10th, continued improvement, weight 75½ lbs Temperature, A M , 98 5, P M , 99

June 23d, temperature has been normal for a week

July 8th temperature has been normal since, now weighs 86 lbs

September —Physical examination shows only slight roughness on expiration

Case 2 —Sarah W , aged 25, unmarried First seen during miscarriage Under these circumstances her real name was never learned At this time she had a cough, and I advised her to try the treatment as soon as she was able

May 30th —She came to my office for her cough, she said Upon examination evidence of collapse and slight perivesicular deposit were discovered at both apices *Temperature 99 5, pulse 100*

June 6th —Considerable improvement Temperature 99, pulse 100

June 13th —Great improvement Temperature 98 4, pulse 80

On examination I found a free respiratory murmur at both apices, no roughness nor jerking

July 16th —Is now entirely recovered The treatment in this case was solution No 1

Case 3 —Miss J S , aged 25, single Present weight, 125 pounds First seen with Dr Robert H Babcock, who furnishes the following history "Patient was prostrated last May with what she supposed to be a severe bronchitis The writer (Dr Babcock) was called to see her and after repeated careful examinations of the chest and an observation lasting several weeks, came to the definite conclusion that the case was one of incipient tuberculosis of the apex of the left lung Under appropriate treatment she improved, and in June was able to be about Desirous of trying the effect of pneumatic differentiation in her case, the writer persuaded her to take a course of treatment from Dr Houghton "

Record as kept by Dr Houghton

June 4th, 1885 —First treatment, *no spray* at any time, 3 pressure, 16 respiration

June 20th —Fifth treatment, 3 inches expansion, 9 pressure, 11 respiration

June 29th —Ninth treatment, 8 pressure, 5 respiration

July 3d —Twelfth treatment, 4½ inches expansion, 8 pressure, weight 130 pounds

July 27th —Sixteenth and last treatment, 5 inches expansion, 8 pressure, weight 130 pounds

Sept 17th —She was looking very well, and voice much stronger Weight 136 pounds Went with opera troupe as chorus singer

"These treatments were continued at intervals of several weeks *The one result, established beyond doubt,* was a better expansion of the chest The anterior border of the left lung, which had been previously somewhat retracted and evinced, during percussion, but slight, if any, expansion upon forced inspiration, revealed in August last less retraction, and showed ampler excursion movement during inspiration The writer was never able to satisfy himself that the pitch of the percussion note over the affected apex became any lower, or that the respiration revealed any other change than a disappearance of the jerkiness which had first characterized it in a circumscribed area Whether the disappearance of her cough and expectoration was due to the treatments in the cabinet or to the improvement in her health from other causes, is a question Subsequently, in September, her cough and expectoration returned " [Signed] ROBERT H BABCOCK, M D

Taking all things into consideration, I am impelled to the following conclusions, *i e*, that

1 Pneumatic differentiation is of undoubted service in all conditions of primary infiltration

2 Where the febrile movement has been unchecked for many weeks before treatment, improvement, if any, will show itself within the first ten or twelve applications, if there is no abatement of symptoms *its continuance is of questionable utility,* and *it may* be absolutely contra-indicated

3 That phthisical disease at the apices is more favorably treated than when at the base of the lungs

4 That it is possible by this means to more thoroughly medicate the lungs than by any other known method

5 That the expansion of the lungs by differentiation is itself a therapeutic measure of great merit

6 That peri- and inter vesicular exudation is capable of cure by this method, and even third stage phthisis is benefited, at least temporarily

My experience is that when the febrile movement is excessive, when the evidences of septicæmia are pronounced, it is not wise to use the pneumatic cabinet certainly until these symptoms have subsided In cases of chronic bronchitis I have had so little experience that I can only say that if the proper remedy can be found its application is easy enough *Articles and authorities consulted on the subject of* pulmonary capillary circulation as affected by the respiratory movements were

ACUTE CATARRHAL PHTHITIS, RECOVERY

BY P C JENSEN, M D ,

OF CHICAGO

On April 25, 1885, I was called to see H B , æt 14, who had been sick three weeks with catarrhal pneumonia, for which he had been treated by another physician, and a favorable prognosis had been given

The persistency and continued aggravation of the symptoms changed his diagnosis to phthisis, and he now gave an unfavorable prognosis

When I took charge of H B , I found him greatly emaciated, with large and well marked subclavicular depressions, and but little respiratory mobility He was continually getting more debilitated from loss of appetite and exhausting night sweats There was an almost continuous cough, a profuse purulent expectoration, offensive in character, containing much solid substance which would sink in water In color it ranged from grayish white to greenish brown The temperature reached 102° in the afternoon, but was subnormal in the morning The respiration was short, hurried and superficial, about twenty eight to thirty two per minute Pulse 120 to 140 per minute, volume small, and beat irregular

Physical Examination —On auscultation, bronchial râles were distinctly heard, due to exudate in the bronchial tubes There was audible a hollow or cavernous sound, as if a small cavity existed in the right lung There was decided bronchial respiration of right lung, and an almost complete absence of the normal vesicular respiratory murmur on the same side, while over the left side the lung sound was exaggerated (puerile respiration) The impulse of the heart apex could be distinctly felt on the right side, and was still more distinctly audible by the stethoscope, thus indicating a partial consolidation of lung structure on that side

The medical treatment consisted of the following combination

℞	Tr Nucis Vomicæ	gtt x
	Tr Digitalis	gtt vj
	Maltine	ʒiij
	Syrupi Hypophosph Comp	ʒj
	M	

S Take one half hour before mealtime three times daily

℞	Quiniæ Sulphatis	gr ij
	Pulv Iodoformi	gr ij
	Ferri Sub Carbonatis	gr ij
	Ext Belladonna Alc	gr 1 5
	Podophyllin	gr 1 20

M et ft Capsule No 1
Sig One capsule after each meal

As the patient was in a wasting condition, and as malassimilation and denutrition only increased the exhaustion and debility, remedies whose action promotes nutrition and tonicity were indicated To aid in this direction, one ounce of cod-liver oil was given by inunction three times a day The parts selected for the application of the oil were the axillary spaces, groins, bends at elbow joints and popliteal spaces Preceding the inunction, the parts were rendered hyperæmic by friction with mustard, which facilitates absorption To aid in checking the night sweats, and also for its soothing anodyne effect in relieving the irritability of the lungs produced by movement, a large belladonna plaster was applied over the chest Belladonna plasters act indirectly, but very efficiently, in giving relief to cough and local pain by quieting the irritability upon which the cough depends Improvement began immediately , the night sweats gradually subsided, the appetite increased, and in three days from the commencement of the iodoform treatment the sputa had lost its odor, and the quantity expectorated much diminished The cough was relieved for a while by the remedies given, but was afterwards checked by the following mixture

℞	Morphiæ Sulphatis	gr j
	Ant et Pot Tartratis	gr ij
	Ammonii Carbonatis	ʒss
	Acidi Hydrocyanici Dil	gtt xxi
	Spts Chloroformi	℥iss
	Syr Bals Tolutani q s ft	℥iv
	M	

S Take one half teaspoonful every three hours

In about three weeks from commencement of my treatment, H B was sitting up convalescent, but seemed apparently at a stand-still The respiratory murmur still partook of the bronchial character, and the temperature would not go below 99 5°, except in the morning, when it was always subnormal Thinking that if we could clean out his lungs and free them from the accumulation of pathological exudates, he would soon recover, my attention was directed to the Pneumatic Cabinet Dr Houghton thought the case one which would be benefited by the Cabinet He examined the patient in my presence, but could not then, nor could I detect any cavity at this time But Dr Houghton agreed with me in the diagnosis first stage of acute phthisis, with intervesicular deposit

The spray, which was used by inhalation in the Cabinet, consisted of one part corrosive sublimate and a small quantity of ammonium muriate to 500 parts of water The improvement in the patient from that time on was astonishing The patient states that the metallic taste peculiar to mercuric chloride spray was perceptible all day, and that the taste was distinctly imparted to the sputa This seems to me fair evidence that the spray must have penetrated the minute ramifications of the bronchioles and air vesicles This brings me up to Dr Houghton's notes (see previous article, p 509)

The anæsthetic effect of iodoform, and the peculiar symptoms of perverted sensation, muscular incoordination, diplopia, etc , are due to its action in part upon the nervous system In regard to the internal use of iodoform, I would say that I have used it considerably, both in syphilitic, scrofulous and phthisical cases, but in the last two only when purulent or putrefactive changes are going on In cases where there is much expectoration of an offensive character in various stages of decomposition, good results have been obtained by internal administration of iodoform I believe it has a restraining influence over such pathological changes as ulceration, suppuration, necræmia, necrosis, tuberculosis, and retrograde metamorphosis in general Iodoform, whenever administered internally, should be given with caution, as it is a powerful depressant to the circulatory and respiratory systems In cases in which it has been given in large single doses, and occasionally in persons where small doses have been given for a considerable length of time, bad results have been observed In the "National Dispensatory," 2d edition, page 782, we read as follows "Several cases of poisoning by this preparation have been recorded A woman affected with syphilis had taken in the course of four months about 42 grmm's (℥i ʒiij) of iodoform in pills containing each one centigramme ($\frac{1}{6}$ gr) She was suddenly attacked with faintness, vertigo, and double vision, within two days she sank into a deep sleep which lasted for thirty six hours, and was followed by excitement, violent headache, and confused speech These symptoms were succeeded by debility and a tottering gait, after which the vertigo, headache and diplopia recurred This series of symptoms lasted for a fortnight In the case of another woman, the toxical phenomena occurred at the end of the first week, and when no more than 5 grammes (75 grs) of iodoform had been taken She slept continuously for five days, after which debility and vertigo were experienced for several weeks (Oberlander) "

In my own experience, I have observed no such phenomena from the use of iodoform internally But in every case in which I have employed it as an internal remedy, the combination with nux vomica, digitalis, and ext belladonna overcomes or prevents its depressing influence upon the circulation and respiration, and as these remedies are cardiac and respiratory tonics, I think it a most rational method of obviating the dangerous effects sometimes resulting from the internal use of iodoform

FRACTURE OF THE RIB CAUSED BY SNEEZING

BY HAL C WYMAN, M D

SURGEON TO THE WEST END DISPENSARY DETROIT, MICH

There is a Hebrew legend which says that before the days of Jacob no man sneezed more than once—the effort cost him his life Jacob invoked the blessing of God and survived an attack, and since his time it has been customary for persons, in the presence of one sneezing, to utter a "Praise God!" "Gesundheit!" or other significant exclamation, lest the phenomenon result fatally That sneezing may not, in all cases, be the harmless action it is commonly believed to be, the following case will serve to illustrate

Mr M, aged 72 years, remarkably vigorous and healthy for his years, summoned me hastily for relief of severe pain in his right side, which had commenced suddenly after sneezing with unusual force I found him standing, supported by a chair, his face pale, his breathing difficult and provoking cries, with pain in the lower part of the right side I suspected pleuritis and neuralgia, and was surprised on placing my ear on his chest to hear distinctly the crepitus peculiar to fracture of bone Further examination showed a fracture of the eighth rib, near its angle The treatment consisted in placing three strips, fourteen inches in length, of Seabury & Johnson's rubber adhesive plaster obliquely over the right side, crossing the ribs at right angles The plasters were adjusted with sufficient firmness to draw the ribs snugly together, and to limit the motion of the fractured one Recovery was prompt and without complication

This case is of interest, because it was unquestionably caused by sneezing, and the fact that sneezing is not usually referred to as a cause of fracture of the ribs A glance at the mechanics of sneezing will show that two powerful sets of muscles may be brought into antagonism in a way to expend their opposed forces upon the ribs, making the fracture simply a mechanical matter

The treatment by means of plasters having some permanency of adhesive power has proven in many cases of fractured ribs, as it did in this one, a great advantage over the old method of a broad bandage encircling the chest It permits freedom of motion on the uninjured side of the chest, while it insures sufficient immobilization of the fractured bone to control pain and favor union

It is said that insane persons are particularly prone to fracture of the ribs, and that sneezing among them is not infrequently the cause Whether there is, in these cases, a dominant frailty of rib structure, or an unusual quantity of muscular force called out by the mental unsoundness and applied to the ribs in the act of sneezing, is an interesting point to determine

OPERATION FOR MALFORMED AURICLE[1]

BY S S BISHOP, M D,

SURGEON TO THE ILLINOIS CHARITABLE EYE AND EAR INFIRMARY
AND SOUTH SIDE FREE DISPENSARY

On July 11th, 1885, Nettie H, eight years old, presented herself at my clinic at the Infirmary and said she "wanted her ears put back" Both auricles were so abnormally prominent as to mar materially the symmetry of a very shapely face and head The left auricle, which was the more unsightly, projected one and one fourth inches at a right angle from the junction of the auricle with the mastoid process, and then bent forwards, thus forming what is facetiously termed "lop-ear," or "dog-ear" The natural elevations and depressions were obliterated, and the organ presented the appearance of having been flattened by the pressure of the head in sleep on an auricle folded forward upon itself The right ear projected one inch, but was not as imperfectly shaped as the left one At first I contemplated moulding the auricle into shape in a dressing of plaster of Paris, which would retain the parts in position for several months, with proper care and renewed dressings But on account of the youthfulness of the child, which would render it highly improbable that she would cooperate in that treatment with sufficient persistence to insure success, I performed an operation, with the consent of her parents, and with the assistance of Drs Hawley, Abbott and Walker

On July 17th the little patient was anæsthetized with ether An incision one and three-fourths inches long was made on the posterior surface of the auricle about one-half inch from the free border of the cartilage, and parallel therewith Another curvilinear incision internal to the first was made, to unite its extremities These incisions extended only through the skin and subcutaneous tissue, and were made to embrace about one half inch of integument at the widest divergence of the lines of incision After dissecting off this skin and subcutaneous tissue, two incisions parallel to the first were made through the cartilage, and an elliptical section of this was dissected off from the skin covering the anterior aspect of the auricle, without wounding that integument The portion of cartilage removed was not quite as wide or long as the section of skin taken from the posterior surface of the auricle The edges of the wound were united by three sutures, which included the skin only, and the parts were dressed with absorbent cotton and net bandage

---

[1] Read before the Chicago Society of Ophthalmology and Otology, August 11, 1885

Union by first intention occurred and the sutures were removed the fifth day However, the patient chose a pleasure excursion in preference to the clinics before the wound had healed thoroughly, the dressing became displaced and the wound was torn open along the centre Consequently this portion of the wound healed later by granulation There was but slight pain or swelling, and the child evinced no dread of an operation on the other ear except with respect to the ether

The result of the operation is that the auricle now projects but three-fourths of an inch instead of one and one-fourth inches, making a difference of one-half inch between the projection before and after the operation Besides this, the natural elevations and depressions which are requisite to the beauty of a well formed ear have been restored

I do not know that any surgeon has previously performed an operation identical with the one I have devised, but when a learned professor informs the French Academy of Sciences that before the illustrious Jenner was born, and "from a period so remote that it loses itself in the night of time," the inhabitants of Senegambia have practiced inoculation for the prevention of a contagious disease, I have not the temerity to call any operation new A short time since I thought I had originated another new method of treatment, when to my surprise I learned that Dr Sexton, of New York, had been experimenting in the same direction, although he had not published the fact Drs Ely and Roosa have operated in a different manner to effect a similar result They transfixed the auricle at its junction with the side of the head, and removed the cartilage and the skin covering both the anterior and posterior surfaces

By the operation which I performed it is apparent that the integument covering the anterior surface of the auricle, or the part most exposed to view, was not at all injured I was not able to ascertain the exact results in Dr Ely's case In Dr Roosa's case the projection before the operation was the same as in mine, but the projection in my case after the operation was one eighth of an inch less than in his

---

REMOVAL OF THE ENTIRE TIBIA

BY B F HART, M D ,

OF MARIETTA O

In December, 1883, I was called to see a boy, aged 13 years, who had been treated three weeks for rheumatism On examination, I found the leg much swollen, very hot and painful, with marked fluctuation the result of extensive periostitis The boy was very anæmic, and much exhausted

I opened the leg at its upper third, and anterior aspect, and discharged over a quart of pus and broken down tissue A rubber band was applied, and a restorative course of treatment was given for four weeks, until the system could be restored sufficiently to permit the removal of the diseased bone On January 30th, 1884, with the patient under influence of chloroform, I began an incision close to the knee, and finding no sound bone, continued the same to the ankle, and by the use of the enucleator, separated the tibia from its epiphysis

The upper end having been loosened by disease, the entire bone was easily removed With the raspatory I scraped the tibial side of the epiphysis at the knee After dressing the wound with oakum for ten days, it was gradually drawn together by means of adhesive straps In ten weeks the new bone had so far re formed that he could bear his weight upon the limb About four months elapsed before he was able to walk without the aid of crutches At this date (October, 1885) recovery is perfect, tibia full size, and there is no halting in his walk

---

MEDICAL PROGRESS

ANATOMY AND PHYSIOLOGY

WHAT BECOMES OF THE BILE IN THE ALIMENTARY CANAL —Schiff admitted in 1870 that there was a circulation of the bile from the liver to the intestinal canal, and *vice versa*, as it seemed to him that the quantity of bile was always increased when bile was introduced into the canal Sokoloff denied both the fact and the theory, for after injecting glychocolate of soda into the intestine of a dog, he could find none in the bile

A WEISS has recently repeated these experiments, and the results are published in the *Bulletin de la Societe Imperiale des Naturalistes de Moscou*, 1884. He made injections of glychocolate of soda into the intestinal canal of a dog for three days, killed the animal, and examined the contents of the gall-bladder for the glycocholate of soda His results were contrary to those of Sokoloff The presence of glychocolate of soda was established by the reaction with neutral acetate of lead, and by Hoppe's quantitative method, by which the quantity of cholalic acid and sulphur are determined From the quantity of sulphur the taurine is found, and consequently the taurocholic acid Weiss found a surplus of cholalic acid, which could only have come from the glychocolic acid introduced in the experiment, and which had passed into the bile Had glychocolle been introduced instead of the glychocholate, the result would have been different the bile would have contained taurocholates only If cholalate of soda be introduced, it passes into the bile in small quantities, and glychocolic acid is found, by giving the cholalate only a small quantity is found In the first case it is combined with the glycocoll, in the second glycocholates appear, cholalic acid, which is not found in the natural state, being really combined with taurine and glycocoll in its passage through the liver. Finally, by giving a mixture of taurine and cholalate of soda he found 2 per cent. of glycocholate in the bile, which result supports the preceding theories.

Weiss then reviews Schiff's theory, as to whether fresh and decomposed bile (decomposed in the intestine) circulate continually from the intestine to the liver. The bile is partially decomposed in the intestine, and reconstituted (reorganized) again in the blood and liver, by the union of the taurine and glycocol with cholalic acid. He has found that the introduction of cholalic acid into the stomach increases the quantity of the coloring matters of the bile, while glycholic acid has no such effect.

MATERIA MEDICA AND THERAPEUTICS

HYDRONAPHTHOL, A NEW ANTISEPTIC.—In an article on the antiseptic properties of this new substance, DR. GEORGE R. FOWLER, of New York, gives the following history.

Hydronaphthol belongs to the phenol series, and bears the same relation to naphthyl, the hypothetical compound radical of naphthalin, that carbolic acid does to the compound radical phenyl. Thus, carbolic acid was formerly regarded as the hydrated oxide of phenyl. Hydronaphthol, considered in the same way, would be a hydrated oxide of naphthyl. At the present time, however, these hypothetical compounds, phenyl and naphthyl, are considered as obsolete, and not capable of existing. In fact, carbolic acid is regarded as an oxide of benzol, or as a benzol in which one of the hydrogens is substituted by one hydroxyl (O H). Naphthol is obtained from the sodium naphtholate by decomposing it with hydrochloric or sulphuric acid; it is then purified by distillation.

Hydronaphthol is a derivative of the hydroxyl substitute of naphthalin, which latter of itself possesses antiseptic properties of sufficient value to have already excited notice and a desire to learn more of its compounds. The term "hydronaphthol," though perhaps not, strictly speaking, correct yet conveys sufficiently well its character and relations to naphthalin, and at the same time is a convenient term for every day use. It has been but recently discovered that it possesses antiseptic properties, and the claim is made that it is from ten to fifteen times more efficacious than carbolic acid. It is the most promising antiseptic of the phenol series, and, besides, possesses so many other advantages over substances now used for this purpose that it bids fair to supersede many of these. In surgical practice it will take the place probably, of carbolic acid. Of the many new members of the phenol series which have been discovered since Calvert called attention to carbolic acid about thirty years ago, and which have been utilized in the industrial arts, some are better antiseptics than the latter. With but one or two exceptions, however, none have obtained any prominence as germicidal agents. Carbolic acid, though a fairly reliable antiseptic in strong solutions, when so used, involves some risk to life, from its corrosive action upon animal tissues and well-known poisonous properties. In weak solutions it is exceedingly unreliable, and its disagreeable odor often hides that of putrefaction, instead of preventing the occurrence of the latter. On the other hand, hydronaphthol is non-irritant, non-poisonous, and non-corrosive, and, although only soluble in water to the extent of one part in one thousand, in this proportion is antiseptic. It has no odor to disguise that of putrefaction, nor is it decomposed or rendered inert by the products of putrefactive decomposition—such as sulphureted hydrogen, ammonia, etc. It is far more stable than carbolic acid, not being volatile at ordinary temperature. Its vapor, when volatilized for purposes of fumigation, has no obnoxious effect upon the organs of respiration. It will not injure, either in substance, solution, or vapor, colors or textile fabrics. Its sparing solubility in water is rather an advantage than otherwise, as mistakes in making solutions can not occur. A saturated solution is about of the strength of one to one thousand, and in this proportion it will perfectly preserve for an indefinite time animal tissues and fluids, and yet upon living tissues this solution produces no perceptible effect other than the formation of a very slight albuminate film—this latter to be considered rather an advantage than otherwise, inasmuch as it constitutes an additional security against infectious germs floating in the air. If for no other reason than that it is non-corrosive, and hence will not injure the polished surface and keen edge of cutting instruments, it is to be preferred to mercuric bichloride, and to the latter it is second only in antiseptic qualities. It has a slight aromatic taste and odor, and crystallizes in scale-like clinorhomboid laminæ of a silvery white or grayish hue. Although but sparingly soluble in water, it dissolves freely in alcohol, ether, chloroform, glycerine, benzole, and the fixed oils. It is not volatile at ordinary temperature, but begins to sublime at about 90° C. With the alkalies and the alkaline earths it forms compounds which are unstable, are readily decomposed by carbonic acid, and of doubtful antiseptic value. It is easily powdered, and in this condition, triturated with carbonate of magnesia, silicates, such as fuller's earth, China clay, etc., in the proportion of two parts of the hydronaphthol to one hundred of either of the above named, can be dusted along the line of incision and over the mouths of drainage-tubes, in the latter application having an advantage over iodoform, now so commonly used for that purpose, in that it does not dry up the serum escaping from the wound cavity and thus block up the exit extremity of the tube. Absorbent gauze, cotton, jute, wood flour, sawdust, peat, moss, and paper-wool may be impregnated with it by immersing them in its alcoholic or benzole solution and then drying, the hydronaphthol crystals cling to these without the aid of stearin, paraffin, or resin, as in the case of carbolic acid. As it is not decomposed by the presence of organic matter, it possesses this advantage over corrosive sublimate in the preparation of surgical dressings. Its ten per cent. alcoholic solution perfectly sterilizes silk, and sufficiently hardens and preserves, as well as sterilizes, catgut.—*New York Medical Journal*, October 3, 1885.

MEDICINE

Periostitis of the Spine, with Tetanic Spasms —Dr Wm Budd, of Exeter, reports the following case R M , a gentleman of active habits, had been affected for the last nine months with symptoms of periostitis The spine and the bones of the pelvis were the parts chiefly affected When he consulted me, there was much tenderness on the spinous processes of the third and fourth dorsal vertebræ and also on the sternum He had also suffered from severe pains in his limbs and trunk generally, which the least motion aggravated, coughing, sneezing, or laughing produced agonies of pain in the back and ribs The pains were greater at night A few days before applying to me, a new symptom came on He became affected with sudden attacks of tetanic spasms, which fixed his limbs and extended his trunk, throwing his head back It was a sudden shock, which relaxed again instantly He found that the best way to avoid their recurrence was to lie on his back, and remain perfectly still On inquiring into his past history, he told me he had had a sore on his penis seven years previously, accompanied by bubo, which was followed by nodes on the shin bone He experienced salivation from the treatment received at that time Feeling sure that his symptoms were a manifestation of the syphilitic virus, I ordered him a mixture containing five grains of iodide of potassium, and five grains of Plummer's pill every night at bedtime After taking these for a fortnight, he was greatly relieved in all his symptoms The tetanic spasms had not returned since taking the medicine A fortnight later he was entirely relieved from his symptoms, and had gained strength and flesh The next time I saw him, he expressed himself as perfectly cured —*British Med Journ* , Sept 26, 1885

SURGERY

Gangrene of the Lung —In a paper on the subject, read at the recent annual meeting of the British Medical Association, Dr Sidney Coupland says Examining the *post mortem* records of the Middlesex Hospital for the ten years 1875-85 (*vide* Table), I find thirty-eight cases of pulmonary gangrene which passed on to the stage of excavation, in cases where a more or less extensive sloughing of lung tissue had taken place, with the formation of one or more cavities I have excluded lobular suppuration and bronchiectasis from the category, except where the latter has led to a gangrenous condition Of these thirty-eight cases

14	were	associated with	acute croupous pneumonia
6	“	“	chronic pneumonia
2	“	“	bronchiectasis and chronic pleurisy
3	“	“	pulmonary embolism
1	“	“	pulmonary thrombosis [1]
4	“	“	cancer of the tongue
3	“	“	cancer of the œsophagus
2	“	“	cancer at the root of the lung
1	“	“	thoracic aneurism
1	“		cerebral hemiplegia
1	“	“	suppurating bronchial glands and tuberculosis

The relationship between gangrene of the lung and acute lobar pneumonia has hardly as yet received satisfactory explanation Laennec considered that the surrounding inflammatory change was purely secondary, and there is no doubt much truth in this view as regards many cases But there yet remain a fair proportion where there seems no room for questioning the fact that acute pneumonia has terminated in gangrene Of the fourteen cases mentioned as associated with acute pneumonia, not more than eight could fairly be considered as directly dependent on the latter In the rest, the limitation of the pneumonic areas, distribution of the gangrenous foci, point to the hepatisation being secondary to the gangrene At the same time, no adequate cause for the occurrence of the gangrene can be assigned

That some cases of pneumonia occurring in debilitated subjects, or in those who are the victims of depraved nutrition, may eventuate in gangrene, cannot be denied Thus, in six of these cases, there was an admitted history of alcoholic excess, three cases were complicated with granular kidney, and one occurred in a diabetic, but what is the precise determining factor of the gangrenous process in these cases, I am unable to say One can, of course, assume that, in all these subjects, as in those where no underlying cachexia is present, there may be such an extension of the inflammatory process as to involve the nutrient vessels of the organ, presumably the bronchial arteries, but we have no actual demonstrations of this fact, and I cannot help suspecting that in most if not all such cases, there has been admitted into the lung some special irritant or septic material which has initiated the virulent type of gangrenous inflammation The rarity with which gangrene occurs as a sequel of acute pneumonia, is well illustrated by the returns furnished last year to the Collective Investigation Committee of this Association Out of the 1,065 cases so returned, gangrene resulted in only two, both being old subjects, and one a drunkard In a certain number of cases, however, the connection between pneumonia and gangrene is more evident I refer to those cases of lobar inflammation which, instead of resolving, pass into a condition of induration, where the pulmonary tissue becomes converted into a dense more or less vascularized tissue, or portions and tracts of the inflamed lobe may remain so consolidated

He gives a table of twenty cases of gangrene of the lung associated with pneumonia The seat of the gangrenous cavity or cavities was in the right upper lobe in no fewer than eleven cases, and there was no single instance of the left upper lobe being implicated In three cases, the gangrene was in the right lower lobe In two cases, gangrenous foci were found in both lungs, namely, in the right lower lobe and left upper lobe in one, and in the converse lobes in the other

The condition of the overlying pleura is important, especially in view of the practicability of puncture in such cases The pleural sac was obliterated by firm adhesions over the affected lobe in six of the cases associated with acute pneumonia, and in all those in which the pneumonia had become chronic But in one of the latter, the line of adhesion was not completely conterminous with the limits of the gangrenous cavity, and the puncture which was made in this case resulted in a pyo pneumothorax In four of the acute cases, there was more or less abundant lymph in the pleura covering the affected lobe, and in two there was empyema, apart from any perforation of the pleura Lastly, in two cases there was very slight, or hardly any, concomitant pleurisy

---

[1] Pulmonary thrombosis occurred in other cases but in only one could it be considered as in any way causally related to the gangrene In most cases the thrombosis was clearly secondary

In another class of cases, gangrene of the lung can be traced more clearly to blocking of the pulmonary vessels, but it is noteworthy that such local arrest of the circulation does not necessarily lead to gangrene, although it may often be productive of that form of necrosis known as the hæmorrhage infarction These infarcts, common in cardiac disease, do not, as a rule, break down by gangrenous softening, in spite of the access of air to their vicinity The ultimate issue of pulmonary infarcts is mostly caseation and shrinking of the necrosed part

When we have excluded from the list all those cases of pulmonary gangrene which may fairly be attributed to antecedent pneumonia, to thrombosis or septic embolism, we have by no means exhausted the whole etiological category, for, although we are practically reduced to cases where putrescent material gains direct entrance into the lung by inhalation, we find that this may be brought about under a great variety of circumstances Indeed, I am not sure but that a closer scrutiny of many a case of so called pneumonic gangrene may show it to be owing to the entrance into the lung by inhalation of putrefactive germs, and that, as I have before stated, there may be more truth than we are inclined to admit in Laennec's original view of the relation between the gangrenous focus and the concomitant pneumonia[1]

The putrefactive materials so inhaled may be found in (1) retained bronchial secretion, (2) morbid extrapulmonary products, and (3) foreign matter introduced from without

After giving a history of the surgical treatment of pulmonary gangrene, he says That pulmonary cavities may be laid open and drained, without, in many cases, incurring much risk, has been amply demonstrated of late years Most of the operations have been of a palliative rather than a curative character, dealing with basic bronchiectatic cavities or phthisical vomicæ Of such, I do not desire now to speak The operation of tapping a chronic pulmonary cavity is simplified by the almost invariable circumstance of a thickened and adherent pleura, and if the physician can be sure of his diagnosis of the presence of a cavity, the surgeon has few difficulties to encounter in reaching it It is, however, in cases of pulmonary gangrene that we should look for more permanent and satisfactory results of such operative interference were it not that it is precisely in these cases that most difficulties are present It is impossible to determine by the prevailing methods of physical examination the extent or depth of a gangrenous focus, or even whether it has reached the stage of excavation, that is of demarcation and detachment of the slough, or to be certain that one is dealing with a small circumscribed area of gangrene rather than a diffuse necrosis, limited only by the natural boundaries of the implicated lobe Nor can we determine the very important question of the presence or absence of pleural adhesions The case with which this paper opened bears out these discouraging reflections In another case (No 20) the diagnosis of the seat of a circumscribed gangrenous cavity was correct, but the introduction of the trocar was followed by pneumothorax After death it was found that the artificial opening had been made into the lung just along the line where the pleural layers ceased to be adherent Had the opening been half an inch higher, it would have escaped the pleural sac The absence of adhesions is, *cæteris paribus*, more probable in the case of acute than in that of chronic gangrene, but the risk of inducing pyopneumothorax must be balanced against the almost inevitably fatal issue of the case if not treated surgically Should the pleura be opened, the case would have to be dealt with as one of fœtid empyema, and measures be taken to drain the pleural sac At the same time, in acute cases one would be guided rather by the general condition of the patient, before advising operation, knowing that recovery under expectant treatment sometimes occurs When gangrene of the lung complicates malignant disease, or thoracic aneurism, it is futile to think of surgical measures But in chronic cases, not so complicated, not only are pleural adhesions probably present, but the sloughing mass is likely to be circumscribed It is in such cases, and especially in those where the gangrenous process has been set up by the presence of a foreign body in the bronchus, that one may look for the most satisfactory results, when indeed, a recourse to surgical interference appears to be not only justified, but to be the only rational line of treatment At present the subject is too novel to allow any definite rules to be formulated, but enough facts have already been gathered to point to a line of successful treatment of one of the most distressing, and, hitherto, one of the most hopeless of diseases —*British Medical Journal*, September 5, 1885

HYPODERMIC INJECTION OF PILES—DR J W GIRARD, of Winchester, Tennessee, says "If my experience with the use of the hypodermic syringe in hæmorrhoids be worth anything to the profession, I give it cheerfully I have used it for about ten years, and have treated, I think, about 200 cases without a single failure, and in no case has the tumor returned thus far My course of treatment is generally to take one part of tannic acid, two parts of carbolic acid, four parts of alcohol, and eight parts glycerine I inject each pile separately, and, in a few days, they slough away, and generally heal kindly under dressings of carbolated cerate If there be much constitutional disturbance, I generally control it with a steam bath or a hot sitz-bath "—*British Medical Journal* Sept 5, 1885

---

[1] At the present time when evidence is accumulating in favor of acute lobar pneumonia being due to the presence of a specific microbe (Friedländer's Pneumococcus) there is less ground for opposing the doctrine above stated Nevertheless I should not be prepared to admit that every case of pulmonary gangrene can be explained in this way

PNEUMATIC DIFFERENTIATION

The article by Dr Houghton, which appears in this issue of the Journal, is the fourth and last contribution upon the merits of the Cabinet known by the rather cumbrous name of "Pneumatic Differentiator" Dr Herbert F Williams, of Brooklyn, brought it to the notice of the profession at large by a report in the *New York Medical Record*, Jan 17, 1885, of its trial in sixty-four cases of various pulmonary complaints He subsequently discussed its action and limitations before the Climatological Society at its meeting in New York last Spring A report of his paper, together with remarks upon it by Drs Armour and Loomis, may be seen in the *New York Medical Journal* of Oct 3, 1885 In the columns of the Journal of Aug 1, 1885, is an article by Dr Vincent Bowditch, of Boston, wherein he reviews the subject of pneumatic therapeutics and cabinets and the Differentiator greatly to the advantage of the latter Dr Houghton's paper and an editorial comment in the Journal of Feb 14, current year, complete, we believe, the literature upon this subject up to the present time

The Cabinet possesses decided merits as will be seen by the perusal of Dr William's reports In our comments last February we took the view that it is practically the same in its effects as the administration of compressed air, and from further reflection, as well as personal investigation of the cabinet, we see no reason to change our opinion However, there is one respect in which the "Differentiator" is certainly superior to all portable air condensing machines This is the facility and thoroughness with which medicaments can be carried into the lungs Were this the sole merit of the Cabinet, it would be of value, but since it promotes a better expansion of the chest in individuals of the superficial respiration, it thus constitutes a powerful means for the prophylaxis of tuberculosis Yet this is not all, as shown by the report of cases by Drs Williams and Houghton, the use of the Cabinet confers permanent benefit in non tubercular catarrhal conditions of the bronchial mucous membranes, as well as in atelectasis and compression of the lungs In pulmonary tuberculosis improvement generally results, while in a few cases, as reported by Dr Williams, there seems reason to believe that the process has been arrested It is thus seen that the Differentiator accomplishes all that has ever been claimed for compressed air Indeed it is not unreasonable to predict that, owing to its superiority in the thoroughness with which atomized solutions may be carried into the lungs, even more brilliant achievements may characterize its employment As in the inhalation of compressed air, not the least important of its benefits is its ability to check hæmoptysis, and herein, as well as in all other respects, the similarity of its action to that of compressed air is presumptive evidence that Pneumatic Differentiation is but a method of administering air under increased pressure, and a few moments' reflection will suffice to convince any one that such is the case We may therefore with propriety apply to Pneumatic Differentiation Waldenburg's explanation of the effects of his apparatus

He describes the effect of respiration upon the heart and arterial system as follows In consequence of negative pressure within the lungs, the primary effect of inspiration is an aspirating one upon the veins of the body Their contents are emptied into the right side of the heart, and this organ contracting with diminished vigor, throws but a small amount of blood into the aorta, and blood pressure within that vessel sinks As soon, however, as atmospheric pressure in and out of the lungs becomes equal, all suction force upon the veins ceases, until at the close of inspiration and during expiration, positive pressure is exerted upon the heart and aorta The ventricles contract energetically, but receiving less blood they force less into the great vessels Hence, during expiratory effort arterial tension is increased When compressed air is inspired, its inrush is so sudden that an aspirating effect upon the veins is not exerted, the lungs quickly become distended, the veins of the neck grow turgid, and owing to the pressure exerted upon the heart and great vessels, arterial tension is increased, the same as in expiration As this pressure persists during the ensuing expiratory effort, the effect of compressed air is the same as, and prolongs that of expiration.

In consequence of the alveolar distension, caused by the inspiration of condensed air, the pulmonary capillaries are subjected to a degree of pressure which partially exsanguinates them. This anæmia of the lungs, which, according to Jaccoud, is likewise produced through the rarefied atmosphere of high elevations, directly favors the arrest of pulmonary hæmorrhage and engorgement, precisely the effect claimed by Drs. Williams and Houghton for their system of pneumatic therapeutics. But the beneficial influence of such a treatment is not merely local, there are constitutional effects which can be understood only by a knowledge of certain changes that take place in the arterial system. What Sommerbrodt says with reference to this, seems to us particularly satisfactory. An increase of the intra-bronchial pressure, according to that observer, whether from coughing, loud talking, laughing, and the like, the Valsalvan method, or the inhalation of compressed air, stimulates the sensory nerves of the lungs, hence ensue, by a secondary reflex action, stimulation of the vaso-dilator nerves, lowering of arterial *tonus*, increase of the pulse rate and fall of blood pressure. At the same time also results a reflex lessening of the inhibitory influence of the vagus, the circulation is quickened and the secretion of urine is augmented. The teleological significance of all this is, that an increase of oxygen and nutrient material is supplied to the muscles concerned, and probably to the brain and nerve centres. In this reflex effect upon the systemic circulation to which much of the constitutional benefit of ærotherapeutics must be ascribed lurks a danger which must not be overlooked. If the arterial coats be atheromatous, the dilatation of the vessels, which is meant to counteract the increased blood pressure, cannot take place sufficiently. Not only might rupture of an artery occur, but the strain thus imposed upon a weak heart might occasion its sudden failure. Owing to this and other dangers liable to follow its employment in the hands of ignorant or careless men, the Cabinet under discussion should be kept out of reach of charlatans, and we are glad to learn that measures to this end are adopted by the company controlling its manufacture. Only regular and reputable physicians are to be entrusted with the use of the Cabinet, at a yearly rental of $250, as the machines will not be sold. We should be pleased to see Pneumatic Differentiation become widely adopted for the treatment of pulmonary diseases, but fear the rental required for the apparatus will militate against its acquisition in more than exceptional instances. We understand that five Cabinets are already in use in Brooklyn, three in New York, one in Boston, one in Albany and one in Cincinnati. The recent improvements in its construction have made it easy of manipulation and efficient. We commend Dr. Houghton's Cabinet to the unprejudiced inspection of our readers who reside within easy access.

"A NEW AND RELIABLE SIGN OF PREGNANCY."

Contributions to our knowledge of the signs of pregnancy, especially those developed during the early months, are of peculiar interest and importance. Dr. Reinl, of Franzensbad, called attention in the *Prager medicinische Wochenschrift*, 1884, No. 26, to a new and reliable sign of pregnancy, observed and described by Professor Hegar. Dr. P. Compes, assistant physician in the Freiburg obstetrical and gynecological clinic, in a recent communication to the *Berliner klinische Wochenschrift*, 1885, No. 38, confirms the observations of Professor Hegar and Dr. Reinl.

This sign consists in softening and compressibility of the lower uterine segment, in marked contrast with the firmer and thicker tissues of the cervix. The softening and compressibility of the lower uterine segment are more pronounced in the median section than towards the borders. In order to elicit this sign at the earliest possible period, Dr. Compes recommends the combination of the rectal touch with abdominal palpation in the following manner:

The index finger of the left or right hand is introduced into the rectum, after the thumb is inserted into the vagina and placed upon the vaginal portion. The index finger, pursuing a backward direction, seeks to penetrate the aperture of the *sphincter ani tertius*, to do this, the sacro-uterine ligaments, marking the boundary between lower uterine segment and cervix, must be passed. When it is not easy to execute this manœuvre, as not infrequently is the case, since the aperture of the *sphincter ani tertius* may be concealed, placed to the right or left, or very narrow and situated posteriorly, one-quarter litre of lukewarm water may be allowed to run into the rectum. It will be an easy matter, now, to find the aperture. Then let the hand lying upon the abdomen, above the symphysis, press downwards and backwards in the direction of the index finger, moving in the rectum upwards and forwards. The index finger examines first the cervix and then the lower uterine segment. The manipulation may be rendered still easier by grasping the vaginal portion with a double tenaculum. It is not necessary to anæsthetize the patient.

The presence of this sign has been demonstrated as early as the end of the seventh week Its diagnostic value is not definitely settled Dr Compes thinks it is a positive indication of pregnancy, since he has not observed its presence in a great variety of pathological conditions of the uterus, nor in the puerperal uterus However, changes similar in kind, less in degree, have been noticed in isolated cases of retroversion of the uterus Then the softening and compressibility of the lower uterine segment is not observed in every case of pregnancy Further investigation is necessary to determine the exact significance of these changes

Their origin is clearly explained by Bandl's researches into the anatomical boundaries of the *cervix uteri* • Bandl (*Archiv fur Gynakologie, Band XV, Heft 2*), is convinced that the lower uterine segment is the *collum uteri* The supravaginal portion of the cervix is much thinner than the *corpus uteri* The changes in firmness and compressibility in the lower segment as observed by Hegar, Reinl and Compes, are due to the alterations about the internal os, when the cervical canal is beginning to be drawn up into the uterine cavity

Dr Rasch (*British Medical Journal, Vol ii, 1873*) describes a sign of pregnancy,—the detection of fluctuation through the anterior uterine wall, depending upon the presence of liquor amnii,—which is not identical with the phenomena noticed by Hegar Uterine fluctuation may be detected as early as the end of the eighth week

PROFESSOR MATTHEW HAY

We learn that PROFESSOR MATTHEW HAY, of Edinburgh, has been elected Professor of Pharmacology in the Medical Department of Johns Hopkins University Though we have no intimation that he has accepted, or that he will accept, we are sure that those who desire to see a higher medical education in this country, and especially those who can appreciate the benefits of a correct and thorough teaching of Pharmacology, sincerely hope that Prof Hay will consent to come to America, to teach in what promises to be one of the most thorough medical schools in the world

Professor Hay is yet a young man, but he has earned, by hard and thorough work, a very enviable reputation as a pharmacologist and teacher We can but think that his coming to America would be greatly to his advantage The field for pharmacological work in this country is vast, and his acceptance of the position offered him would in all probability awaken an interest in the subject, that has thus far been unfortunately almost foreign to America His work has been no small factor in creating the demand for better pharmacological work in Great Britain, a demand that has recently been manifested by the establishment of a Section of Pharmacology in the British Medical Association Much as has been and will be said against "Specialism," it must be admitted that this important branch—or study must be taught by a "Specialist" Good work in pharmacology must be done by one who has a special training and a special aptitude for the work, and further, he must be a chemist and appreciate the value of physiological pathology More attention to pharmacology, therefore, means more attention to and better work in medical and physiological chemistry and physiological pathology It may be said that America offers better advantages now to the pharmacologist and physiologist than does England, since the anti-vivisection element here is not so strong—nor is it likely to become so powerful and rabid The most that that element can hope for in this country is a restrictive law which will be entirely satisfactory to the physiologists, and to which they will give their full consent

SMALL POX AND VACCINATION

Perhaps nothing has occurred in recent times, better calculated to impress the minds of both the profession and the people with the inestimable value of vaccination as a reliable preventive of small-pox, than the unusual prevalence of the latter disease in the city of Montreal Having a considerable percentage of her population not only unvaccinated, but by prejudice and want of knowledge stubbornly opposed to being vaccinated, the result has been that the small-pox, once introduced among them, has already destroyed several hundred lives, interfered with business to the extent of millions of dollars, and is said to have added at least half a million to the city's debt And yet these are only a part of the evils produced, for the protracted and extensive ravages of the disease in that city has endangered the carrying of the contagion in persons and clothing into all other parts of Canada, and into all the States adjacent thereto Indeed, it has been carried into, and manifested the disease, in several places within our States already, and had the people generally been as negligent of, or as prejudiced against, the practice of vaccination, as a part of the citizens of Montreal, the small-pox would now be prevailing in all its loathsome destructiveness in a dozen States of our Union But by the vigilance of the State and Local Boards of Health in New England, New York, Michigan, Wisconsin and other States, the disease has thus far been restricted to the parties bringing it within our borders, and there is a strong probability that it will remain thus restricted Yet it is the duty of every citizen to see that not only himself, but his family and his employes are as well protected as vaccination can make them

SOCIETY PROCEEDINGS

OBSTETRICAL SOCIETY OF PHILADELPHIA

Stated Meeting, Thursday, October 1st, 1885

The President, B F Baer, M D, in the Chair

Dr Wharton Sinkler read a paper on

THE DIFFERENT FORMS OF PARALYSIS MET WITH IN YOUNG CHILDREN

The most frequently met form is infantile spinal paralysis, or *polio-myelitis anterior* This term indicates the pathology of the disease, which is an inflammation of the nerve cells of the anterior horns of white matter of the spinal cord This affection may come on at any period of life, but is generally seen in children and usually at the age of two years

The children are generally strong and apparently healthy, and the paralysis is sudden in its onset Fully two-thirds of the cases I have seen have been attacked in the summer months, hot weather and teething seeming to be predisposing agents Dr Barton, of Manchester, England, reports that of fifty-three cases in which he noted the time of onset, twenty-seven occurred in July and August The attack is preceded by fever of greater or less intensity, with pain in the head and limbs, with general soreness when moved or lifted After a few days, paralysis more or less complete occurs, but in a few days a regression of the paralysis from some of the affected parts occurs Sensation is undisturbed Atrophy of the muscles is soon apparent, in fact, the paralyzed portion stops growing for a time The temperature of the affected portion is low and the skin is blue and mottled, but there is no tendency to ulceration, and wounds or scratches heal readily The skin and tendon reflexes are lowered or abolished in the affected limbs At first response to the farradic current produces but little muscular contraction, except when a powerful current is used When atrophy has set in the reaction of degeneration is seen Most cases of club foot are the result of infantile palsy Deformities of the upper extremities are rare, this disease differing in this respect from cerebral palsies The exact causes of infantile palsy are unknown Over fatigue often precedes an attack, sudden chilling is considered by Seguin to be a frequent cause

The *prognosis* as to perfect recovery is only moderately good In many cases the most faithful treatment fails to restore the paralyzed muscles, but in almost every case we can expect more or less improvement

In the early stages of the paralysis, after the subsidence of the fever, the treatment should consist of mild stimulation to the spine, ergot, and small doses of bromide of potassium should be given internally Later in the disease, iodide of potassium should be given instead of the bromide When the palsy is established, electricity and massage are the means to be depended upon They must be persisted in for months or even for years Internal treatment is of little or no value unless there is some failure in the general health of the child

Spasmodic paralysis as seen in children is of two varieties When of primary spinal origin, or when there is a descending degeneration of the cord from a primary cerebral lesion, there sometimes seems to be a congenital defect in the motor tracts of both brain and cord In the spinal variety there is often seen, soon after birth, rigidity of the limbs, at first this is only occasional, but as the child gets older, every effort to move a limb causes muscular rigidity in it The child does not attempt to walk until three or four years of age Then when it is supported under the arms and it tries to stand or to walk, the movements are very peculiar and characteristic The feet are extended and inverted so that the child rests on the toes The knees are strongly adducted and lock together so that the legs become entangled By degrees the child becomes able to walk with the aid of apparatus or some form of crutch The hands and arms are often affected, and every effort causes muscular rigidity to come on The mind is unaffected in these cases, and the speech may be distinct, although it is often very defective Sensation is unimpaired, and the patella reflex and ankle clonus are exaggerated There is no wasting of the muscles By these symptoms we infer that the disease is localized in the lateral columns, but exactly what is the nature of the lesion we do not know, for no post mortem examinations have been made in these cases The cause is unknown Hamilton found three of seven cases which he had collected were premature births Adherent and contracted prepuce has been thought by some to be caused by reflex influence of the spasmodic paralysis, but operation has not given relief The treatment should consist of massage, galvanism to the spine, ergot, and cod liver oil Fluid extract of conium may be given to allay spasm In severe cases great improvement follows this treatment

Even when we can do no positive good to the limbs, very much can be effected by the aid of apparatus Properly adjusted braces to the legs will enable a child to walk on crutches or on a Durrach wheel crutch

There is a form of spasmodic spinal paralysis in which the child is imbecile In these cases there has probably been congenital defect in cerebral development The head is small and there is no evidence of intellect, often nystagmus is present

Paralysis from Pott's Disease —Paralysis of the lower extremities may result from caries of the spine The lesion may be either a meningitis or a myelitis, if meningitis alone, there is considerable pain and contraction of the legs Generally there is a trans verse myelitis. The symptoms are numbness and pricking of the legs, with loss of sensation; gradually increasing loss of power, with wasting of the muscles; incontinence of fæces with retention or incontinence of urine. Sometimes there are ulcers over the sacrum or on the limbs.

The indications for treatment are evident. An apparatus which will take the weight of the body from the spine is necessary and is sometimes sufficient of itself. Frequently, however, the application of the actual cautery over the spine brings improvement in the symptoms when an apparatus has done no good. Massage and electricity should be used to restore the atrophied muscles.

Paralysis from Rachitis and Diphtheria is seldom complete. The former is often spoken of as the the pseudo palsy of rickets. Negro children, who are very subject to rachitis in cities, often have rachitic paralysis. The child at three or four years is unable to walk or stand. Sometimes it has not sufficient muscular development to sit upright. It can move every limb and has no loss of sensation, but has no power. Cod liver oil and massage bring about the most satisfactory results in these cases. *Diphtheritic paralysis* usually begins in the muscles of the soft palate and pharynx and extends to the extremities. It is generally bilateral and incomplete, but I have seen a case in which it was hemiplegic. It is considered peripheral in character, and is believed by some to be connected with the altered condition of the blood consequent on the original attack. Diphtheritic paralysis is rarely fatal, and lasts in most cases only a few weeks, although it may continue for months. Strychnia and electricity are the means to be employed, and the case usually responds promptly to these remedies.

Pseudo hypertrophic Paralysis is a rare affection, but is of much interest. The disease belongs almost exclusively to infancy. It is characterized by muscular paralysis with great increase in the bulk of the muscles. This enlargement is due to fatty deposit, while the muscular tissue proper is atrophied. The affection begins with weakness of the legs, a peculiar balancing of the trunk and separation of the legs in walking. The shoulders are thrown far back in standing and walking. There is great difficulty in getting from the sitting to a standing position. Later in the disease the muscles become wasted and shrunken, and the general health begins to suffer. Death results from implication of the respiratory muscles. The skin is mottled like a piece of castile soap. The tendon reflexes are abolished and electro muscular contractility is impaired. There is often a greater or less amount of mental weakness. There is no loss of power over the bladder and rectum, and sensation is not affected. Heredity influences the disease, which is slow in its progress, but the course is steadily downward.

Friedreich's Disease is still more rare than the preceding. It is practically locomotor ataxia in childhood. There is evidenced here also a hereditary predisposition, and the female children seem most liable.

Cerebral Palsies.—Hemiplegia may result from some injury at the time of birth, either from the forceps or from the pressure of a prolonged labor. A child may be born hemiplegic after a perfectly natural and easy labor. Under these circumstances we must regard the paralysis as the result of imperfect cerebral development. Hemiplegia, under these circumstances is generally permanent. The side affected grows less rapidly than the other. The flexors of the arm and hand are usually contracted. The leg becomes rigid in the act of walking. Convulsion is almost always associated with cerebral paralysis, either immediately preceding the attack or occurring soon after. The convulsive movements are most violent on the side which is subsequently paralyzed. The child will have an idiotic expression and speak indistinctly, but their friends think them intelligent. The convulsions are liable to return when the child is older, and then assume and epileptic form. The walk is peculiar and is called the spastic gait; the patient plods along looking as if he were about to pitch forward. The affected limbs are smaller and shorter, the growth of both bone and muscle being affected. In the choreic variety, where the arm is in constant motion, the muscles may become hypertrophied but the bone remains short.

Prognosis.—As a rule the prospect of recovery is bad; even if the patient gets well the hemiplegic side remains awkward.

Treatment.—Cod liver oil, and massage, which always relaxes the contracted muscles. The affected limbs should be used by the patient as much as possible.

DR. R. P. HARRIS inquired if Dr. Sinkler had ever observed any hereditary predisposition to convulsions and paralysis.

DR. SINKLER replied that the hereditary influence was decided even when no convulsions occurred.

DR. E. E. MONTGOMERY reported a case

OF OOPHORECTOMY.

Mrs. L., of Columbia, Pa., æt. 36 years, married ten years, pregnant five times, the last four years ago, was brought to my office by Dr. H. T. Chase. Her health has been bad since her last confinement. First menstruation at twelve and a half years, regular and very free for one and a half years, when she fell, producing pelvic distress, after which for seven years the flow was very scanty, lasting but one or two days and accompanied by excruciating pain. She improved somewhat after marriage. Her first conception was followed by so much nausea, vomiting and anæmia that her physician advised and induced an abortion. She is now regular as to time, but irregular as to quantity; it is preceded by an excruciating pain for two days, which continues until the flow disappears; she also has severe pain in the head. She is very nervous at all times, but this is much intensified during the period. Pain is more marked in the left inguinal region and down the corresponding limb. Coition and vaginal examination are very painful. The uterus is enlarged and painful, tender on pressure over both ovaries. Local uterine treatment had been kept up during the entire four years without relief. Trachelorrhaphy had been performed. Ovariotomy was advised.

Sept. 19, 1885, she entered my private hospital, and, assisted by Drs. W. H. and C. B. Warder and E. Eshleman, the uterine appendages were removed. The left ovary was composed of a number of cysts, the largest of which ruptured while adhesions were being separated. The right ovary was not enlarged, but it was removed to ensure relief. The wound was closed with silk-gut and dressed with sublimated gauze and absorbent cotton. There was no shock. The highest temperature reached was 101.6° at midnight of the 20th, and it was normal on the 22d. Sutures were removed on the eighth day, and the wound re-dressed for the first time. It had united throughout, and there was no irritation from the sutures. The effect upon her general health remains to be determined.

Dr. Montgomery also reported a case of

SUPRA-VAGINAL REMOVAL OF THE UTERUS AND BOTH OVARIES FOR FIBROID TUMOR.

Ann H., æt. 27, was brought to me by Dr. T. H. Boysen, of Egg Harbor City, with the following history. Her menses from the beginning occurred every three weeks and were free an entire week. During the last four years they have occurred every two weeks, and are attended with pain in the pelvis and down the limbs and severe pressure upon the bladder, causing frequent urination and sometimes necessitating the use of the catheter. Dr. Boysen had diagnosticated fibroid tumor, which my subsequent examination confirmed. The tumor was the size of a child's head, filling up the pelvis and apparently arising from the anterior wall. The examination led me to believe that the bladder was adherent over the anterior surface and would render the removal of the tumor unsafe. I suggested the removal of the ovaries.

She entered my private hospital Sept. 9, 1885, for that purpose. Drs. W. H. Warder, Boysen and Martin assisted, Drs. C. B. Warder and Staltweather present. An incision three inches long was made, and finding the tumor free from the bladder, with cervix sufficiently long to serve for a pedicle, the incision was extended to within an inch of the umbilicus above and symphysis below, and the tumor with some difficulty withdrawn. In the absence of a Tait's clamp which had been ordered some days before, the pedicle was constricted by a wire-ecraseur and the tumor with the ovaries was removed. The pedicle was then transfixed with two steel pins and tied in three sections with strong silk thread. The peritoneum was fastened to the pedicle below the ligatures, and the wound closed with silk gut sutures, the pins holding the stump outside. The wound was dressed with sublimated gauze and absorbent cotton. The operation was followed by some shock, temp. 97.4, pulse 104, from which she soon rallied. She complained greatly of pain. A half-grain of morphia had been given by suppository, and three hypodermic injections of morphia, one fourth grain each, were given during the afternoon before the pain was relieved.

At 3 A. M. of the 24th I was called by the nurse, who reported bleeding from the stump. Three ounces of blood had been lost. By aid of Dr. Warder, a Wells clamp was applied below the pins, apparently controlling the hæmorrhage, but it recurred later in the day from the angles and from beneath the clamp. By this time the Tait's clamp had arrived, and the patient was etherized, the three lower sutures removed, the pedicle drawn up, the clamp applied so as to control it completely, and the wound again closed. The wound had united throughout. Temperature reached 100.6 at 9.30 P. M. The highest subsequently, 101.6, was in the afternoon of the 25th, and it became normal on the 28th. Upon removing the dressings, on the 27th, some pus welled up about the pedicle. As the skin was irritated, the dead pedicle was cut away until the clamp slipped off. There resulted, of course, considerable retraction of the stump, but the sloughed tissue is now nearly cleared away. The patient suffers no pain or discomfort, temperature normal. The tumor was situated in the anterior wall and fundus of the uterus, and projected into the uterine cavity,

Dr. Parish remarked that removal of the ovaries had given such good results in cases of uterine fibroids, and was comparatively so free from danger, that he would like to hear from Dr. Montgomery his reason for his choice of operation.

Dr. Montgomery replied that the tumor filled the pelvis and pressed upon the bladder and rectum, causing great and constant distress. As diminution of the size of the fibroid tumor is not a certain result of oophorectomy, and as all the circumstances were in favor of the major operation, he decided upon it as the best one.

THE AMERICAN ACADEMY OF MEDICINE.

Ninth Annual Session, held in New York City, October 28 and 29.

The meeting was called to order by the President, Albert H. Gihon, M. D., of Washington.

The following were

ELECTED FELLOWS OF THE ACADEMY.

Drs. S. M. Nelson, Cambridge, Mass.; J. H. W. Chestnut, Phila.; Rufus W. Bishop, Chicago; E. E. Mariott, Springfield, Mass.; George N. Acker, Washington, D. C.; H. V. Logan, Scranton, Pa.; H. W. Elmer, Bridgton, N. J.; H. F. Hansell, Phila.; E. W. Cushing, Boston, Mass.; J. S. Wight, Brooklyn, L. I.; William Osgood, North Yarmouth, Me.; C. A. Packard, Bath, Me.; W. K. Oake, Aubern, Me.; A. Mitchel, Brunswick, Me.; D. A. Robinson, Bangor, Me.; C. A. Ring, Portland, Me.; J. A. Spaulding, Portland, Me.; G. W. Marshall, Milford, Del.; Wm. A. Hugie, Charleston, S. C.; J. B. Shapley, St. Louis, Mo.; M. H. Post, St. Louis, Mo.; C. E. Briggs, St. Louis, Mo.; J. S. Alleymen, St. Louis, Mo.; N. S. Davis, Jr., Chicago, Ill., and Charles Edgar Cook, Illinois. Dr. Henry H. Smith and Dr. S. Weir Mitchell, of Philadelphia were elected to honorary membership.

Dr Robert L Sibbett, of Carlisle, Pa, read a paper on

THE STUDY OF MEDICINE AS A MEANS OF EDUCATION

He first referred to the various elements in education, considering time the most important of these The medical colleges of the United States are, he thought, institutions not to be proud of In this country 219 medical colleges have been chartered at one time and another Of this number 147 were regular Ninety three of these colleges have become extinct Of this number fifty-seven were regular Contrasting this with the situation in Canada, it is found that there only fifteen medical colleges have been chartered, and of this number twelve remain, all of which are regular At the present time there are eighty seven colleges in this country teaching rational medicine, and twenty-nine teaching sectarian medicine of various kinds The practitioners of rational medicine have no need to come in contact with the practitioners of sectarian medicine in any way In boards of health and State examining boards it is not necessary to have any association with them Taking up the subject of medical teaching, preliminary examination with graded courses and frequent examinations were heartily recommended Now a person may graduate as a Doctor of Medicine, without having even a rudimentary knowledge of grammar and arithmetic The medical colleges must take the responsibility for such graduation A protracted course of academic training is necessary for a proper study of medicine

He concluded by saying that a State Medical Examining Board with full authority to examine all practitioners, irrespective of the degrees they may hold, would do more to elevate the profession, than all other means combined

Dr C McIntire, of Easton, Pa, read a paper on

MEDICAL SUPERVISION IN STUDENT LIFE

This paper assumed that the times had changed, that modern life made a greater demand upon the time and energies of the individual to the detriment of his health and development It was considered impossible to diminish tasks and give more time to rest and recreation There is no way known to shorten the period of rest, so something should be done for recreation The plan suggested was the usual one given by students on these subjects A careful physical examination at the beginning of school life and a series of graded bodily exercise under medical supervision throughout school life was recommended Many appear to be ignorant of the end to be obtained by a modern gymnasium, so that in colleges the parents of the pupils were afraid that their children would be injured But as the weaklings are the subject of especial care and direction they are the ones least apt to be harmed and most likely to be improved The end aimed at is to give such tasks as will tend to strengthen the weaker parts

Dr Henry O Marcy, of Boston read a paper on

THE CLIMATIC TREATMENT OF DISEASE, WITH AN ILLUSTRATION OF WESTERN NORTH CAROLINA AS A HEALTH RESORT

The fundamental factors of the zymotic diseases were first reviewed from our present knowledge of the rôle of the bacteria, and the question of the wise adaptability of the individual to his surroundings was considered as the best definition of climate A *resume* of the latest investigations of climatologists was given with reference to, and the results obtained by, the mountain health resorts of Europe and America The deductions of the writer were that good must be looked for in the benefit to be obtained to the individual in the improvement of his resisting vital powers and invigoration of his cellular tissue regeneration, rather than in his escape from his bacterial enemies The larger portion of the paper was devoted to the consideration of this new and important phase of the question of climate

The higher Alleghanies in Western North Carolina were described at considerable length as offering mountain health resorts of a character well suited to a variety of diseases The deductions were based on a long tour of personal investigation made during the last summer as a sanitary study

Evening Session

The President, Dr Albert L Gihon, read his *Annual Address*, entitled

WHAT IS MEDICINE?

He said that the place of the Academy was not to be sought among the pathological, clinical, sanitary, and other national associations It antagonizes none of these, but seeks to cement all into a compact unity Referring to the slow growth of the Academy, it was stated that one of the reasons was to be found in the fundamental condition of membership, restricting fellowship to graduates in medicine who have received degrees in letters by course As the cooperation of every educated man interested in the objects of the Academy is desirable, he was of the opinion that the time had come when every limitation to fellowship should be removed except the solitary requirement that the candidate shall be in fact, as in title, "learned in medicine," and in all else that this term implies, but he would make it impossible for any one unfit or unworthy to enter, though he may come with an armful of diplomas, have subscribed to the most inflexible of codes, and no matter what faculty, society or institution he may be delegated to represent The nominations should be accompanied with the fullest record evidence, and be made long enough in advance, from six to twelve months, to enable the council to determine each man's fitness

A second reason why the Academy had not met with more pronounced sympathy and support, is its necessarily hostile attitude to institutions and individuals who defy the principles of its constitution

The Academy encounters a third obstacle in the lukewarmness of its *quasi* friends, some damning it with faint praise, others exuberant in private but chary of public endorsement Reference was made to the case of a medical editor, who could not follow his wish in this respect on account of policy The editorial columns of the medical press were preeminently high toned, but the publishers were inconsistent in permitting under the same cover advertisements of medical concerns, drug factories, and proprietary clap-trap. Why should the business venture of men who get up sham colleges be advertised in reputable journals? The *New York Medical Record* commends the recent action of the Florida Medical Association in resolving against the advisability of establishing a medical college in that State. These are encouraging signs, offsetting the fact that thirty-nine of the eighty-seven regular schools in the United States are only fifteen years old, and twenty one not over five years. Reference was made to the fact that trashy communications of illiterate men were published simply because they were subscribers. The journals only reflect sentiment. Let us ask ourselves the question, "What is Medicine?"

If we look to this Academy for the answer, we shall find that it is the most profound and ennobling study which can engage the intellect of man. This is not the popular idea, which is that medicine is only something in a box, or bottle, that is prescribed by a man or woman who has acquired more or less skill in administering the particular remedy appropriate for each disease. Like other professions whose offices are called for by the disagreeable incidents of humanity it is only tolerated as a necessity. Sham aristocrats look down upon it; others hire its members as they do their cook or cabman. In military and naval services they are sought to be degraded. The ministry of the suffering and afflicted is nowhere regarded as an outcome of the study of the stupendous and sublime mysteries of existence. In the national councils, in military and naval organizations, in civic administrations, who thinks of giving a first place to a physician, although his are the mental attainments which fit him best for counsel in all that concerns the welfare and progress of the human race. The science of medicine involves the knowledge of everything that relates, however remotely, to the existence of man, his place in nature, his origin, growth and development, preservation and continuance. The prevention and cure of those abnormal conditions which tend to his destruction, are but one chapter in the volume, which, coming near the end, can not be read understandingly without the thorough comprehension and diligent study of all that precedes. Medicine is so far reaching in its sources and so connected with every other branch of knowledge, that he who would begin its study must first have drunk deep of the well spring of human knowledge. Medicine is a science of such proportions that only a well educated mind can master it. Is this the view entertained by the profession at large? What are the facts?

Let us see how the profession is recruited. Ordinarily a youth becomes a doctor, as it were, from a whim, and there are others, no longer young, and having failed in other occupations, they hope to make money by this, knowing nothing of its responsibilities and requirements, without aptitude, ignorant, illiterate, etc. Such a one goes to a college, and as a first course student listens to lectures on anatomy, practice, chemistry, surgery, etc., one after the other, without understanding a word of the technical language. Seventy-nine colleges require evidence of preliminary education. In most this is only specious. Recent instances of illiteracy on the part of graduates are the following: "Colume of murcury," "cours at Beleview," "anylitic," "assend," "admition," "diameter of the earth ninty-two thousand miles," "the field of the cloth of gold, some kind of tapestry," "an alterative acts like food on building up system, and are favored in their action by stomachic, or anything which arouses the system to action." Could the man who after graduation says "was began," and spells "gravatation, femeral, superating, corpusels," etc., have ever comprehended the language used by the teachers? Why should medicine be cheapened to every purchaser and the college debase its teaching to their limited understanding. A collection of theses presented to American medical colleges during the last five years would be more entertaining than "English as she is spoke." Only the utter ignorance of elementary chemical principles on the part of the men who study medicine, has made chemistry one of the seven chairs. It belongs to an academic course. What only can medicine be to the ignorant numbers who are annually mustered into the ranks of the profession? To these men, it can have no other aspect than that of a trade. Many enter upon it as a money making vocation. It was taught them as a source of pecuniary profit, and they practice it for the fees they get. Manifestly, then, medicine is not the same to all men, even medical men. If improper men can be excluded from national services, why not from State, county and city medical societies? This should be done for the protection of the community. Where a drug clerk kills one victim by his carelessness, he saves a hundred by recognizing errors in physicians' prescriptions. (Examples from apothecaries' files were given.)

The debasement of medical education to the capacity of the ordinary purchaser of a diploma, will eventually cause the profession to deserve the reproaches of its friends. The public gauge the profession by the men with whom they most frequently come in contact. The wise physician does not hesitate to say "I do not know." The typical doctor affects an omniscience in adverse ratio to his knowledge. Until the mystery of the first departure from health is made clear, all our therapeutics must be empirical, and fundamental methods of cure be speculative. If we have not learned where disease begins, we have at least learned that the follies and weaknesses of men have in their wake a multitude of ills, and these we can prevent, and the wise physician, learned in all that pertains to the normal life of the body, aims to protect it from these evil influences, which his experience has taught him will do it harm.

Preventive medicine has at last attained recognition as the highest aim of the physician's art. It establishes new relations of the physician to the social system. It is not creditable to the intelligence of the age that in the department controlling internal affairs, among bureaus of labor, statistics, agriculture, education and so on, there is no bureau of public health. Preventive medicine has more to do than warding off epidemic visitations of great scourges. Its most important duty is to consider the impairment of health of growing children through the sanitary defects of our school system, the prevention of insanity, the repression of crime. It is too much to expect antidotes for every microscopic germ. The tiny swarms around us are at once our friends and foes. If we do not antagonize them, they purify the air we breathe, the water we drink, the dirt we tread, and prey upon our natural waste. It is only our own folly that causes them to turn and rend us. We are too prone to hasty generalizations. We inconsistently denounce the doctrinaires, who affect to believe in the panegyric virtue of similars, and ourselves find cure-alls in quinia, cocaine, germicides, etc. Hence the greater need of impressing upon the tyro in medicine the fact that there are underlying principles never to be lost sight of. The chair of Institutes of Medicine has gradually been supplanted by that of Principles and Practice. If he were to banish chemistry and physics from medical colleges, he would establish a chair of the Philosophy of Medicine, to include the history of medicine, medical literature, medical jurisprudence and medical ethics.

Reform has been hampered by adherence to existing methods. It will not do merely to establish adjunct chairs. The starting point must be the requirement of a thorough preliminary education. Four annual terms are necessary. Descriptive anatomy and materia medica are enough for the first year. Histology and practical microscopy, physiology in all its relations, and the mechanical processes of pharmacy should occupy the second year. Hygiene, general pathology and general therapeutics for the third year. Special pathology, special therapeutics, the philosophy of medicine, medical history, jurisprudence and ethics for the fourth year. A fifth year may with advantage be devoted to clinical experience under supervision. Medicine has no need to rear its superstructure on any other foundation than the broad basis of fact.

(*To be concluded.*)

STATE MEDICINE

THE MEDICAL BILL AS CONSTRUED BY THE ATTORNEY-GENERAL OF INDIANA

The Right to Engage in the Practice of Medicine Subject to Such Restrictions as the Legislature may Reasonably Impose.

In answer to questions submitted by Dr. Metcalf, Secretary of the State Board of Health, of Indiana, the Attorney General has given the following elaborate opinion:

ATTORNEY GENERAL'S OFFICE,
INDIANAPOLIS, June 25, 1885.

Dr. C. N. Metcalf, Secretary of State Board of Health.

Sir—You submit to me the following questions, and solicit answers thereto:

1. "Can the General Assembly enact a law to regulate the practice of medicine?"

The right of every person to pursue any lawful calling he may see fit, and to do so in his own way, not encroaching on the rights of others, is recognized in this country, subject to such restrictions as may be deemed necessary for the public welfare, and none other. (Ex-parte Spinney, 10 Nev. 323, 334.)

The General Assembly may require the possession of certain qualifications to entitle a person to pursue the medical profession.

The right to reasonably regulate the practice of medicine rests on the police power of the State, which extends to the protection of the lives, limbs, health, comfort and quiet of all persons within the State. It subjects persons and property to burdens and restraints, in order to secure the general comfort, health and property of the State. (Cooley Const. Lim., Side page 572, 573, 574.)

The vocation of the physician is laudable and lawful, and the right of any person to engage in it is subject to such restrictions only as the Legislature may reasonably impose, in the exercise of its general police power. Laws of this kind have been sustained by the courts, and held to be constitutional.

Q. 2.—"What constitutes a reputable Medical College under Section 2 of the statute, and what evidence is required thereof?"

Section 1 and 2 of said statute are as follows: Section 1, "Be it enacted by the General Assembly of the State of Indiana that it shall be unlawful for any person to practice medicine, surgery or obstetrics in this State without first obtaining a license so to do, as hereafter provided."

Sec. 2. "Any person desiring to practice medicine, surgery or obstetrics in this State, shall procure from the Clerk of the Circuit Court of the county wherein he or she desires to practice, a license so to do, which license shall be issued to such person only when he or she shall have complied with the following conditions, to wit: When such applicant shall file with such Clerk his or her affidavit, stating that such applicant has regularly graduated in some reputable medical college, and shall exhibit to such Clerk the diploma held by such applicant, or when such applicant shall file with such Clerk his or her affidavit, and the affidavit of two reputable freeholders or householders of the county, stating that he or she has resided and practiced medicine, surgery and obstetrics in this State continuously for ten years immediately preceding the date of the taking effect of this act, stating particularly the locality or localities in which he or she practiced during such period, and the date and length of time in each locality, or when such applicant shall file with such Clerk his or her affidavit and the affidavit of two reputable freeholders or householders of the county, stating that he or she has resided and practiced, medicine, surgery and obstetrics in this State continuously for three years immediately preceding the date of the taking effect of this act, stating particularly the locality or localities in which he or she practiced during said period, and the date and length of time in each locality, and that he or she had prior to said date attended one full course of lectures in some reputable medical college. Such applicant shall pay to such Clerk for such license the sum of $1 50, and such Clerk shall record such license, together with the name of the college in which such applicant graduated, and the date of his or her diploma, in a book to be kept for such purpose, and which shall be a public record ”

1 No particular school or system of medical practice is preferred by the law, and no rights are conferred upon one not accorded to all, and a practitioner in his treatment is to be tested by the general doctrines of his school, and not by those of other schools and systems of medicine

All recognized schools and systems of medicine stand equal before the law and equally reputable The statute does not require the medical college to be incorporated from which the certificate or diploma is derived (Holmes vs Holde, 74 Me , 28–38)

Every institution, whether incorporated or unincorporated, organized in good faith for scientific instruction in medicine, surgery or obstetrics, and in which such scientific instruction is systematically imparted, without regard to the school of medicine under whose control or management it is, is a reputable medical college within the meaning of the statute

The graduation in, and diploma from a college, referred to by said statute, are not limited to an institution within the State of Indiana, or the United States

2 Under the statute, when an applicant shall file with the Clerk his or her affidavit, stating that such applicant has regularly graduated in some reputable medical college, and shall exhibit to such Clerk the diploma held by such applicant, it becomes the duty of the Clerk to issue to such applicant a license to practice his profession This is the only condition prescribed by the statute, and the officer can not require more from such applicant

Q 2 —“ Will the physician holding a certificate of membership of fifteen years standing in a Homœopathic Medical Society of another State, and has had ten years, though not continuous, practice in Indiana, be entitled to a license to practice medicine in Indiana?”

A certificate of membership in a medical society confers no rights under the statute The statute requires the Clerk to issue a license to three classes of physicians

1 Where the physician has graduated in some reputable medical college, and has received a diploma

2 Where he has resided and practiced medicine, surgery and obstetrics in this State continuously for ten years immediately preceding the date of the taking effect of the statute

3 Where he has resided and practiced medicine, surgery and obstetrics in this State continuously for three years immediately preceding the date of the taking effect of this act, and has attended one full course of lectures in some reputable medical college The letter of the statute requires the applicant to have resided and practiced medicine, surgery and obstetrics in this State continuously for ten years A similar statute has been sustained and held to be constitutional

The letter of our statute also requires the applicant to have practiced medicine, surgery and obstetrics in this State continuously for ten years, immediately preceding the date of the taking effect of the statute In Wert vs Clutter (37 Ohio St , 347) it was held that such ten years of continuous practice may embrace time since as well as before the taking effect of the statute, but the statute in Ohio is unlike our statute on this subject

In ex parte Spinney (10 Nev , 323) Beatty, J , held “that there is some reason for requiring ten year’s practice in this State as a qualification for the continued practice of medicine and surgery, but there is no sort of reason for requiring that practice to have extended over the particular ten year’s ‘immediately preceding the enactment of the law,’ and to this extent the law is unconstitutional To so decide, however, would leave a good and perfect statute, omitting only the words ‘next preceding the passage of this act’ ” In this latter proposition there was no concurrence by the other Judges, but Hawley, C J , held said clause to be constitutional, and it is proper to follow the letter of the statute, which declares that the applicant must have resided and practiced medicine, surgery and obstetrics in this State continuously for ten years, immediately preceding the date of the taking effect of the statute, before a license may be issued The term “continuous practice,” in the sense of the statute, does not mean constant practice, never ceasing

It is not necessary that a physician should have a patient each day during the ten years immediately preceding the operation of the statute to have been in continuous practice and to obtain a license

No criterion can be established on the basis of the quantity of business enjoyed by a physician to determine whether he has or not continuously practiced his profession for said time

If for said time the practice of medicine, surgery and obstetrics has been his profession and business, and he has not wholly abandoned it for another occupation, and he has practiced his profession as often as he has had requests and occasion to do so, I think he may be deemed to have continuously practiced medicine, surgery and obstetrics for ten years immediately preceding the operation of the statute, and is entitled to a license

Q 3 —“ Is a certificate of membership from either State Medical Society of this State sufficient to entitle the holder to a license to practice medicine in the State, provided the holder has never attended a medical school, and has not been in continuous practice in the State for ten years previous to the taking effect of the medical act?”

A —No

Q 4 —“ Does the statute apply to a person who undertakes to cure diseases by manipulating the patient’s body, by rubbing, kneading and pressure?”

A —The statute applies to persons desiring to practice medicine, surgery and obstetrics only, and it ought not to be so construed as to cover persons not substantially within its terms

In Wert vs Clutter, supra, the Court says ‘ This statute was not intended to create a right in anyone to practice medicine It was simply intended to prohibit the exercise of the right (which before was universal) by unqualified persons. The right remains in all persons, except those from whom it is taken away by the statute."

In Bibber vs. Simpson (59 Me., 181) suit was instituted for $51 for services rendered the defendant's intestate, at his special request, by the plaintiff as a clairvoyant.

It appeared from the plaintiff's testimony that she professed to be a clairvoyant, that when asked to examine the patient she saw the disease and felt as the patient did, that sittings or seances were of different durations from one quarter to one half of an hour each, that she did not pretend to understand medicine or anatomy, that she was requested by the intestate to visit him and render him professional services, and did so as by the account, that she helped him, but he died from taking cold, acquainted him with the prices, and he agreed to pay them, but never did.

Appleton, C. J., in deciding the case, says: "The services rendered are medical in their character. True, the plaintiff does not call herself a physician, but she visits her sick patients, examines their condition, determines the nature of the disease and prescribes the remedies deemed by her most appropriate. Whether the plaintiff calls herself a medical clairvoyant, or a clairvoyant physician, or a clear seeing physician, matters little, assuredly, such services as the plaintiff claims to have rendered, purport to be, and are to be deemed, medical, and are within the clear and obvious meaning of R. S., 1871, c. 13, Sec. 3, which provides that 'no person, except a physician or surgeon, who commenced prior to Feb. 16, 1831, or has received a medical degree at a public medical institution in the United States, or a license from the Maine Medical Association, shall recover any compensation for medical or surgical services, unless previous to such services he had obtained a certificate of good moral character from the municipal officers of the town where he then resided.' The plaintiff has not brought herself within the provisions of this section, and cannot maintain this action."

In Smith vs. Lane (24 Hun., 632), Daniels, J., says: "The action was brought to recover the price which it was alleged the defendant agreed to pay the plaintiff for the treatment of himself and wife for certain bodily disabilities. It consisted entirely of manipulations with the hands. It was performed by rubbing, kneading and pressure. The evidence given by the plaintiff was to the effect that he was employed by the defendant to perform these services for a specific compensation, and that he had performed them until the amount due him was the sum of $149. Upon the close of the case on his part, the referee dismissed the complaint because it appeared that the plaintiff was not a graduate of any medical school, and had no license permitting him to practice either medicine or surgery. The direction was given because of the prohibition contained in Chapter 436 of the laws of 1874, and, as no other reason appeared in the case, or the evidence which was given that would prevent the plaintiff from recovering, and whether this act contains anything subjecting him to such disability is the only substantial point which requires to be considered in the case. The statute in terms merely declared it to be a misdemeanor for any person to practice medicine or surgery who is not authorized to do so by a license or diploma from some chartered school, State Board of Medical Examiners, or Medical Society, or who shall practice under cover of a medical diploma illegally obtained, and for the purpose of qualifying a person neither licensed nor possessing a diploma of the nature of that mentioned to practice medicine or surgery, it was provided that he should obtain a certificate from the censors of a medical society either in the county, district or State, in which it should be set forth that he had been found qualified to practice all the branches of the medical art mentioned in it. It appears to be quite manifest that the object of the Legislature in the enactment of this chapter was only for regulating the practice of medicine or surgery, as those terms are usually or generally understood, and confining them to such significance, it is evident that they would not include the occupation of the plaintiff. The practice of medicine is a pursuit very generally known and understood, and so also is that of surgery. The former includes the application and use of medicines and drugs for the purpose of curing, mitigating or alleviating bodily disease, while the functions of the latter are limited to manual operations usually performed by surgical instruments or appliances. It was entirely proper for the Legislature by means of this chapter to prescribe the qualifications of the person who might be intrusted with the performance of these very important duties. The health and safety of society could be maintained and protected in no other manner.

"To allow incompetent or unqualified persons to administer, or apply medical agents, or to perform surgical operations, would be highly dangerous to the health as well as the lives of the persons who might be operated upon, and there is reason to believe that lasting and serious injuries as well as the loss of life have been produced by the improper use of medical agents and surgical implements and appliances. It was the purpose and object of the Legislature by this act, to prevent a continuance of deleterious practices of this nature, and to confine the uses of medicine and the operations of surgery to a class of persons who, upon examination should be found competent and qualified to follow their professional pursuits. No such danger could possibly arise from the treatment to which the plaintiff's occupation was confined. While it might be no benefit, it could hardly be possible that it could result in harm or injury, and for that reason no necessity existed for interfering with this pursuit by any action on the part of the Legislature. His system of practice was rather that of nursing than of either medicine or surgery. No bodily disability or diseases could either result from or be aggravated by the applications made by him, and what he did in no just sense either constituted the practice of medicine or surgery. He neither gave or applied drugs or medicine, nor used surgical instruments."

It is my opinion that our statute is susceptible of the same construction expressed in said case of such license the sum of $1 50, and such Clerk shall record such license, together with the name of the college in which such applicant graduated, and the date of his or her diploma, in a book to be kept for such purpose, and which shall be a public record "

1 No particular school or system of medical practice is preferred by the law, and no rights are conferred upon one not accorded to all, and a practitioner in his treatment is to be tested by the general doctrines of his school, and not by those of other schools and systems of medicine

All recognized schools and systems of medicine stand equal before the law and equally reputable The statute does not require the medical college to be incorporated from which the certificate or diploma is derived (Holmes vs Holde, 74 Me, 28–38)

Every institution, whether incorporated or unincorporated, organized in good faith for scientific instruction in medicine, surgery or obstetrics, and in which such scientific instruction is systematically imparted, without regard to the school of medicine under whose control or management it is, is a reputable medical college within the meaning of the statute

The graduation in, and diploma from a college, referred to by said statute, are not limited to an institution within the State of Indiana, or the United States

2 Under the statute, when an applicant shall file with the Clerk his or her affidavit, stating that such applicant has regularly graduated in some reputable medical college, and shall exhibit to such Clerk the diploma held by such applicant, it becomes the duty of the Clerk to issue to such applicant a license to practice his profession This is the only condition prescribed by the statute, and the officer can not require more from such applicant

Q 2 —"Will the physician holding a certificate of membership of fifteen years standing in a Homœopathic Medical Society of another State, and has had ten years, though not continuous, practice in Indiana, be entitled to a license to practice medicine in Indiana?"

A certificate of membership in a medical society confers no rights under the statute The statute requires the Clerk to issue a license to three classes of physicians

1 Where the physician has graduated in some reputable medical college, and has received a diploma

2 Where he has resided and practiced medicine, surgery and obstetrics in this State continuously for ten years immediately preceding the date of the taking effect of the statute

3 Where he has resided and practiced medicine, surgery and obstetrics in this State continuously for three years immediately preceding the date of the taking effect of this act, and has attended one full course of lectures in some reputable medical college The letter of the statute requires the applicant to have resided and practiced medicine, surgery and obstetrics in this State continuously for ten years A similar statute has been sustained and held to be constitutional

The letter of our statute also requires the applicant to have practiced medicine, surgery and obstetrics in this State continuously for ten years, immediately preceding the date of the taking effect of the statute In Wert vs Clutter (37 Ohio St, 347) it was held that such ten years of continuous practice may embrace time since as well as before the taking effect of the statute, but the statute in Ohio is unlike our statute on this subject

In ex parte Spinney (10 Nev, *323*) Beatty, J, held "that there is some reason for requiring ten year's practice in this State as a qualification for the continued practice of medicine and surgery, but there is no sort of reason for requiring that practice to have extended over the particular ten year's 'immediately preceding the enactment of the law,' and to this extent the law is unconstitutional To so decide, however, would leave a good and perfect statute, omitting only the words 'next preceding the passage of this act'" In this latter proposition there was no concurrence by the other Judges, but Hawley, C J, held said clause to be constitutional, and it is proper to follow the letter of the statute, which declares that the applicant must have resided and practiced medicine, surgery and obstetrics in this State continuously for ten years, immediately preceding the date of the taking effect of the statute, before a license may be issued The term "continuous practice," in the sense of the statute, does not mean constant practice, never ceasing

It is not necessary that a physician should have a patient each day during the ten years immediately preceding the operation of the statute to have been in continuous practice and to obtain a license

No criterion can be established on the basis of the quantity of business enjoyed by a physician to determine whether he has or not continuously practiced his profession for said time

If for said time the practice of medicine, surgery and obstetrics has been his profession and business, and he has not wholly abandoned it for another occupation, and he has practiced his profession as often as he has had requests and occasion to do so, I think he may be deemed to have continuously practiced medicine, surgery and obstetrics for ten years immediately preceding the operation of the statute, and is entitled to a license

Q 3 —"Is a certificate of membership from either State Medical Society of this State sufficient to entitle the holder to a license to practice medicine in the State, provided the holder has never attended a medical school, and has not been in continuous practice in the State for ten years previous to the taking effect of the medical act?"

A —No

Q 4 —"Does the statute apply to a person who undertakes to cure diseases by manipulating the patient's body, by rubbing, kneading and pressure?"

A —The statute applies to persons desiring to practice medicine, surgery and obstetrics only, and it ought not to be so construed as to cover persons not substantially within its terms

In Wert vs Clutter, supra, the Court says 'This statute was not intended to create a right in anyone to practice medicine It was simply intended to prohibit the exercise of the right (which before was universal) by unqualified persons. The right remains in all persons, except those from whom it is taken away by the statute."

In Bibber vs. Simpson (59 Me., 181) suit was instituted for $51 for services rendered the defendant's intestate, at his special request, by the plaintiff as a clairvoyant.

It appeared from the plaintiff's testimony that she professed to be a clairvoyant, that when asked to examine the patient she saw the disease and felt as the patient did, that sittings or seances were of different durations from one quarter to one half of an hour each, that she did not pretend to understand medicine or anatomy, that she was requested by the intestate to visit him and render him professional services, and did so as by the account, that she helped him, but he died from taking cold, acquainted him with the prices, and he agreed to pay them, but never did.

Appleton, C. J., in deciding the case, says: "The services rendered are medical in their character. True, the plaintiff does not call herself a physician, but she visits her sick patients, examines their condition, determines the nature of the disease and prescribes the remedies deemed by her most appropriate. Whether the plaintiff calls herself a medical clairvoyant, or a clairvoyant physician, or a clear seeing physician, matters little, assuredly, such services as the plaintiff claims to have rendered, purport to be, and are to be deemed, medical, and are within the clear and obvious meaning of R. S., 1871, c. 13, Sec. 3, which provides that 'no person, except a physician or surgeon, who commenced prior to Feb. 16, 1831, or has received a medical degree at a public medical institution in the United States, or a license from the Maine Medical Association, shall recover any compensation for medical or surgical services, unless previous to such services he had obtained a certificate of good moral character from the municipal officers of the town where he then resided.' The plaintiff has not brought herself within the provisions of this section, and cannot maintain this action."

In Smith vs. Lane (24 Hun., 632), Daniels, J., says: "The action was brought to recover the price which it was alleged the defendant agreed to pay the plaintiff for the treatment of himself and wife for certain bodily disabilities. It consisted entirely of manipulations with the hands. It was performed by rubbing, kneading and pressure. The evidence given by the plaintiff was to the effect that he was employed by the defendant to perform these services for a specific compensation, and that he had performed them until the amount due him was the sum of $149. Upon the close of the case on his part, the referee dismissed the complaint because it appeared that the plaintiff was not a graduate of any medical school, and had no license permitting him to practice either medicine or surgery. The direction was given because of the prohibition contained in Chapter 436 of the laws of 1874, and, as no other reason appeared in the case, or the evidence which was given that would prevent the plaintiff from recovering, and whether this act contains anything subjecting him to such disability, is the only substantial point which requires to be considered in the case. The statute in terms merely declared it to be a misdemeanor for any person to practice medicine or surgery who is not authorized to do so by a license or diploma from some chartered school, State Board of Medical Examiners, or Medical Society, or who shall practice under cover of a medical diploma illegally obtained, and for the purpose of qualifying a person neither licensed nor possessing a diploma of the nature of that mentioned to practice medicine or surgery, it was provided that he should obtain a certificate from the censors of a medical society either in the county, district or State, in which it should be set forth that he had been found qualified to practice all the branches of the medical art mentioned in it. It appears to be quite manifest that the object of the Legislature in the enactment of this chapter was only for regulating the practice of medicine or surgery, as those terms are usually or generally understood, and confining them to such significance, it is evident that they would not include the occupation of the plaintiff. The practice of medicine is a pursuit very generally known and understood, and so also is that of surgery. The former includes the application and use of medicines and drugs for the purpose of curing, mitigating or alleviating bodily disease, while the functions of the latter are limited to manual operations usually performed by surgical instruments or appliances. It was entirely proper for the Legislature by means of this chapter to prescribe the qualifications of the person who might be intrusted with the performance of these very important duties. The health and safety of society could be maintained and protected in no other manner.

"To allow incompetent or unqualified persons to administer, or apply medical agents, or to perform surgical operations, would be highly dangerous to the health as well as the lives of the persons who might be operated upon and there is reason to believe that lasting and serious injuries as well as the loss of life have been produced by the improper use of medical agents and surgical implements and appliances. It was the purpose and object of the Legislature by this act, to prevent a continuance of deleterious practices of this nature, and to confine the uses of medicine and the operations of surgery to a class of persons who, upon examination should be found competent and qualified to follow their professional pursuits. No such danger could possibly arise from the treatment to which the plaintiff's occupation was confined. While it might be no benefit, it could hardly be possible that it could result in harm or injury, and for that reason no necessity existed for interfering with this pursuit by any action on the part of the Legislature. His system of practice was rather that of nursing than of either medicine or surgery. No bodily disability or diseases could either result from or be aggravated by the applications made by him, and what he did in no just sense either constituted the practice of medicine or surgery. He neither gave or applied drugs or medicine, nor used surgical instruments."

It is my opinion that our statute is susceptible of the same construction expressed in said case of

mentions "occupation for the mind of a comforting character, if possible, and cultivation of a religious conviction of the sanctity of life and the sin of self-inflicted death"

A few days ago, Dr Germain Seé read a paper on the treatment of obesity The method which he adopted for getting rid of superfluous flesh is simple, and does not involve so severe a regimen as that prescribed by the late Mr Banting Azotized food is, the doctor holds, the great cause of fat, and accordingly he insists on a sparing consumption of meat Alcoholic beverages he proscribes altogether, but he allows the victims of corpulency as much tea as they can drink This is the entire programme, and the professor is confident that it suffices

DOMESTIC CORRESPONDENCE

ARTIFICIAL ANÆSTHESIA

To the Editor of the Journal

Dear Sir—I am very much surprised to see the statement made by your London correspondent pass into your Journal without comment in regard to the discovery of anæsthesia He states as follows "Dr Simpson has the reputation of having been the discoverer of anæsthesia like Dr Harvey, they were really the men who brought the discoveries practically into use, and pointed out to us clearly and truthfully the *modus operandi* of the circulation and anæsthesia[1]"

The following are the facts in the case as to the "Discovery of the Art of Artificial Anæsthesia"

ANÆSTHETICS OF THE ANCIENTS[2]

"The ancient Greeks, it is stated, possessed a plant called mandrake It belonged to the same family of plants as the belladonna, or deadly nightshade From the root of this plant was extracted, by means of wine, a narcotic which was employed by them as an anæsthetic Lucius Apuleius, who lived about 160 A D, and of whose works eleven editions were republished in the fourteenth and fifteenth centuries, says, 'that if a man has to have a limb mutilated, sawn, or burnt, he may take half an ounce of mandragora wine, and whilst he sleeps the member may be cut off without pain or sense' Another fact was noticed by the ancients, that many volatile substances acted more promptly by inhalation than by the stomach, and this form of medication was employed in Greece, Rome, and Arabia By their published works, the knowledge of these facts was extended to other parts of the world

"In China, in ancient times, the word *ma yo* meant not only Indian hemp, but anæsthetic medicine, other substances besides hemp entered into these benumbing recipes, such as the datura, a solanaceous plant, probably identical with the atropia mandragora, also aconite, hyoscyamus, etc Some of these drugs form constituents of the formula said to be employed by kidnappers of children, and robbers, and are therefore naturally forbidden in China, at the present time, to be sold or employed

"The Indian hemp, under the name *bhang*, was extensively used by the Mohammedans and others in Central Asia The most wonderful properties are ascribed to it 'Taken in excess, the spirits and demons may be seen, it confers prophetic powers, it is sometimes taken by persons wishing to indulge in spiritualism, and it is used as an antidote to forgetfulness' (Dudgeon)

"A strong impulse was given to the study and application of the 'different kinds of airs and gases' by the discovery of oxygen by Priestley and Scheele, in the middle of the last century, and numerous experiments were made by physicians with it Another still more practical result was obtained by Sir Humphrey Davy, and published in 1800 'That nitrous oxide appears capable of destroying physical pain, and may be used with advantage during surgical operations' This valuable and practical suggestion remained without fruit for a long time, and the surgeons, physicians, and accoucheurs still employed alcohol, in some form, or opium and its salts, to deaden as far as possible the sensibility to pain during their various operations It was not until 1844 that an effort was made in the United States to make Davy's discovery useful, by Dr Wells, a dentist of Hartford, Connecticut, U S, who made, December 11th, 1844, the first application of the nitrous oxide gas to relieve the pain of the extraction of a tooth But the crowning result was obtained in 1846 by Dr Morton in the Massachusetts General Hospital, where it was demonstrated successfully that the inhalation of 'ether' was capable of so deadening the sensibility of the nervous system, that any operation, no matter how painful, could be performed, and the patient not suffer from its effects It was also proven that ether was a safe anæsthetic if in a proper case, and dose was administered by a competent individual, this was done first by the late Dr John C Warren,[1] of Boston, through whom it was introduced to the profession It was not until 1847 that Dr Simpson discovered chloroform to be a substitute for ether"

The whole world owe the United States a debt of gratitude for the introduction and practical application of the two safest and most effectual anæsthetics, nitrous oxide, and ether American men of science have done more than all others in the discovery and employment of anæsthetics, and should therefore receive the credit due to them

LETTER FROM LONDON

(FROM OUR OWN CORRESPONDENT)

Port-wine in Gout—National Sanitary Congress—The Effects of Lightning—See's Treatment of Obesity

Certain classes of sufferers will derive comfort from the teachings of Dr Peter Hood and Dr Morton Granville They are alike in recommending the use of port-wine matured in the wood, as a customary stimulant between the attacks of gout Dr Hood says " Notwithstanding its bad reputation as a cause of gout, there is no more wholesome wine than genuine port, when it is well matured, and the chief fault which can be imputed to it is that of palatability, which renders people disposed to partake of it too liberally The wine merchant will allege that long keeping in wood will deprive the wine of two of its most valued qualities, color and flavor This may be disputed, but it does not admit of doubt that wines so treated are far more wholesome than those which are bottled earlier Two or three glasses daily of such wine will act as a grateful stimulant to the stomach, and will assist digestion, but a larger quantity will produce defective assimilation, and those who so exceed must not be surprised if they become victims of gout

Dr Mortimer Granville says, in his 'Gout in its Clinical Aspects " Stimulants are almost always, I believe, necessary in cases of a gouty tendency, and during the intervals of the attacks I impose no restriction except that all alcoholic beverages shall be taken with food, and that new or imperfectly fermented wines shall be avoided Port which has been long enough in the wood to be thoroughly matured before bottling I regard as not only permissible, but to be recommended, particularly in the cases of those who are subjected to much mental worry It may be gathered from other paragraphs that the two authors also concur in the belief that the real or supposed injuriousness of alcoholic liquids in gout is not to be ascribed to the alcohol which they contain, but rather to some products of imperfect or incomplete fermentation, and it is good to be able to place on record their protest against the recommendation of "intemperate abstinence" which has of late years found favor with certain classes of practitioners and patients

In another work on Gout by Dr Robson Roose, the volume has its *raison d'être* in a desire to emphasize the degree in which gout is dependent upon derangement of the liver, to which other symptoms are but secondary In this view both the preceding writers are in accord with him, even if they do not give so much prominence to the doctrine, and it may be said, generally speaking, that the tendency of modern medicine is towards a close study of the functions and derangements of this most important organ, which a few years ago had been somewhat dethroned from the position in medical estimation which it held in the days of Abernethy and his school, and was neglected for a more accurate study of the action of nerve influences in the production of disease There is always a risk when one class of considerations is brought into prominence by the progress of scientific discovery, that others of equal significance may for a time be left out of account

The National Sanitary Congress has had a successful meeting at Leicester, under the presidency of Professor de Chaumont, who delivered the inaugural address Referring to the progress of sanitary science, he instanced the increased and increasing healthiness of British troops Thirty years ago, the death rate in the army at home was eighteen per 1,000, while the returns of 1883 showed that it had diminished to six per 1,000 In India and the West Indies the decrease was still more marked With regard to the duration of life, he said that the average of the metropolis was about forty one, including such extremes as St George's in-the East, in which over crowded parish it was only twenty-eight, and Hampstead, where it was fifty-six In conclusion, the President referred to vaccination, calling it one of the greatest boons ever conferred on humanity A discussion took place as to the relative merits of isolation as opposed to vaccination for the prevention of small pox, in which the Leicester speakers strongly upheld the former

Dr Liman has recently made some interesting observations on the effects of lightning exhibited in the bodies of two men who were struck down while taking shelter from a storm beneath trees The hair was singed, and the skin in many places discolored On one of the bodies was seen one of those peculiar figures which have often been described as impressions of branches, twigs, etc , and which have given rise to the fiction that the body of a person struck by lightning will sometimes bear a kind of photographic picture of the trees, etc , near him In this case the figure resembled a palm leaf, but it was traced to the contact of the folds of the shirt, such parts as were under pressure remaining white, the rest being discolored brown In the case of both men, some of the internal organs were ruptured

Mr Wynn Westcott, M B , London, the Deputy Coroner for Central Middlesex, has written a book on "Suicide," in which he deals with its history, literature, jurisprudence, causation and prevention It would seem that nowadays, at least, the number of suicides in all great towns vastly exceeds that of those in the country Moreover, single persons are more susceptible to suicidal mania than married, while widowed people of either sex are singularly apt to seek relief from their sorrows in death Climate and race, too, affect singularly the statistics which Mr Wynn Westcott has been at the pains to collect As remedies against the self destructive tendency, he mentions "occupation for the mind of a comforting character, if possible, and cultivation of a religious conviction of the sanctity of life and the sin of self inflicted death "

A few days ago, Dr Germain Seé read a paper on the treatment of obesity The method which he adopted for getting rid of superfluous flesh is simple, and does not involve so severe a regimen as that prescribed by the late Mr Banting Azotized food is, the doctor holds, the great cause of fat, and accordingly he insists on a sparing consumption of meat Alcoholic beverages he proscribes altogether, but he allows the victims of corpulency as much tea as they can drink This is the entire programme, and the professor is confident that it suffices

TUBELESS TRACHEOTOMY

To the Editor of the Journal

Dear Sir —During the past few years, at the meeting of the various medical societies, I have heard my friend, Dr Byrd, make the statement that the method of treating a case of tracheotomy without a tube, or what has been called *tubeless tracheotomy*, was originated by Dr Henry A Martin, of Boston, and he repeats the statement in his remarks on "Tetanus," in the JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, of October 10, 1885, page 400

---

[1] Journal American Medical Association Oct 24 1885

[2] Dr L Turnbull s Introduction to his first edition of his Manual of Anæsthesia March 1878

[1] The Advantages and Accidents of Artificial Anæsthesia by Laurence Turnbull M D Philadelphia 1878 p 208

[2] Surgical observations with cases made by I Mason Warren M D page 614

Now conceding all that Dr Byrd says of Dr Martin as a distinguished surgeon, he did not originate, introduce, or suggest this method of tracheotomy, and I cannot think that Dr Martin ever claimed it Dr Daniel Brainard was the surgeon who first made known and advocated this method, and it should be known as Brainard's operation for tracheotomy In the *American Journal of the Medical Sciences*, vol xxxviii, page 291, in an article entitled "Suggestions of Improvements in Tracheotomy, by Daniel Brainard, M D, of Chicago," will be found a complete description of this method, and in the *Chicago Medical Journal*, for 1859, page 134, after reporting a case operated on in this way, he goes on to say

"The suggestions which I have to offer in regard to tracheotomy, relate to the means of preventing hæmorrhage, to keeping the opening made by the operation pervious without resorting to a tube, and at the same time controlling the entrance of cold air abruptly into the lungs In order to prevent hæmorrhage I proceed in the following manner Having incised the skin and fascia by successive and careful incisions, I press the sterno hyoid, and sterno thyroid muscles to each side with the fingers, and thus expose the thyroid body This effected, I pass under the isthmus a director curved, or an aneurismal needle This is followed by a common suture needle, which may be passed with the blunt end foremost, armed with two very strong ligatures A ligature is then tied very firmly on each side, and the isthmus of the thyroid body divided between them A little dissection with a blunt instrument denudes the trachea to the required extent, and an opening can be made without danger of a drop of blood being drawn into it

"The ligatures which have been thus secured, serve the purpose of fixing the trachea, if desirable, and they may be tied behind the neck so as to raise it forward, and keep the wound open I never open the trachea until the hæmorrhage is stopped, and a large surface of it has been quite denuded" 2 '*Keeping the opening in the trachea pervious without resorting to a tube*'—The objections to a tube are twofold 1st, When the operation is performed for the extraction of a foreign body, it prevents its exit, and it is desirable to leave this opening in such a state that the foreign substance may escape whenever it becomes loosened from its situation in the bronchia 2d, In tracheotomy for croup, the prolonged sojourn of the tube has been considered, by the most eminent surgeons, as a cause of the pneumonias, which so frequently are the cause of death

"The necessity for using the tube I avoid by the following means Having denuded the trachea, insert a small suture needle, armed with a ligature, beneath two of its rings Withdraw the needle, and drawing gently upon the thread, make a semi circular incision on one side, so as to form a valve, readily opened by drawing upon the thread The opening thus formed can be kept patent, or be allowed to close at will"

It will thus be seen that what Dr Byrd claims for Dr Martin should be credited to Dr Brainard—a man who posessed a powerful and commanding intellect, who was a great and original genius in surgery, and who made many improvements and suggestions for the advancement of his favorite branch Prof Gross expressed his estimate of the man when he said "There are three great surgeons now living, and of the three Brainard is not the least"

Just now we frequently read in extracts from foreign journals about Martin's method of treating spina bifida with iodine injections, a plan originated and successfully used by Brainard thirty-five years ago, and the work of the Western surgeon is entirely ignored *Honor to whom honor is due*

BOOK REVIEWS

1 SITZUNGSBERICHTE DER PHYSIKALISCH-MEDICINISCHEN GESELLSCHAFT ZU WURZBURG 8vo, pp 164 Jahrgang, 1884

2 VERHANDLUNGEN DER PHYSIKALISCH-MEDICINISCHEN GESELLSCHAFT ZU WURTZBURG Herausgegeben von der Redactions-Commission der Gesellschaft, DR JOHANNES GAD, PROF DR W REUBOLD, DR KONRAD RIEGER Neue Folge, XVIII Band 8vo, pp 321 Wurtzburg

PROCEEDINGS OF THE PHYSICO-MEDICAL SOCIETY OF WURTZBURG Wurtzburg Stabel's University Press

We feel somewhat disposed to quarrel with the Publication Committee of the Wurtzburg Society for delaying the publication of these proceedings of 1884 until the middle of the present year Some of the papers and discussions are quite valuable, and all are more or less interesting, and there seems to be no good reason why they—the medical papers, at least—should not have been before the profession some time ago

1 The first paper in this volume is an interesting contribution to the subject of "Contortionists," by Hans Virchow And why the author should have gone out of his way to use such a word as *Schlangenmenschen* for *Contortionists* passes all understanding, especially as two highly educated Germans declared, on seeing the title, that it meant "Snake charmers" Be this as it may, the paper is an interesting contribution to the anatomy of contortionists

Dr H Maas contributes three papers to this volume, the first concerning *Plastic Operations in the Treatment of Ulcers*, pediculated flaps being turned from the adjacent sound parts, but a piece of healthy skin is left between the ulcer and the place whence the flap is taken, a method which, on histological grounds, is recommended by Kolliker His second paper is on the *Operations for the Cure of Ulcers of the Heel* After mentioning the operations recommended and performed by Mickulicz, Billroth and Czerny, the last two being by using granulating skin flaps, he refers to the operation recommended years ago by Wutzer and Scymanovsky—extirpation of the ulcer and transplantation of pediculated flaps He then reports an interesting case operated upon in this manner The third paper is the report of a remarkable case of *Lymphangioma* (with exhibition of patient) The patient was three years old, with an undescribed combination of lymphangiomatous tumors, with vascular angiomata of the skin On the patient's neck was a cystic lymphangioma, on the lower lip was a capillary tumor with perhaps cavernous dilated lymph-vessels, and in the right parotid region was a cavernous lymphangioma

Von Kolliker also contributes three articles, on the "Non-Existence of Embryonal Connective tissue Cells," the "Anatomy of the Clitoris," and on "Twin formation in Mammals" Ph Stohr has an article on "The Tonsils in Pyopneumothorax," and "Mucous Glands," which are chiefly of pathological interest Kirchner also has two papers, on "Cholesteatoma of the Temporal Bone," and "The Relation of Aural to General Diseases" J Gad has a short paper on the "Paths of Transmission and Centres in the Spinal Cord of the Frog" Rindfleish has a paper on the "Differential Diagnosis of Diphtheritic Tonsillitis," Rosenberger one on "Incarceration and the Radical Operation of Large Herniæ," and Rieger a long article on "Progressive Paralysis"

2 The second volume opens with a paper on the "Diagnostic Value of the Tubercle Bacillus," by Friedrich Muller, which contains nothing that could now be considered new C Fr W Krukenberg has a long article on "Hyaline," a chemico physiological study from the Wurtzburg Institute He also has an article on "Some Important Color-Reactions" Of great interest is A Kolliker's address at the opening of the new Anatomical Institute in Wurtzburg in 1883 Dr A Hausmann, formerly of St Louis, contributes some "Observations on Yellow Fever" Gad has a very long and interesting study on the same subject as in the paper in the first volume considered A Fick concludes the volume with a discussion of "Myothermic Questions and Experiments"

ASSOCIATION ITEMS

HONOR PRIZES

REPORT OF THE COMMITTEE

At the last meeting of the American Medical Association, in order to stimulate original research, a resolution was adopted offering *First and Second Honor Prizes* in each of the Sections for original papers in the same And in pursuance of a resolution, instructing the President of the Association to appoint a Committee of three, who should report subsequently through the JOURNAL, and "whose duty shall be to devise a system for the awarding of honors to those who may desire to present papers for prizes of honor in the different Sections at the next meeting of this Association," your Committee beg leave to report the following rules

1st No paper shall exceed thirty minutes in length

2d All papers must be sent sealed to the Secretaries of the Sections to which they belong, under a *nom de plume*, with the real name and accompanying *nom de-plume* sealed in envelopes and inclosed with the essays together with the real names and the *nom de-plume* of the papers to which they belong

3d There shall be three judges appointed in each Section on the afternoon of the first day one by the Chairman, one by the Secretary of the Section, and a third by the Section at large, who shall examine the papers, and decide on their merits, after which they shall return them to the Secretary, with the papers securing "first" and "second honor" so marked, and signed, by the judges concurring in that opinion, after which the Secretary shall open the corresponding envelopes in the presence of the judges, and announce the names of the authors securing the honors, who shall read their essays to the Sections to which they belong, as regular productions

If deemed worthy by the judges, all such other papers as are deemed meritorious by the judges, may be read before the Sections to which they belong, by their respective authors, who may obtain them at the hands of the Secretaries to whom they were first delivered

4th All papers competing for honors shall be in the hands of the Secretaries of the Sections to which they belong at least one week previous to the meeting of the Association at which they are to be presented

5th The judges are authorized to refuse honors to all papers deemed unworthy

6th No persons except members of the regular profession, will be deemed eligible to compete for honors

7th In the absence of their authors, papers receiving honors may be read by the Secretaries of the Sections in which they are presented

JOHN MORRIS, Baltimore, Md ,
Committee

NINTH INTERNATIONAL MEDICAL CONGRESS, WASHINGTON, D C , 1887

[The following are some of the more important Rules adopted relating to the preliminary organization of the Congress —ED]

1 The Congress shall consist of members of the regular profession of medicine, who shall have inscribed their names on the register and shall have taken out their tickets of admission, and of such other scientific men as the Executive Committee of the Congress may see fit to admit

2 The dues for members of the Congress shall be ten dollars each for members residing in the United States

There shall be no dues for members residing in foreign countries

Each member of the Congress shall be entitled to receive a copy of the "Transactions" for 1887

3 The Congress shall be divided as follows, into seventeen Sections

I General Medicine
II General Surgery
III Military and Naval Surgery
IV Obstetrics
V Gynæcology
VI Therapeutics and Materia Medica
VII Anatomy
VIII Physiology
IX Pathology
X Diseases of Children
XI Ophthalmology
XII Otology and Laryngology
XIII Dermatology and Syphilis
XIV Public and International Hygiene
XV Collective Investigation, Nomenclature, Vital Statistics, and Climatology
XVI Psychological Medicine and Diseases of the Nervous System
XVII Dental and Oral Surgery

4 The General Meetings of the Congress shall be for the transaction of business and for addresses and communications of general scientific interest

* * * * * * *

8 The official languages of the Congress shall be English, French, and German

In the meetings of the Sections, no member shall be allowed to speak for more than ten minutes, with the exceptions of the readers of papers and those who introduce subjects for discussion, who may each occupy twenty minutes

9 The rules and programmes shall be published in English, French, and German

Each paper and address shall be printed in the "Transactions" in the language in which it was presented, and preliminary abstracts of papers and addresses also shall be printed, each in the language in which it is to be delivered

All discussions shall be printed in English

10 The President of the Congress, the Secretary-General, the Treasurer, the Chairman of the Finance Committee, and the Presidents of the Sections, shall together constitute an Executive Committee of the Congress, which Committee shall direct the business of the Congress, shall authorize all expenditures for the immediate purposes of the Congress, shall supervise and audit the accounts of the Treasurer, and shall fill all vacancies in the offices of the Congress and of the Sections This Committee shall have power to add to its membership, but the total number of members shall not exceed thirty A number equal to one-third of the members of the Committee shall constitute a quorum for the transaction of business

11 The Officers of the Congress shall be a President, Vice-Presidents, a Secretary-General, four Associate Secretaries, one of whom shall be the French Secretary, and one of whom shall be the German Secretary, a Treasurer, and the Chairman of the Finance Committee

12 The officers of each Section shall be a President, Vice-Presidents, Secretaries, and a Council

13 The officers of the Congress and the officers of the Sections shall be nominated to the Congress at the opening of its first session

SUGGESTIONS IN REGARD TO THE CAUSATION AND TREATMENT OF ACUTE CORYZA[1]

BY AUSTIN FLINT, Sr, M D, LL D,

OF NEW YORK

Acute coryza may be produced traumatically by the inhalation of irritating gases Owing to a peculiar susceptibility, which with some persons is an idiosyncracy, the powder of certain substances, especially epicacuanha, produces the affection This is probably the explanation of the coryza which occurs in cases of so called hay asthma or hay fever The affection is an element in certain infectious diseases, especially rubeola, or measles Iodine, taken internally, in some persons produces this affection I do not purpose in this paper to consider the affection as occurring in the etiological and pathological connections just named, but as constituting what is commonly known as a "cold in the head," and the incipient stage of the epidemic disease known as influenza

When a person is said to "have taken cold," usually, as every one knows, the nostrils are first affected The affection may go no further, but in most instances it advances downward, sometimes affecting and sometimes passing over the pharynx and larynx, and ending in a bronchial inflammation The affection then may precede a "cold in the throat," a "cold in the windpipe," and a "cold in the chest" It is unnecessary to say that the proper medical names for these successive affections are rhinitis, pharyngitis, laryngitis, and bronchitis I need not also say that the term catarrh is often used in connection with the names of the several parts affected This term *Catarrh*, denoting an antiquated error, should long since have been excluded from medical nomenclature, and it is much to be regretted that the term has been adopted in the revised nomenclature recently published in London The name "cold," popularly used to denote coryza and the affections which follow it, implies that they are attributable to atmospheric influences of which the temperature is the factor They are especially attributed to the action of a current of air on the body when it is heated It is under these circumstances that a person is said to "take cold," and we all know how alive most people are to danger in this regard With many, one of the chief practical duties of life is to avoid "taking cold" Now I shall assume in this paper that coryza, when it occurs under circumstances implied by the name "cold in the head," is not the effect of an agency connected with the temperature of the atmosphere That the cause is atmospheric I admit, but the cause is of a special nature, and it is a reasonable supposition that the causative agent is a micro organism, in other words, the affection is parasitic The reasonableness of this view of the causation of coryza, is the first of the etiological suggestions which I propose to consider The question is, what are the grounds for the supposition that acute coryza is produced by a parasitic organism?

The notion that the affection which goes by the name "cold" is caused by cold, has very little to rest upon except its prevalence in and out of the medical profession It is a traditional notion nearly as fanciful as that expressed by the term catarrh, namely, that it is characterized by a secretion which flows down out of the brain Among those exposed by their occupations to violent alternations of heat and cold, coryza is not a frequent affection Long-continued exposure to cold, as in case of shipwreck, sleeping on the ground in a state of intoxication, etc, does not give rise to coryza. It is true that patients with this affection often refer it to some exposure, but this is because they suppose, as a matter of course, they must have "taken cold," and they accordingly fix upon a particular circumstance when and from which, they suppose the cold was taken In a large proportion of cases, however, the affection cannot be referred to any exposure, and it is not uncommon for patients to say that they cannot understand in what way they have "taken cold" Experience thus furnishes very little support for the notion that "a cold" is produced by cold

As is well known, coryza prevails to a greater or less extent at certain times and places, although the number of cases is not sufficient to constitute an epidemic prevalence How often is it remarked that "colds" are frequent, when they are not considered as cases of influenza This fact is evidence of the presence in the atmosphere of some special causative agent Such an agent, it is certain, is in the atmosphere whenever influenza prevails, and the coryza in influenza differs from that in ordinary "colds" only in that the nasal irritation or inflammation is usually more intense Now, if the coryza in influenza is due to a special atmospheric agent, a fair conclusion is that the same holds true in ordinary "colds," especially when the latter prevails more or less although not sufficiently to constitute an epidemic prevalence The atmospherical causative agent of the coryza is not an acrid or irritating material at the outset It is evidence of this that the development of the affection does not directly follow a sense of local injury or any olfactory sensation The coryza in other words, cannot be said to be produced traumatically The development of the coryza, and of the local affections in the parts below which follow, is consistent with the supposition of the presence of organisms which grow and multiply, and are carried by the inspiratory current of air to the pharynx, larynx, and bronchial tubes A fact which favors this view is the successive occurrence of pharyngitis, laryngitis, and bronchitis after certain intervals of time, namely from twelve to twenty-four hours In these intervals the parasite is multiplying in the situations from which it is to emigrate and form new colonies Acute coryza, like other parasitic diseases, is self-limited It runs a certain course, ending when the successive generations die out This is the explanation if the correctness of the parasitic doctrine be assumed

---

[1] Read at the meeting of the Fifth District Branch of the New York State Medical Association, Brooklyn Sept 23 1885

I have thus stated some rational grounds for the supposition that the acute coryza in influenza, and the affection known as a "cold" is produced by a parasitic organism To establish this view of the etiology of the affection it must be demonstrated that a special organism is always present in the affected part, that this organism is not found in this part or in other parts of the body when coryza does not exist, that the organism is capable of being cultivated outside of the body, and that coryza may be produced by placing pure cultures within the nostrils of man or lower animals The suggestion which I have here to make, is, that some one of our competent and enterprising microscopists undertake to obtain this proof

The suggestions in regard to the treatment of acute coryza are based on the supposed correctness of the parasitic doctrine If this doctrine be true, the great object of treatment is the destruction of the parasite, and if this can be done, the invasion of the situations below may be prevented, the affection being thus arrested in the Schneiderian membrane I have assumed all along that the coryza is the initial event in cases of "cold" and of influenza This is true of the majority of cases, but, exceptionally, as is well known, the affection may begin at the pharynx, the larynx or with the bronchial tubes In these cases the parasite travels without stopping beyond the nostrils, obtaining lodgment and forming colonies in either one of the situations just named With reference to the treatment of acute coryza, I have consulted the works of four American authors, each work able and of recent date The authors are Cohen, Ingalls, Robinson and Bosworth Of these authors, the parasitic causation is referred to by one only, Cohen, and by this author only in connection with influenza He does not dwell upon parasitic treatment, and by the others, parasiticides, as such, are not referred to All mention topical remedies, administered as powders by insufflation, or by a spray or vapor, but they are mentioned as remedies either to sooth or to excite the inflamed membrane, or as having antiphlogistic effect All mention a local remedy in repute among the Germans, and known as Brand's or the Brand Hager remedy, consisting of carbolic acid, 80 grs alcohol, half an ounce, liquor ammoniæ, 80 minims, and distilled water 154 minims The liquid is poured upon a sponge placed within a paper cone, and the vapor inhaled through the nostrils It is intelligible that this remedy may act as a parasiticide, but its efficacy is not attributed to that action by the authors just named

The parasitic doctrine of the etiology of coryza is not new Our distinguished countryman Mitchell who, like Moses, was permitted to see from afar the promised land in which medicine is now beginning to discover rich treasures, attributed influenza to the presence of a cryptogamic plant Sir Henry Holland in 1839 argued in favor of the animalcular origin of influenza and other diseases Some later writers (Hueter, Biermer), have considered as probable the bacterial origin of this affection The doctrine, however, has up to the present time, received so little consideration, that topical treatment with a view to the destruction of germs and organisms, has been tried to a very limited extent The permanganate of potassium, and the salicylate of soda, in solution, have been used, but with what success I am unable to say To these remedies is to be added the vapor of turpentine I have been told by one not of the medical profession, that the insufflation of quinia and camphor combined and pulverised has proved a successful method of abortive treatment Helmholtz found in his own case, that the injection of a solution of quinia into the nostrils, arrested the so called fever In other cases this treatment has not proved successful The efficient cause of this affection, however, is organic, but not an organism I have no facts to offer derived from my own experimental observations, respecting the employment of parasiticides or germicides for arresting a "cold" or an attack of influenza The opportunities for such observations are readily available by medical practitioners, and I submit, as a concluding suggestion, that a trial be made of the different articles of the materia medica, which are destructive of germs and living organisms without injury to the mucous membrane Should an article be found which is effective, prior to the demonstration of the parasitic doctrine, the successful treatment, it is needless to say, would furnish strong rational grounds for the support of this doctrine

THE UTILITY OF DRY DRESSINGS[1]

BY THOMAS C SMITH, M D,

OF WASHINGTON, D C

For several years it has been my practice to apply absorbent powders to such cases as I had formerly treated with ointments and lotions, and the treatment has been so satisfactory that I deem it a professional duty to urge its adoption by the profession

The vesicular and pustular diseases of the skin in infants were the first in which I adopted the "dry" treatment. A number of cases of so called *eczema facialis* and *E. capitis* were met within a short time, some of which had become chronic, had resisted all treatment, the doctor had been changed many times. Some of which had been under my own treatment by ointments and had been taken out of my charge and treated by regular and irregular practitioners, only to return to me for a new trial, in some hygienic and dietary conditions were bad. At one time I thought a remedy, which was to be a specific, had been found in the white precipitate used as strong as a dram to the ounce, but this expectation was doomed to follow others. Pounds of zinc and lead ointments had been prescribed for these cases with the usual results—disappointment to the physician and dissatisfaction on the part of patients and their friends. Some other course must be adopted, or some other doctor would take the case. I now determined to try the "dry" dressings, and one illustrative case will suffice to demonstrate the utility of the treatment.

---

[1] Read before the Medical Society of the District of Columbia October 7th 1885

In a family which I attend, a child, at that time ten years old, had been under treatment since birth for general eczema, which was worse, however, on the face and hands. The child's life had been almost a burden to her from the actual suffering caused by the disease and the annoyances due to the criticisms of children, who, besides making disparaging remarks, refused to play with her for fear of becoming contaminated. She had been under the treatment of many of the best physicians in the city without being benefited. Finally the disease seemed to die of itself. A second child in the same family became affected in the same way, and the parents were apprehensive that this child's case was to be the counterpart of the other. The face was covered with large crusts, from beneath which serum and pus were continually escaping to excoriate the healthy skin. The scalp was likewise affected, causing the hair to be matted to such an extent as to demand its removal by the scissors in order to keep the child at all decent. The hands and knees, also, were covered with large sores. It is unnecessary to further describe these appearances, as they are familiar to you all. It is proper to say, however, that this child was intensely scrofulous, as was the other one. As before remarked, the first child had been thoroughly treated, and in addition to cod liver oil took large doses and quantities of that arrant pharmacopœial fraud, syrup of the iodide of iron. This patient was put upon Scott's emulsion of cod liver oil, and locally a powder composed of oxide of zinc, starch, and a small quantity of carbolic acid, was applied freely. No effort was made to remove the crusts by poultices or water. Of course the child was washed on the healthy skin, and thoroughly dried, but the powder was not touched.

This is a point which cannot be too strongly emphasized—not to use water after the treatment by the powder has been commenced. The formation of a crust I look upon as a conservative process, and endeavor by the drying powders to provide a substitute which does not present the repulsive appearance of a crust. If the crust is let alone, it will begin to break off at the edges, and if the dressing is promptly applied to the surface vacated by the crust, and this policy vigorously followed up, it is surprising how soon the diseased area is contracted, and a repulsive sore healed.

To return to the patient, and complete the history of the case by saying that speedy relief ensued from the treatment. This is but a single case, yet it is typical of twenty five or thirty which might be recited. Some may conclude that the results obtained were due to the constitutional treatment, but in so large a number of instances has local treatment been found sufficient that the first place must be given to the local applications. Still I generally give internal treatment in these cases, and now rely almost entirely on the sulphide of calcium for that purpose. Gelatine coated pills are usually prescribed, varying in strength from one-tenth to one half grain, of which one is to be given three times daily, dissolved in water. I find this the most eligible method of prescribing the remedy. Recently I have been using a prescription somewhat like this for the powder, which is to be applied in these and other cases which will be mentioned further on, viz.:

℞ Zinci oxid. ʒiv
Acid. tannic. ʒss
Acid. carbolic. cryst. gr. viii
Amyli pulv. ʒiiss. M.

Of course the ingredients are varied to suit individual cases, but my object is only to indicate a formula. Sometimes boracic acid is added, but bismuth is seldom used in my prescriptions.

A word as to the manner of using the dressing. When the face or head is affected, use warm water for cleansing purposes. Remove any loose crusts which have been detached, and with a dredging box, or any other suitable means, apply the powder thoroughly and thickly. It is not practicable to keep any cloths on the face to retain the powder, hence it must be applied oftener, but on the head a close-fitting cap may be used. On an extremity, the diseased surface may be covered to the depth of one-fourth of an inch with the powder, over which a piece of absorbent cotton may be placed and kept in contact by a bandage. In the latter situations it may not be necessary to disturb the dressings for several days, and on removing these it will usually be found that the discharges have been absorbed and that the powder is more or less lumpy. Some of this may be brushed away and more powder applied, but it is never necessary to try to get a view of the surface beneath the powder, as that will be seen in due time.

But it is not these cases alone which have been benefited by the "dry" treatment. Excoriations about the buttocks in children who are badly fed and nursed, and between the folds of the skin in fat babies during warm weather, when the discharge is excessive, yield to this treatment. The moist stage of eczema in adults has been relieved also. In fact almost any discharging surface will be relieved sooner by powders than by ointments or lotions.

Two other classes of cases remain to be mentioned for consideration, viz., suppurating wounds and ulcers While a number in each class have been benefited, one case in each will be cited to show the efficacy of the treatment

In March, 1885, I was called to attend a man whose hand had been caught in the machinery in a planing mill The proximal end of the second phalanx of the middle finger of the right hand had been broken obliquely off, the joint torn open and dislocated, and the broken piece of bone adhering to the integument was lying on the side of the finger With some difficulty the dislocation was reduced and the finger placed upon a splint to which it was bandaged, and then the whole hand placed on another splint The wound had been washed with carbolic solution, which was also applied to the finger on cotton before bandaging On the third day erysipelas supervened, making it necessary to remove the splint from the finger, and dislocation ensued despite my efforts to prevent it On the subsidence of the erysipelas the wound in the finger was found to be filled with granulations, and a large quantity of pus escaped from the parts Iodoform ointment was ordered, and the wound daily cleansed with carbolized water, but things went from bad to worse, and finally, I ordered the powder compounded according to the formula above given Improvement commenced at once, suppuration diminished, the patient's appetite improved and his condition was encouraging in every way, when he left the city about three weeks after the injury was inflicted Shortly afterwards I received a letter from his physician in Pennsylvania, asking for a copy of the prescription for the powder, which he stated had proven very useful in the case and he desired to continue it I do not know what the result of the case was, although I believed that amputation of the finger would be necessary, still the comfort afforded the patient by the dressing mentioned, and the marked improvement in the appearance of the wound before the case passed from my charge, justifies me in saying that it was the proper treatment

About four months ago I was asked to see a lady about 65 years of age, who had been a cripple for four years from ulcers affecting the lower part of the right leg and foot The ulcers were deep and painful, and were probably of varicose nature The back of the ankle, the side of the foot as far as the metatarsophalangal joint and the plantar surface of the heel were the seat of about eight or ten ulcers, from all of which pus flowed in considerable quantity The tendo-achillis was exposed in the bottom of one of these ulcers

The patient had been, for years, using zinc ointment, and as she expressed it, "without doing any good " I directed her to cleanse the parts thoroughly, and then dry them with absorbent cotton, after which she was to fill each ulcer with the powder and heap the same on the surrounding surface She was then to cover the parts with absorbent cotton so as to prevent the powder from falling away, and finally secure the whole with a bandage The dressings were not to be removed for two days unless they became uncomfortable Improvement began at once, and at this time all the ulcers have healed except one The patient is able to bear her weight on her foot and walk without pain, and is very grateful in her expressions for the relief which has been afforded

Still another class of cases which I omitted to speak of before, may be mentioned now I have reference to cases of sore nipples In several cases recently under my care, the patients have been relieved by the dry applications after the usual ointments had failed to afford relief

I am not aware of any systematic effort to introduce dry dressings in the treatment of cases, such as have been herein mentioned Hewson's "dry earth" treatment was a move in the right direction and deserved more consideration than it received In looking over the prescription files in drug-stores, I have been struck with the remarkable absence of prescriptions for dusting powders and the great numbers of orders for ointments This has forced me to believe that the utility of dry dressings is not appreciated by the profession as it should be, and for that reason it is now introduced for discussion

In conclusion I wish to present the following propositions, which it is believed are based on correct principles —Dry dressings of the character above indicated in the treatment of cases such as those referred to are rational, comfortable, cleanly, easily applied, antiseptic and efficacious

DISEASES OF THE ANTRUM HIGHMORIANUM, WITH REPORT OF TWO CASES[1]

BY G W HUDSON, M D,

OF CAMDEN ARK

It was not until the knowledge of anatomy had made considerable progress that the existence of this cavity was known Highmore, in the early part of the seventeenth century, was the first anatomist to give a correct description of this cavity I hope it will not be thought presumption in me to call attention briefly to the anatomical outlines of this cavity

It should be remembered, in connection with diseases of the maxillary sinuses, that this cavity is of considerable size, with walls of different thickness In youth the walls are thick and the cavity small After attaining its maximum size in the adult it is again diminished in old age It is larger in males than in females But in adult life its size varies in different subjects, and the larger the cavity the thinner the walls The roof is formed by the orbital plate, and the thickness of the floor by the alveolar process, the inner wall or base presents, in the disarticulated bone, a large irregular aperture, which communicates with the nasal fossa The margins of this aperture are thin and ragged, and consequently easily broken down in cachectic subjects with disease of the nasal cavity of a chronic, mercurial, or venereal nature

Owing to the close proximity of the floor of the sinus to the alveola, the roots of the molars, bicuspid and cuspid teeth frequently enter the cavity, and if all the circumstances connected with diseases of the antrum could be ascertained, the majority of them doubtless have their exciting causes in a diseased condition of the teeth, gums, or alveolar process

---

[1] Read before the State Medical Society of Arkansas April 22 1885

I have had several cases of disease of the antrum under my observation within the last two years, and with two or three exceptions, the exciting or premonitory cause was found in decayed teeth, or periodental abscesses The most simple way to find out whether the teeth are the offending cause is to tap each tooth sharply with an instrument, when, if there is one that is diseased at the root or enters a diseased antrum, the patient will cry out with pain There are other lesions of this cavity, caused by carelessness in extracting teeth, and by direct blows upon the face, or the patient may contract a violent cold, the excitement expends itself about the nerves, the Schneiderian membrane becomes inflamed, and by simple continuity of structure the lining membrane of the sinus becomes vascularly excited or congested to such an extent as to close the opening into the nerves The mucus thus confined will, if not removed, sooner or later become purulent, and make its exit through the most dependent points of the cavity, which generally proves to be either through the nasal septum or the alveolar cavities, burrowing along the fangs, escaping around the necks of the teeth, and occasionally through the cheek Cases are reported in which the orbital plate gave way and the pus found its exit somewhere along the lower eyelid The cavity is also subject to some of the most formidable and dangerous growths, both malignant and non malignant, that the physician or surgeon is ever called upon to treat

The symptoms of a diseased maxillary sinus are varied I have generally found the patient complaining of a heavy, dull sensation in the cheek, and at times of an acute lancinating pain, usually attended by some constitutional disturbance, high temperature and rigors I wish to insist upon the importance of an early diagnosis, as it may be safely assumed that in a large majority of the cases of disease of the antrum, the danger to be apprehended arises more from neglect than from any necessarily fatal character of the malady My experience warrants me in saying that the majority of the cases that have come under my care have been sadly neglected, and treated for everything but the real disease The rule (unless the case is well marked) is to give the patient some simple remedy for nasal catarrh—or his case is pronounced one of facial neuralgia, and some favorite panacea prescribed

The treatment of incipient disease of the antrum is generally very simple Success depends in these cases (as in all others) upon an early and proper diagnosis Remove the cause of offense, when possible, either by surgical procedure or judicious medication The following case will illustrate what I have been trying to explain,

Mr W , aged 58, merchant, had suffered a great deal from pains in his face and head He had been under treatment almost constantly for five years for facial neuralgia. His teeth had been defective for ten years, frequently has abscesses around the superior molars of the left side Gums swollen, a heavy, dull pain in the cheek under the eye, attended at times with fever and rigors Nasal cavity dry and hot Suspecting disease of the antrum, I advised the extraction of the decayed teeth, to which he reluctantly consented After extracting the teeth, upon examination, I found the alveolar processes spongy and bathed in pus, which went to confirm my diagnosis,—then, with a triangular pointed instrument, the floor of the antrum was perforated through the alveolar cavity of the first molar, the withdrawal of the instrument was followed by about half a teaspoonful of muco purulent fluid, showing conclusively that this cavity had been diseased for some time

The treatment consisted in syringing out the cavity twice a day with warm water and a wash composed of compound tincture of iodine and Listerine—each time closing the opening with a pledget of absorbent cotton This treatment was kept up about six weeks At the expiration of this time he reported himself perfectly well, and twelve months have now elapsed and he has had no return of his former trouble

Case 2 —Mr K , aged 48, teacher, has suffered more or less with pains in the face and head for ten years All of his teeth were extracted two years ago The pain was of a heavy, dull character, extending from below the left eye to the eye, temple and ear, simulating neuralgia to a marked extent For twelve months before he came under my charge, he had violent clonic contractions of the facial muscles of the left side, particularly of the masseter muscle, coming on every fifteen or twenty minutes and lasting eight or ten seconds—when the spasm came on he had to stop talking or eating, and catch his jaw and hold it until the paroxysm passed off He also complained of a tickling sensation in the throat, as though something was dripping from the soft palate There was no tumefaction of the gums or soft parts The palatal and maxillary bones were to all appearance in a healthy condition The muscles of the face were soft and somewhat relaxed when the paroxysms passed off No appearance of paralysis The lower eyelid a little everted, sight very good, hearing dull, tympanic membrane normal, though pale The speech was more thick than usual The mucous membrane of the pharynx and posterior nares was thickened and indurated

With this array of symptoms, I did not venture upon a diagnosis, and my prognosis was not favorable to a rapid recovery Suspecting, however, that a diseased condition of the antrum might be the exciting cause of some of the prominent symptoms, I advised trephining the sinus, to which he consented The operation was commenced by making a crucial incision through the gums over the alveolar process near the origin of the second molar, and after desecting back the flaps, the floor of the antrum was perforated with a triangular pointed instrument, and a quantity of muco purulent fluid escaped The subsequent treatment of the cavity consisted in using astringent and detergent washes

The muscular contraction was slow to yield Electricity, both galvanic and Faradaic, was used, but only aggravated the paroxysms A prescription of phosphide of zinc and strychnine seemed well suited to the case, and he improved rapidly on it At the expiration of about eight weeks he reported himself cured, and has no symptoms of his former trouble

In making my report of this second case, I shall leave you to draw your own inferences, for I must say that some of the symptoms were very obscure, and I have been unable to account for them

---

CHRONIC CONJUNCTIVITIS DEPENDENT UPON DISEASE OF THE INTRA-NASAL TISSUES[1]

BY N R GORDON, M D,

OF SPRINGFIELD ILLS

There is a form of conjunctival disease which is dependent upon chronic inflammation of the intra-nasal tissues I am not aware that any author has made special mention of this subject, but some have given a passing notice without particular effort to portray the condition of the nasal and ocular mucous membrane The intimate connection existing between the conjunctiva and the Schneiderean membrane through the medium of the vaso motor and sympathetic nerves, does not here require elucidation

Observation has taught that irritation affecting the ocular mucous membrane is reflected to the nasal mucous membrane, and *vice versa,* this action takes place through the intervention of the vaso motor nervous system This conjunctival disease is chronic inflammation of the conjunctiva and the connecting tissues, accompanied by increased thickness of the membrane, especially of the palpebral portion, which is very slightly roughened, giving it somewhat the appearance of trachoma in a mild form The tarsal cartilages, tarsal glands and ciliary follicles are more or less involved, with marked lachrymation and photophobia, pain is sometimes intermittent, more severe in afternoon These cases are very chronic in character, and possibly in the majority of instances have been cases of trachoma, which may be the legitimate offspring of conjunctival inflammation, the trachomatous growth has either been destroyed by treatment, or not appeared as a sequel or complication of the inflammatory action Usually the former condition exists

My experience does not enable me to give any reliable diagnostic symptom or condition which would aid in the discrimination between the idiopathic and sympathetic form of chronic conjunctivitis, that is, from the examination of the eye alone, but the diagnosis may be determined by the coexistence of disease of the intra-nasal tissues This disease of the intra nasal tissue is usually a chronic rhinitis, of the hypertrophic character—mucous membrane exquisitely sensitive, with an abundant flow of thin, watery mucus

The objective symptoms are those of acute rhinitis, with a chronic duration, or with the appearance as presented in so called hay fever A marked and important character of the conjunctivitis is its chronicity, it is not limited by weeks or months, but years, it yields slowly and only temporarily to the orthodox method of treatment of chronic conjunctivitis The patient contracts cold with great ease and frequency, followed by an increase in the already copious flow of mucus from the nasal passages, also an increase in the grade of inflammation of the conjunctiva, often muscular rheumatoid pains, especially in patients beyond middle life

The successful management of this form of conjunctivitis depends upon the proper treatment directed to the nasal passages Dr Noyes says that nasal catarrh often is causative of conjunctivitis, and when such is the case requires treatment Many cases of chronic conjunctivitis that visit the oculist for months to receive treatment for the eye alone, may be speedily cured by directing the treatment to the nasal and post-nasal surfaces, thus making the ophthalmic treatment secondary in importance, as will be developed in the report of cases Vaseline, in which there is incorporated a small amount of eucalyptol and pinus Canadensis, is sprayed in the nasal and post-nasal passages daily, until the parts give evidence of improvement, which is usually about two weeks, then less frequent until the patient recovers

The ophthalmic treatment consists in the application of plain vaseline, or in combination with boracic acid This application, which is made by the patient, should be very free and frequent, three or four times per day, with considerable friction Suitable systemic medication is prescribed according to the indications Under this treatment I have seen rapid recovery take place of the most severe forms of chronic conjunctivitis, as is shown in the following cases

Case 1 —Mrs M , aged 53 years, eyes affected for seventeen years During the last eighteen months of this time she states they were in the condition in which I found them at the time of her first visit to my office, Nov 25th, 1884 The conjunctiva was intensely red and injected, and somewhat roughened from hypertrophy of papilla, and epithelium, tarsal cartilages and tarsal glands, and ciliary follicles were involved, great lachrymation and photophobia, the diffused light from the window caused an increase in pain She was led by an assistant

The intra-nasal tissue was found to present the condition characterized by chronic rhinitis with hypertrophy of the turbinated processes, copious flow of watery mucus from the nasal cavities, and increased amount of sticky, tenacious mucus from the post-nasal surface The posterior wall of pharynx was ramified by enlarged tortuous blood-vessels, indicating the existence of chronic inflammation She was treated daily for three weeks, at which time she was considered well enough to return home About the middle of January, six weeks after the time she began treatment, she returned to my office, her eyes looking quite well, and but little indication of the former disease Thus within the space of six weeks she was cured, and her eyes remain well to the present time

Case 2 —Mrs G aged 50, eyes affected for twelve years At the time of her first visit to my office, June 24, 1884, her vision was $\frac{20}{cc}$, which condition she affirmed had existed for four or five years

Examination revealed practically the same condi tion as existed in Case 1, as regards the ocular and nasal mucous membrane, except a slight degree of pannus, which would account for the great loss in vision

---

[1] Read before the American Rhinological Association Lexington, Ky , October 1885

This patient was under treatment for two months, when she was dismissed as cured She recently informed me by letter that her eyes have remained well, that vision has improved, and she is now able to read ordinary print

The above cases were both treated, prior to my treatment, by eminent oculists, from nine to twelve months each, without perceptible improvement, one had spent a term at Eureka Springs, Ark Other cases could be reported, but it is unnecessary, these show, by the immediate and perfect recovery in each case, the efficacy and correctness of the treatment The conclusions, therefore, as the above cases had persistently resisted the usual method of treatment for like conditions, and the rapid and perfect recovery from the treatment as above described, is positive evidence of the correctness of the diagnosis and value of treatment

The local sedative treatment to the nasal mucous membrane relieved the irritation reflex of the conjunctiva, thus making recovery possible, which otherwise could not be, while the primary point of disease was disregarded

THE RATIONAL TREATMENT OF PULMONARY DISEASES BY THE PNEUMATIC CABINET

BY W EVERETT SMITH, M D (HARV)

FELLOW OF THE MASSACHUSETTS MEDICAL SOCIETY MEMBER OF THE AMERICAN MEDICAL ASSOCIATION FORMERLY ASST PHYSICIAN TO THE MASSACHUSETTS HOME FOR INTEMPERATE WOMEN

The use of the Pneumatic Cabinet[1] marks a new era in the treatment of lung diseases Until within about thirty years, pulmonary consumption was almost universally regarded as an incurable disease Indeed, it was only the occasional discovery of fibrous or cicatricial tissue and of calcareous masses in the lungs of patients who had died of other diseases, and in whose lungs there were no evidences of any recent inflammatory processes, that gradually led the medical world to believe that consumption could ever be cured Yet still the fact remained that the vast majority of patients with destructive lung diseases died The possibility of a cure being, however, conclusively established, the causes of these diseases began to be more carefully studied, with the hope of finally discovering some treatment directed to the removal of these causes

Many have been the methods advised—the internal administration of wood naphtha, cod liver oil, phosphate of lime, the hypophosphites, chlorate of potassa, benzoate of soda, various modes of counter-irritation, mercurialization, antimonial and other nauseating cough mixtures, vacuum cures, inhalations, etc , etc All may have their modicum of value, but all have failed to work the desired cure because they were not founded upon a physiological basis "It is a sound maxim in medicine," says Dr Austin Flint, "that the therapeutical indications derived from science and from nature, as a rule, should harmonize, and I will add that the true principles of therapeutics are in accordance with the dictates of common sense "

Adequately, to cope with disease, then, it is necessary thoroughly to understand the functions and requirements of health, and it is suggestive of the value of the treatment of lung diseases by the Pneumatic Cabinet that "its development is in line with and depends upon physiological axioms The life of lung tissue depends upon pure air, any interruption or irregularity in this supply means lung disease Whenever, then, lung tissue is consolidated, as in the early stages of tubercular phthisis, or as the result of pleuritic effusions or empyema, or by direct inflammation, as in an unresolved pneumonia, the life and healthful activity of the respiratory system is seriously impeded To expand these consolidated portions, and at the same time to deposit remedial and antiseptic agents in the inflamed lung cells, is the method and the theory of the treatment by the Pneumatic Cabinet

The Cabinet is practically an air-tight iron safe about seven feet high, two feet wide and two and a half feet deep, large enough, in fact, for a patient to stand or sit in In the rear is a heavy door fitted with bolts, but ingeniously opened and closed by a single turn of the hand In front is a large plate glass window, through which passes a gutta percha tube having a stop cock on the outside, and ending in a trumpet shape for receiving the medicated spray The tube within the Cabinet is fitted to a flexible rubber mouthpiece for the patient The patient enters the Cabinet and seats himself opposite the window The door is closed and the air is rarefied by an air pump to the desired degree as represented by the fall of mercury in a barometer connected with the inside of the Cabinet The degree of rarefaction is usually that represented by a barometric fall of from one tenth of an inch to an inch and a half, each tenth of an inch being equivalent to an altitude of 100 feet as regards the removal of external pressure from the chest walls The patient now inserts the inhaling tube in his mouth and compresses the nostrils with the fingers to prevent the escape of air through the nose, the stop cock is opened and the outside air rushes in, carrying with it the medicated spray, which is atomized by a powerful cylinder of compressed air The effect is a *forced involuntary inspiration* followed by a *forced voluntary expiration* These respiratory movements are continued for several minutes, but upon the least fatigue the stop cock is closed, the patient removes the tube from the mouth, and breathes the rarefied air of the Cabinet until ready for another application The treatment varies in duration from ten to thirty minutes, and is repeated either daily or at intervals of two or three days, the number of applications varying, the greatest number being 105—a case of acute catarrhal phthisis in Dr Williams' practice, which recovered

The peculiar value of this treatment lies "in the *combination* of the medicated spray with the increased strength of the inspiratory movements " A much fuller expansion of the chest is produced than is possible by an ordinary full inspiration, and at the same time the medicated spray being carried to the lung cells with much greater force than by a natural inspiration, is deposited in the very deepest and most remote portions of the lungs Antiseptic air thus administered, must condense under the increased pressure due to the active expiratory effort, and be deposited in cavities or other diseased portions of the lungs

---

[1] Introduced to the profession by Dr Herb F Williams of Brooklyn N Y See article in New York Medical Record Jan 17 1885

At the same time one must not neglect to consider the beneficial effects of removing the external pressure of the atmosphere from the chest walls In the first place, the active and passive movements of the respiratory act being reversed, the breathing takes place not merely with the ordinary *tidal* volume of air (which is carried by inspiration only to the trachea and larger bronchial tubes, reaching the lung cells in obedience simply to the law of the diffusion of gases), but also with the much larger volume of *complemental* air When properly conducted therefore, a calisthenic action is produced which expands and develops even the healthy chest, and which is beneficial from a mere hygienic standpoint Indeed, spirometric tests before and after a course of treatment, have demonstrated an increase in vital or volumetric capacity of from twenty-five to one hundred per cent, and a corresponding development both of chest measurements and of chest expansion The removal of the external pressure causes moreover such an expansion of air in the bronchial tubes as forcibly to expel secretions, which may have so accumulated as seriously to impede the proper expansion of air vesicles Finally, the influence of this treatment upon the circulation is very instructive and worthy of the most careful study We know that in ordinary inspiration, arterial tension is increased while in expiration it is correspondingly decreased In forced respiration, in a rarefied atmosphere, the proportionate difference between the blood pressure in inspiration and in expiration is increased, the main arterial pressure is increased, but the capillary blood pressure in the lung tissue is so far decreased as actually to decrease the liability to pulmonary hæmorrhage

This modification of the capillary blood pressure can scarcely be other than beneficial to any inflammatory process in the lung tissue The danger, however, should not be overlooked that with fatty hearts, aneurismal dilatations, atheromatous arteries and denuded arteries lying in cavities of the lungs, the most serious or even fatal injury might be done by a careless or ill-advised use of the Cabinet This, however, is no argument against the value of the treatment, it is, in fact, a direct argument in favor of its power over lung expansion

The principal agents thus far used in the spray have been the bichloride of mercury, iodine, carbolic acid and phenyl "While the evidence," says Dr Williams, "is strongly presumptive that the use of these germicides diminished the quantity of bacilli in several instances and obliterated them in others, the opportunity for following out this line of inquiry has not furnished sufficient data to permit an unqualified statement" To kill bacteria is one thing, to kill germs is another, and all evidence seems to point to the fact that it is impossible to keep germs out of the body What then can inhalations do?

Several years ago, Prof Tyndall made some interesting studies on this subject, and discovered that although by a continuous boiling he could not sterilize solutions, he could sterilize them by many successive boilings Although he might not at once destroy the fully-developed bacteria, he could destroy their offspring while they were too young to produce a fresh generation It is true that this may be only a theory, but it is a theory which will I think stand the test of experience and it is the theory underlying the treatment by antiseptic inhalations

The materials which have been found most useful as antiseptic inhalations are not mere gases which are mingled with the inspired air and then pass out with it, but they are vapors of soluble bodies which are deposited upon lung tissue Upon every moist bronchial tube, upon the walls of cavities and around, if not in, congested areas the inhaled vapor is condensed *to render the soil barren for germ growth* "For if the difference between a soil fit and one unfit for bacterial growth is to be measured, for example, by the difference between the functional activity and resulting vital resistance of an upper and a lower lobe of the lung, surely it is not unreasonable to hope that by impregnating the pulmonary tissues with antiseptic material which we know renders them less fitted for the cultivation of bacilli, we may be able to make up the lacking resistance and so prevent the access of disease"[1]

For a further confirmation of the proposition that by discontinuous antiseptic inhalations bacilli can be made to disappear from the sputa, the reader is referred to a very interesting paper read by Dr V Y Bowditch before the Suffolk District Medical Society, Nov 11, 1885

The effect of these inhalations in the Cabinet upon the *cough* depends upon the lesion in the lung In nearly every case reported by Dr Williams, and in all of the cases that I have been privileged to see, the cough and expectoration have been much reduced, there has been an increase of appetite and of weight, a tendency to a more restful sleep and a reduction of the fever Indeed it can be safely claimed that where fever is due to the absorption of pus from a lung cavity accessible to the air, the introduction of an antiseptic will as certainly reduce the fever as will the washing of a uterus in puerperal septicæmia, or the cleansing of any suppurating wound The cases that have thus far been reported have certainly given proof of the possibilities of recovery from serious lung lesions Of three cases of unresolved pneumonia, Dr Williams reports all cured, of seven cases of primary infiltration, six cured and one improved, of nine cases of acute catarrhal phthisis, four cured and one improved, while of nine cases of chronic fibrous phthisis, eight showed marked improvement

The danger when looking at such a history of treatment is, that inconsiderate enthusiasm may prevent one from fairly weighing evidence, which must in all justness be impartially considered It is our duty, however, as conscientious and progressive physicians, to investigate the subject carefully and without prejudice, patiently developing what is good in the method, and gradually learning what is its proper place in the healing art

---

[1] Solomon G Smith M D British Medical Journal Feb 23 1884

Thus far its greatest value seems to have been in the treatment of *early stages of phthisis*, in *fibroid phthisis*, in *chronic bronchitis*, in *emphysematous conditions* of the lungs, and in the *consolidations resulting from pleurisy, empyema, and unresolved pneumonia* Upon the Continent of Europe, the applications of compressed air have proved of inestimable value in the treatment of *asthma*, and it is not improbable that similar successes may soon be recorded here To meet these various indications, an ingenious mechanism attached to the Cabinet permits the operator at will either to rarefy the air within the Cabinet to a given degree, or to compress it to a given degree, or alternately to rarefy and compress it synchronously with the respiratory act

Our only method of determining the merits of the treatment is by a careful study and a complete record of all cases I trust to be able soon to report some original investigations upon the subject, studying it in its relations to and effect upon the healthy organism as well as the diseased

194 West Brookline St , Boston, Mass

RUPTURE OF THE RECTUM, AND PROLAPSE OF THE SMALL INTESTINE[1]

BY S B LYON M D,

GOVERNMENT HOSPITAL FOR THE INSANE WASHINGTON D C

I desire to present some notes on an unusual case of rupture of the rectum, and protrusion of a loop of the small intestine through the opening in the wall, and from the anus

The patient was a woman of 50, suffering with melancholia of a very active type, accompanied with delusions largely relating to the pelvic organs, she often fancied herself pregnant, or being delivered, and her conversation, which was almost continuous during waking hours, was on subjects forbidden in polite society She had a remarkable talent for making remarks exceedingly embarrassing to both the physician and the nurses One result of her delusive ideas of her pregnant condition, was a disposition at times to assist nature by introducing her hand into her vagina or rectum, and pulling or working at those organs, so that a tendency to prolapsus of both uterus and rectum existed, and these conditions had been reduced more than once The disposition to interfere dangerously with herself made constant watchfulness and some restraint necessary

A few days since, when visiting the ward, the nurse called my attention to a mass of viscera which had descended from the anus, and an examination showed at once that it was not a question of a prolapsus of the rectum, such as had previously occurred, but that the protruding mass was made up of a part of the small intestine, and the appearance of omentum and the serous surface of the gut excluded a mere turning inside out Only a rupture of the large intestine and the protrusion through the opening thus made of the small gut, could explain the condition The rectum, with its internal and external sphincters, was in its normal condition, not even slightly prolapsed by the weight and tension of the protruding mass

Ordinary modes of reduction were attempted, but with no success, the weakened condition of the woman from shock, and long continued exhausting excitement, precluded surgical interference Within forty eight hours death resulted without any sthenic symptoms The following is Dr Blackburn's report of the autopsy

"Mrs ——, age 50 Chronic melancholia On opening the abdomen a peritonitis of the folds of intestine in the pelvic region was revealed The peritoneal surfaces in that region were agglutinated by recent lymph, and a moderate quantity of reddish serum, with floating lymph was contained in the cavity On further examination a rupture of the anterior wall of the rectum within the recto-uterine pouch (Douglas's) was discovered Through this opening a large loop of the ileum, with its mesentery, had passed No escape of fæces had occurred, as the intestine was adherent to the edges of the rupture The portion of the intestine protruded began about six inches from the ileocœcal valve, and was about eighteen inches in length The loop was discolored and covered with lymph Some strangulation had occurred, shown by the thickening of the intestine and the discoloration of the part Examination of the vagina and os uteri revealed an old laceration of the os, and erosion of the posterior lip of the cervix "

The only mention I have seen of a similar condition is under the head of hernia, as "Hedrocele," in Gross's "Surgery," where he quotes Dr Uhde, of Brunswick, but no sack existing in the present case, it is doubtful if it is described under "Hedrocele "

MEDICAL PROGRESS.

MATERIA MEDICA AND THERAPEUTICS

The Hippurates of Lime and of Lithium — Dr V Poulet considers the hippurate of lime as the best preparation of calcareous salts for use in the system, and as especially useful in affections of the urinary passages, in affections of the liver, in diseases of the skin and mucous membrane, where they are dependent upon functional vices of the liver or upon lymphatism, in a great number of diseases of the alimentary canal, both of the stomach and intestine, in diabetes, and in chronic rheumatism, gout, etc

In urinary affections, the subacute cystitis of the neck of the bladder yields satisfactorily to its use, with relief to the frequent desire to urinate, pain on urinating, etc In certain cases where the urine manifests an abnormal alkaline reaction it becomes promptly acid again by the use of this drug In every case, there is a return to the normal limpidity and a cessation of the presence of the mucous globules It is quite as useful in urinary lithiasis from whatever cause, phosphaturia, uraturia, or oxaluria If the theory of the liver as the principal seat of the formation of uric acid, as a product of the disassimilation of the hepatic tissue, be correct, it follows that this drug, acting, as it does, through the hepatic gland, should be especially indicated.

---

[1] Read before the Medical Society of the District of Columbia October 14 1885

In diseases of the liver it gives marked results, either by relief or cure, even when the symptoms are pronounced and decided, having progressed to the production of ascites and œdema of the lower extremities. This applies to subacute hepatitis, chronic hepatitis, catarrhal icterus, hypertrophic and even atrophic cirrhosis in its early stages, biliary lithiasis, certain functional disorders occasioned by hydatid cysts of the liver etc. Surgery is benefited by this drug in traumatic or other urinary fistulæ, by modifying the composition of the urine.

In skin diseases, exclusive of those of parasitic origin, whether they come from the tuberculo scrofulous, or the neuropathic diathesis, the hippurate of lime is useful, exercising an alterative and tonic action. The arthritides Dr. Poulet considers symptomatic of an affection of the liver—such are pemphigus, and certain urticarias. "With the hippurate of lime, *no more red noses*. In America, where this affection is so common and is the despair of a part of the population, there is no doubt but that this remedy will soon be appreciated at its proper value."

In dyspepsia and diabetes this agent seems to be especially applicable to inflammatory gastric or intestinal dyspepsias with flatulence and reflex phenomena commonly called sympathetic. It relieves the constipation very satisfactorily. In diabetes, as a simple solution, and with the aid of the ordinary dietetic regimen, it acts very beneficially.

In affections of the mucous membrane, it is admirably adapted to all cases of gastro intestinal acidity, to ulcer of the stomach, chronic enteritis, muguet, and to tympanites. In the diarrhœa of infants it produces remarkable results. In chronic rheumatism, gout, difficult dentition, etc., it is useful with phosphate of soda.

The hippurate of lithium, alone or combined with the hippurate of lime, serves admirably in the treatment of gout. The attacks of gout are lessened in intensity and frequency. The tophus is redissolved. The nodosities and chronic engorgements, in both the larger and smaller articulations, gradually disappear.—*Bulletin Gen. de Therapeutique*, Aug. 30, 1885.

SULPHATE OF IRON IN CATARRH OF THE STOMACH IN YOUNG CHILDREN.—DR. ROTH says, in the *Pester Med.-Chir. Presse*, that one of the most important symptoms of catarrh of the stomach is the acidity of the contents of the stomach and bowels. The vomited matters have an acrid odor, and take on a greenish color; it is the same with the contents of the intestine. The parts soiled by these matters, the anus and scrotum, become red. The green color has been wrongfully attributed to the use of calomel. Absorbents have been used to destroy the acids with tonics to combat the catarrh. But too often these remedies have not responded properly. In such cases Roth uses sulphate of iron, which exerts a multiple and favorable action. It is especially a disinfectant. The stools change their color and lose their bad odor. As an astringent, the sulphate of iron contracts the turgid mucous membrane and coagulates the albuminoid substances; to have its proper effect, the use of the drug should be continued for several days. Dr. Roth uses the following formula:

Sulphate of iron, 0.1 gramme, mucilage of gum arabic and simple syrup, each 20 grammes; a coffee spoonful every two hours.—*Revue Mensuelle des Maladies de l'Enfance*, Sept., 1885.

ANATOMY AND PHYSIOLOGY

INFLUENCE OF PILOCARPINE AND ATROPINE ON THE SECRETION OF SWEAT.—The Paris correspondent of the *British Medical Journal*, Aug. 1, 1885, states that M. JUDIC, in a communication on the influence of pilocarpine and atropine on perspiration, made before the Biological Society, stated that if a dog's spinal cord be cut between the eighth and ninth dorsal vertebræ, its paws become the seat of intense perspiration. This appears to prove that there is a spinal nerve centre, which regulates the secretion of sweat. After dividing the sciatic nerve, if the peripheral end be stimulated, the corresponding paw perspires profusely. The sciatic nerve is simply a transmitting agent; it establishes communication between the medullary and the peripheral nerve centres. If, instead of stimulating the peripheral end of the sciatic, the nerve be left intact, and pilocarpine be administered to the animal, the perspiration is equally intense. If the nerve be cut and pilocarpine administered, the perspiration is normal. It may, therefore, be concluded that pilocarpine does not act on the glandular elements, but on the nervous system. Atropine produces the opposite effect to that provoked by pilocarpine.

MEDICINE

ACUTE ENCEPHALITIS OF CHILDREN.—The diffuse inflammatory affections of the cerebral tissue in children are enveloped in mystery, even if they ever occur. STRUMPELL has investigated what he calls the acute encephalitis of children. He endeavors to assimilate infantile cerebral paralysis to the well-known spinal paralysis of children. Acute poliencephalitis is the counterpart of acute poliomyelitis. These affections attack the gray matter of the nervous system, on the one hand it is the cerebral cortex, on the other the anterior horns of the spinal cord. In autopsies of children dying with cerebral paralysis it is not uncommon to find cicatricial wasting of the motor areas of the cerebral cortex. These morbid conditions are sometimes congenital, when they are regarded, probably on insufficient grounds, as simple atrophy. Strumpell believes that many of the cases originate in acute inflammation of the gray matter. According to him, clinical experience further proves the analogy between the acute poliencephalitis and acute poliomyelitis. Strumpell has observed twenty-four cases of acute poliencephalitis at ages varying between four weeks and six years. Seven cases were under one year of age; eight occurred in the second year, and four in the third of life. The causes are said to be obscure, but the progress of the cases is characteristic The onset is rapid, with the general symptoms of fever and vomiting something akin to meningitis Convulsions are observed on both sides of the body, and consciousness is lost The initial stages may last only a few days, or may be prolonged for two weeks, or even two months The author believes that death may happen in the first period, though he has no proof of this occurrence in his own experience There is but little gradation between the febrile period and the second stage, or paralytic period The general condition of the child rapidly ameliorates, and then the hemiplegia remains as a sort of surprise for the physician The hemiplegia is more marked in the upper than the lower limb, it rarely attacks the face, but strabismus has been observed several times Sometimes there is monoplegia only Anæsthesia is not observed The palsy does not remain at its worst, and though there is no rapid wasting of muscle, yet the limbs are arrested in growth As a further contrast to the spinal palsy, the muscles, even if there be no definite contracture, are yet in a state of tension Strumpell does not omit to mention the occurrence of symptomatic epilepsy, first unilateral, then general He speaks also of the development of athetosis There can be no misgivings as to the nature of the disease that Strumpell writes about, and even his description of its clinical aspects is not complete But the chief interest to neurologists is the pathology of this so called infantile hemiplegia We think it not unlikely that some cases of this disease may own the same pathology as poliomyelitis acuta *A priori*, we can think of no reason why this should not be the case But the pathogeny of acute poliomyelitis is unsettled, though there can be no question that in some cases the signs of inflammation are too marked to be overlooked A theory which requires careful consideration, and which might be tested whenever possible in the dead house, is that of thrombosis of the veins of the cerebral cortex, this view has been put forward by Gowers, in his "Diagnosis of Diseases of the Brain"—*Lancet*, Aug 29, 1885

THE DIAZOREACTION IN PHTHISIS —In reply to the objections raised to the diazobenzoic reaction, GRUNDRIES has made a large number of experiments on sixty-four tuberculous subjects He first prepared two solutions

SOLUTION A

Sulphanilic Acid	grm	1
Nitric Acid	"	10
Distilled Water	"	1,000

SOLUTION B

Nitrite of Soda	grm	1
Distilled Water	"	200

To solution A he adds 25 grms of solution B He then mixes equal parts of this and urine in a test tube, adds a few drops of ammonia, and sets it aside for twenty-four hours The intensity of the reaction is measured by the color of the precipitate In feeble reactions the precipitate is a clear green, in strong reactions a dark green Sometimes there is a yolk of egg color, which seems to have no special significance The superposed liquid has a reddish tint, the intensity of which varies with the color of the precipitate

An intense reaction is a sign of advanced tuberculosis, when it occurs constantly When it is absent the situation is more favorable These tests are easily made, and are of great prognostic value —*Zeits fur klin Medicin*, Bd VIII, Hft 4

SURGERY

SUGAR-DRESSINGS —DR F FISCHER gives a long and interesting summary of the results of this mode of treatment in the surgical clinic at Strasburg, as used by Prof Lucke and himself Finding the sublimate solution to be unsuitable in many cases, in the beginning of the winter semester of 1883–4, they tried a mixture of naphthalin and sugar in equal parts, and then a mixture of iodoform and sugar (one part iodoform to ten parts of sugar) The naphthalin-sugar was soon abandoned, the iodoform sugar was confined in its use to such cases as presented tubercular changes The use of sugar in preventing decay and suppuration in wounds is old, Galen refers to it, and Dr Fischer quotes various authorities since his time, he refers, among others, to Packard (*Am Journ Med Sc*, 1865) as using it in hospital gangrene In his experiments he has kept hydrocele fluid eighteen days, preserved by a solution of sugar, blood serum eight days Animal infusions that are alkaline in reaction become acid in four or five days, on standing Mixed with a thick syrup they can be kept a month without showing bacteria or vegetable mould This fact led to the conclusion that in an acid secretion bacteria could not live in any number, and consequently, that the use of sugar with the dressings, after the disinfection of wounds by the sublimate solution, would prevent any disturbance by foreign substances

To apply the sugar to wounds, small bags of muslin were made, the muslin being prepared by boiling and soaking in soda solutions, and washed until it no longer gave an alkaline reaction, the sugar being placed in them, they were laid upon the wounds and covered with wood-wool All the ordinary antiseptic precautions were taken, however, in performing operations and treating wounds, and before the sugar was applied the sublimate solution was used to cleanse the wound The layer of sugar over the wound was made at least two cm thick, then came gutta-percha paper, which with the muslin and wood-wool completed the dressing This sugar dressing remained eight to fourteen days undisturbed If the secretion was moderate, the sugar retained it, if greater, it formed with it a crust, was the secretion excessive, new sugar sacks were placed in position and retained by folds of muslin

The healing process in most cases went on without fever, a record of 38° C was rarely reached A temperature of 38° C was a sign for the renewing of the dressing, even when the patient felt well Granulations spring up quickly under the sugar sacks, and the wound preserves a healthy appearance The number of cases so treated and recorded reach 202, of these five died One was a case of erysipelas after amputation of the breast, a second died of hæmorrhagic nephritis, a third, amputatio in studio septico, died in a few hours after the operation, the fourth and fifth with pulmonary phthisis. In extensive suppurations, such as phlegmons, empyema, etc., this dressing is not suitable, as the sugar is dissolved by the profuse secretion and causes much discomfort to the patients. Sugar acts admirably as a deodorizer in unhealthy wounds, ulcers of the leg, ichorous carcinoma, etc., after thorough disinfection with the sublimate solution, the sugar being laid on thickly; after two or three dressings the odor is entirely removed.

He recommends the sugar dressing, that is so easily applied, particularly for all wounds closed by nature, for these healing by first intention, for ulcers in order to stimulate healthy granulations, and for all slight wounds, particularly of the hand and superficial contusions.—*Deutsche Zeitschr. für Chir.*, Bd. xxii. Hft. 3 and 4.

THE SURGERY OF THE LUNGS.—DR. TRUC, in a thesis discussing the present status of surgery of the lungs, shows that pneumotomy partial or total, practised antiseptically, is generally well endured by the different animals and is compatible with life.

In general applied to the treatment of tuberculosis, the operation has hitherto given deplorable results, while as an operation for secondary cancer of the lung, circumscribed and superficial, it seems useful and little dangerous.

The operation may be further advantageous:

1. In certain abscesses producing serious complications, their location being well established.
2. In circumscribed abscesses producing infection, their location being exactly determined.
3. In localized severe putrid bronchitis.
4. In rare forms of limited tuberculosis, represented by an insolated superficial cavity, the septic products of which occasion septic symptoms which directly endanger the life of the patient.
5. In large hydatid cysts, which are not spontaneously relieved, nor lead to the ordinary methods of cure.
6. In cases of intrapulmonary foreign bodies which have resisted ordinary means for their removal and produce inflammatory symptoms or destruction of the parenchyma, their locality being known with precision.

Dr. Truc further concludes that exploratory puncture, carefully made, is generally harmless, and frequently of great diagnostic value.

For the operation the thermocautery is to be preferred to the bistoury, as being less dangerous, and costal resection should be generally performed as a convenient means of opening large cavities, and for facilitating cure. As adjuvants to the operation, antiseptic irrigations seem always useful and frequently necessary. Uncombined with pneumotomy, antiseptic injections seem but little beneficial.

As to intraparenchymatous in tubercular diseases, when carefully made with fluids but slightly irritating and in moderate doses, they are well endured, and while they neither aggravate the local condition nor arrest the progress of the pulmonary lesions, they in some cases seem to ameliorate the symptoms of the patient. For making such injections, the axillary and subclavian regions are to be selected as being most accessible and least dangerous.—*Revue de Thera.*, Oct. 15, 1885.—*Med. News*, Nov. 7, 1885.

FRACTURE OF THE SPINE: RECOVERY.—At the meeting of the Border Counties Branch, on October 1st, DR. CRERAR reported the case of a man, aged 27 years, who was working six years ago as a miner in a coal pit, and in a stooping position, after the manner of colliers, when a heavy piece of "metal" fell from the roof and struck him with great force on the back. He was carried home carefully, and Dr. Crerar first saw him lying on his back upon the floor. He had complete power over the lower limbs; but, on examining his spine, it was found to be fractured and partially dislocated, the injuries involving the eleventh and twelfth dorsal and the first three lumbar vertebræ. The injuries were very distinct. Dr. Crerar expected paralysis of the parts below the injury in a few hours, but, as the cord seemed to have escaped, a hope was expressed that the man might possibly recover. He lay on his back about eight months, nearly losing his penis at one time by sloughing, but he made a good recovery. The seat of the injuries was very apparent on October 1st, 1885, a good deal of callus having been thrown out. He had married since the accident, and had become the father of a family. He was strong and well, working every day as a coal miner without any inconvenience. Seeing that so few who had sustained fracture and dislocation of the spine recovered, this case appeared to be one of considerable interest.—*British Med. Journ.*, Oct. 17, 1885.

OBSTETRICS AND GYNECOLOGY

UNCONTROLLABLE VOMITING DURING PREGNANCY, CURED BY FEEDING THROUGH AN ŒSOPHAGEAL TUBE.—BRUNNICHE, *Hospitals Tidende*, 1885, No. 29, reports the case of an unmarried woman with scanty, irregular menstruation, who, suffering severe gastric disturbance for two months, entered a hospital, and, under diagnosis of ulcer of the stomach, the possibility of pregnancy was denied. Soon after admission, vomiting became so severe that all food was rejected and inanition was threatened. Alimentation by means of an œsophageal tube was now resorted to, and broth, followed by cold water, before the withdrawal of the tube, was first fed to the patient without causing vomiting. Milk was then administered, and no vomiting being produced, was followed by bouillon, etc., with like favorable result. After five days an attempt to swallow food caused reappearance of nausea and vomiting, and the use of the tube was again necessitated. Pregnancy was now readily diagnosticated. In three weeks the use of the tube was dispensed with, and the woman discharged cured.

A significant fact in connection with the case is that it was only necessary to introduce the tube into the entrance of the œsophagus, showing that the location of the sensitive region, irritation of which occasioned the vomiting, was situated higher up in the digestive tract than the stomach.—*Centralbl. für Gynak.*, Oct. 10, 1885.—*Med. News*, Nov. 7, 1885.

THE
Journal of the American Medical Association
PUBLISHED WEEKLY

THE EDITOR OF THIS JOURNAL would be glad to receive any items of general interest in regard to local events or matters that it is desirable to call to the attention of the profession Letters written for publication or containing items of information should be accompanied by the writer's full name and address although not necessarily to be published All communications in regard to editorial work should be addressed to the Editor

SUBSCRIPTION PRICE INCLUDING POSTAGE
PER ANNUM IN ADVANCE $5 00
SINGLE COPIES 10 CENTS

Subscriptions may begin at any time The safest mode of remittance is by bank check or postal money order, drawn to the order of the undersigned When neither is accessible remittances may be made at the risk of the publishers by forwarding in REGISTERED letters

MEDICAL STUDIES AND MENTAL TRAINING

In a recent number of the *British Medical Journal* are two "Introductory Addresses," delivered at the opening of medical schools in Great Britain In themselves the addresses are worth reading and worthy of thought By the strong contrast of views, however, they are still more apt to hold the attention and provoke comment In both, the subject treated of with greater or less detail was the kind of studies most profitable for youths to pursue, and especially such as intended to make medicine their profession

In one of these addresses MR JONATHAN HUTCHINSON speaks plainly his own conviction that radical reform is needed in the choice of studies He would make a distinction between the kinds of knowledge to be acquired by the people in general, and by those who have special aptitudes The latter may follow with advantage almost exclusively a special line of study The majority, not thus endowed with special aptitudes, should choose to learn that kind of knowledge which will be most fruitful to them, and should acquire as much general information, even at the expense of its being somewhat superficial, as possible A choice in the kind of knowledge to be acquired must be made, he urges, because there is a limit to the powers of memory And when this limit is reached, if an attempt be made to acquire more it is only accomplished by crowding out and losing something already learned Upon this limitation of the human mind he dwells particularly, and urges on that account that the knowledge that we acquire should be carefully chosen, and often, if we do not wish to lose something already learned, we must abstain from taking up new and wholly independent subjects He thinks that far too much time is devoted to the study of Greek and Latin, that "it would be a great gain if the dead languages were forthwith honorably buried "

In reply to points usually urged in favor of these languages, namely, that they tend especially to develop the mind, that they are keys to invaluable literatures, and that they are necessary for a sound comprehension of our own language, especially the terms of science, he says "The study of language for the most part is a pure matter of rote memory, and encumbers rather than strengthens the mind," that there are now abundant means for acquiring a perfect knowledge of ancient life, history, and literature without first learning the languages of the time In regard to the last argument in their favor, he regrets its reality, but believes "a good vocabulary is sufficient It is not necessary to study grammatical construction in detail " Even the modern languages he would not have acquired until they are needed for actual use by the individual He looks upon them as burdens to the memory, and unnecessary burdens often All language he regards as a means to an end, and not an end in itself, a means for the acquisition of knowledge He would have all who do not possess special aptitudes for language and the studies dependent upon them, devote their time to the more fruitful studies of nature and man How much better it is to understand the causes of some of the great events of French history rather than to know ever so well the irregular verbs of the language "The one kind of knowledge is living, is in itself fruitful in incentives to sympathy, to action, and to vigor in social life, the other is, for the most part, dead and abortive "

In strong contrast to these views are those expressed by PROFESSOR E O SCHAEFER, of University College, London The preparation which he looks upon as best for the man intending to follow a liberal profession, is the ' classical" course so long looked upon as essential for the education of an English gentleman For one intending to pursue medicine as a profession, he would have this course supplemented by a year or so devoted to the study of physics, chemistry, and biology, before the more purely medical branches are taken up

The great difficulty in all past and in most present educational methods, is that all minds are put in the same mould, with the expectation that similar results or finished products will result We might as well attempt to cast a statue in gold, silver, bronze, iron, and lead, and expect the mould to turn out exactly the same product with each metal As with metals, so with men's minds, there are the greatest differences in quality and character, which adapts each to form different products, and if each is properly fashioned and utilized for the production of that for which it is best adapted, we will obtain the best results The study of the classics should not be demanded of any man who wishes to be looked upon as educated, any more than a study of science is demanded of all A good, a liberal education does not consist in the study of any one prescribed course What is needed by every well educated English speaking person, whether he intends to study medicine or not, is a good, a full, a complete acquaintance with the English language As much time should be spent in practically teaching the distinctions between English words, in pointing out shades of meaning, as is now spent in pointing out the ability of Greek and Latin authors to make these distinctions in their own language

For those contemplating the study of medicine there is desirable, besides a training in study from books, in reading and acquiring knowledge by reading (and this is all important), a training in observing and in the methods of scientific reasoning Science, when properly taught, inculcates the most scrupulous exactness, veracity and attention to details, its methods of reasoning are those used most in everyday life And almost every problem presented to the physician for his solution must be solved according to these methods Undoubtedly the ideal physician should be a man of such breadth of mind that he can grasp, and such industry and ability that he can acquire much more than simply a knowledge of his profession He should be conversant with literatures and with sciences For the education of such a man a training in the classics is as necessary as a training in science But how few there are of this quality and character, and why should all then be put through the mould best adapted to him If they were, many years would be wasted, hard study and close application would not be indulged in, and therefore much mental training lost that might have been acquired had the studies rather been adapted to the tastes, talents and necessities of each student

A thorough understanding of the nature of English words is needed by every English-speaking person Therefore this should be demanded But for the training of the mind, the memory, judgment, power to reason, those subjects should be chosen which will easily enlist the attention of the student, and thus help him to make the application necessary for the mental training As means to an end, languages will be acquired with pleasure as they are needed For the study of medicine there should be required of the applicant at the college door a good English education, and evidences of a well-trained mind, whether the training has been obtained upon classical models or not In addition, as soon as a sufficient number of schools exist in this country suitably equipped for teaching physics, chemistry and general biology these should also be required before the study of the purely medical branches is undertaken

---

"SUCCESSFUL CASES OF PULMONARY PHTHISIS" REPORTED BY DR W H GEDDINGS, OF AIKEN, S C

In the *New York Medical Record*, of October 3, and 10, 1885, DR W H GEDDINGS makes a report of thirty eight cases of pulmonary consumption which are of such interest that we propose to consider them rather critically They are cited as examples of recovery, and are indeed a most gratifying proof of the fact that pulmonary phthisis is not necessarily a fatal disease Yet, we think that were one inclined to be captious, he would scarcely regard all of the cases as recovered However, the decision on this point depends upon the length of time during which there is entire absence of symptoms, which is considered sufficient to constitute recovery, as distinguished from quiescence Dr Geddings seems to regard in this light a cessation of all symptoms for two years, since that was the shortest time noted in any of his cases We have no desire to be hypercritical in this matter, yet it seems to us it would be a little more prudent to pronounce the disease quiescent when no more than two or three years have elapsed since the disappearance of the symptoms

A careful analysis of these thirty eight cases shows twelve in which less than five years has elapsed On the other hand, in the majority of these twelve cases, the probability of permanent arrest is greatly strengthened by the fact that careful physical exploration of the chest revealed more or less diminution in the area of consolidation While not inclined to assert dogmatically that a lapse of five years is requisite to the establishment of a case of pulmonary tuberculosis as cured, yet we would suggest that in forming a prognosis one should not lose sight of the frequency with which improvement occurs in consumption, even to a temporary disappearance of all symptoms Furthermore, that very hopefulness and inclination to view their disease lightly to which Dr Geddings refers may lead patients to overlook and omit to mention some trifling symptom which to the physician would be of ominous importance Dr Geddings undoubtedly employed every means to gain accurate statements from those patients who had passed from under his personal observation, and if, perchance, unintentionally the individuals gave too much of the *couleur de rose* to their condition, he is in no wise to be held accountable. The remaining twenty-six cases are strong and gratifying, particularly cases III and VIII, in which the disease has been arrested ten and fifteen years respectively.

Let us briefly consider Dr. Geddings' cases from the standpoint of those features of the disease which Jaccoud regards as conditions of its curability. These conditions have already been stated at length in an editorial article in the issue of this JOURNAL of July 4, 1885. According to Jaccoud, the probability of a cure is directly proportionate to the duration and extent of the disease. The thirty-eight under consideration had manifested the first symptoms but a few months, as a rule, before coming under Dr. Geddings' observation, although in some the commencement dated back two years or more. And in all but three, the disease was unilateral, for the most part confined to the apex. With the exception of three cases in which cavities were demonstrable, the disease had not progressed to the stage of softening, and therefore presented the conditions most favorable for recovery. The three cases in which there were cavities demonstrated the correctness of Jaccoud's view, that even in the third stage, pulmonary phthisis is susceptible of arrest. Although all presented more or less fever and night sweats, in only thirteen was the temperature stated as having reached 100° F. or over, while the sweating disappeared with considerable readiness, conditions justly regarded by Jaccoud as favorable to curability. Copious expectoration was noted in only two instances, and in all the quantity of *sputa* was diminished after the patient came under observation.

Only a small percentage of the cases was complicated by diarrhœa or other digestive disorders, a circumstance also mentioned by the distinguished Frenchman as favorable. In a few there was a marked degree of emaciation, although in all there had been a loss of weight. The rapidity with which this was regained in several instances was truly astonishing. There was a striking absence of serous inflammations and other complicating diseases, with the exception of pulmonary hæmorrhages. Hæmoptysis or hæmorrhage was recorded in eighteen out of the thirty-eight cases. The very large percentage in which this occurred, as Dr. Geddings justly remarks, seems to show that so far from proving deleterious, hæmorrhage, when not copious enough to dangerously exhaust the patient, actually preserves against inflammatory extension of the disease within the lungs, a further coincidence with the opinion of Jaccoud.

Erethism or high nervo-vascular excitability, considered by Jaccoud as an unfavorable condition, does not appear to have been present in Dr. Geddings' cases, unless the rapid pulse rate be an indication of its existence. In every instance the pulse was fast out of all proportion to the degree of the fever, remaining rapid in some instances even after the temperature had returned to normal. Acceleration of the pulse, however, is so uniformly present in tuberculosis, that A. Flint mentions it as one of the corroborative signs of the disease in its inception. In nine cases the fact of heredity was noted, and although it may have been a prominent factor in the causation of others, it is fair to presume that the most of them may be classed under the category of acquired phthisis, which is the form of the disease considered by Jaccoud to be most amenable to treatment. If the constitutional strength be sufficient to resist the first invasion, the disease is liable to break out again at any time, owing to the inherited diathesis. In this form of tuberculosis, therefore, the cure is but relative.

Altogether, the report of the cases under consideration is instructive and encouraging, the more so, since, so far as can be judged from the necessarily rather meagre details, the cases appear to fall under the category of those which, according to Jaccoud, are appropriately sent to stations of high altitude, of 3,900 feet or more, in Switzerland, and Aiken has a far lower elevation. It would be highly desirable if so skilful an observer as Dr. Geddings would study the cases which resort to Aiken with reference to determining and reporting the exact condition of those which are benefited by residence there. With definite knowledge as to the conditions on the part of the patient compatible with cure, either relative or absolute, it is certainly most desirable that as medical advisers we should also have precise, scientific data as to the climatic conditions, within our own land, that favor recovery in each case.

"HOW TO BUILD UP A MEDICAL SOCIETY."

Such is the title of a timely editorial article in a recent number of the *Maryland Medical Journal*, of which our only regret is that it was not longer. Our contemporary recommends that local societies should follow the good example of the Baltimore Academy of Medicine, which offers a prize for the best paper read before the Academy during the year. In addition to this, it is recommended that accurate reports of the proceedings of a society be made when they are to be sent to various journals in the country for publication

Of the two suggestions we regard the latter as the more important A reward for the best paper is undoubtedly a stimulus to writing good papers But the experience of our school days should remind us that comparatively few compete for honors and rewards The fact that a paper, or a discussion of a paper, is to be published, is, we think, a greater incentive to careful writing and speaking than a reward Be this as it may, the two things are by no means incompatible—the reward may be offered, and the "publication committee" appointed at the same time It is reasonable to infer that the offer of a prize will bring out at least half a dozen excellent papers in a year in a society with two or three hundred members But why not, at the same time, reward the member who gives the best discussion of a paper? In many cases the discussion is of more value than the paper itself Americans are said to be ready speakers as a rule If the saying be applied to the members of medical societies, however, it falls far short of the truth Very many—the majority—of the printed discussions of papers, read before medical societies, are exhilarating to the last degree when compared with the memory of the verbal delivery As a matter of fact, very few physicians are ready speakers, as shown by the hopeless floundering at annual banquets, and the usual distressing *finale* One of the best debaters, best lecturers, and most pleasing man to listen to when on his feet, is an eminent American gynæcologist who was once accused of having taken lessons in elocution for the purpose of filling his lecture room It is interesting to know that he always lectures to packed benches, while his accuser can usually count his hearers without trouble

It may be said that every man cannot be an orator But medical societies have no need of orators, they need men who can make short, sensible, pointed comments on papers—and give place to others, they need men who can remember what they have already said, and what others have said, and who will not waste time in wearisome repetitions They also need men who can appreciate the salient points of a subject or paper, and who can bring them out without linguistic ambiguity or ungrammatical attempts at flowery speech There are such men, and the number is just sufficient to show what results might be expected if there were more Still further, it must be evident that a speaker cannot interest his hearers unless he has a good idea of what he wishes to say—and a clear idea of his subject Nevertheless, we not infrequently see men arise, to discuss a paper, having neither of these qualifications It is not at all discreditable to preserve a judicious silence under these circumstances It is not too much to say that a member of a society should invariably prepare his discussion of a paper—so far as possible—before going to the meeting of the society, unless he has the subject and his remarks literally at his tongue's end Many who in private conversation show no symptoms of aphasia or other disorders of speech, seem suddenly attacked with amnesic aphasia, ischophonia and bad grammar when speaking in public Their tongues are not sufficiently loose, while their statements are too much so, sentences and conclusions are alike *non sequitur*, they are extremely prodigal in the use of ill chosen words, and exhibit a marked tendency to wander off into a labyrinth of side-issues

In this connection we may aptly quote from the recent report of the Editor of the Chicago Gynecological Society to the Society "Remarks made in the heat of discussion, are not always characterized by accuracy of statement Ideas are not always expressed *clearly*, *distinctly* and *adequately* Notions are frequently *obscure* and *confused* Then there exists in the minds of many medical gentlemen a supreme contempt for the science of the formal or necessary laws of thought The American medical mind evinces a natural fondness for the universal proposition, affirmative or negative Major premise, minor premise, and conclusion, are frequently in utter defiance of the laws of syllogism Fallacies—logical and material—exceed, in number and degree, those described by such systematic writers as Sir William Hamilton and John Stuart Mill The 'accidence and syntax' of English grammar is not always observed, and Dr Campbell's canons are sometimes held in derision " This is certainly not a flattering picture, yet it is not overdrawn The men who would not blush to see their extemporaneous remarks printed as spoken are few, and in the few must be included some who would not recognize the errors even in print

What are the remedies for these evils? 1 There is a prophylactic remedy which can be directly applied only by the medical schools—the insistance upon a proper preliminary education for the study of medicine, which should include *English*, even to the exclusion of the cut-and-dried classical education 2 Each medical society, which sends a report of its proceedings to the journals, should have a competent editor and publication committtee, whose duties should be (a) to judge whether a paper has sufficient merit to be read in the society, thereby cutting off worthless papers Some seem to have an idea that the road to practice and reputation is smoothed and leveled by a large number of "papers" They have one for every alternate meeting of the local society, and their only regret is that the society does not meet every evening, (b) to send out official reports of each meeting, and to twist the discussions into plain English when possible (when not possible to omit them), (c) to send out abstracts or *resumes* of the papers to be read, in order that the discussions may be prepared previous to the meeting, as far as possible, and thus be more interesting and valuable

---

One point more Every physician should consider it his duty to belong to at least one medical society, and his second duty is to attend the meeting Very many physicians seem to regard membership in a medical society as something accidental or incidental to professional life, rather than as a duty which each one owes to himself and his profession For example, of the forty-three or four hundred regular physicians in Illinois, there are not two thousand who are members of medical societies This is certainly a very bad showing for members of a "learned profession" But the same is true of almost every State in the Union From one county in Illinois, with twenty-four regular physicians, we learn that "there is no medical society in this county The profession is divided" The "divided profession" should remember that a society is for the good of the whole, as well as for the benefit of individual members

---

We have received bulletins from the National Board of Health, containing an abstract from consular and other reports concerning the prevalence and progress of yellow fever, smallpox and cholera in Canada, Mexico, Cuba, the West Indies, Venezuela, England, Brazil, France, Spain, Italy, Russia, India, Ceylon, Japan and the United States From March 4 to September 28, the deaths from cholera in Spain were 98,929 in a total of 267,689 cases, or 36 9 per cent In Colombo, Ceylon, there were twenty-two cases and twelve deaths from cholera between August 22 and September 12 For the week ending October 22 there were twenty-five cases of yellow fever in Havana, and twelve deaths

---

Professional Vacancy —By the recent death of Professor George Hunert, A M, M D, the chair of Theory and Practice of Medicine in the Medical Department of Wooster University, Cleveland, Ohio, is made vacant

SOCIETY PROCEEDINGS

MEDICAL SOCIETY OF THE DISTRICT OF COLUMBIA

Stated Meeting, October 7, 1885

The President, W W Johnston, M D, in the Chair

Dr T C Smith read a paper on

THE UTILITY OF DRY DRESSINGS

(See page 534)

Dr S S Adams said he thought Dr Smith's treatment of eczema was admirable in some cases In many, however, it would be difficult to keep the powder on the patient Dr Smith should first use a poultice in order to remove the crusts If he puts powder on the crusts and then more powder, and keeps piling on the powder, he will soon have crusts like those of eczema impetigonoides Dr Adams thought the first step in treatment should be the shaving of the head in such a manner as to remove the crusts Then if the doctor so desired he might apply his powder The speaker, however, thought it better to use ointments In his cases eczema had promptly yielded to ointments properly applied He generally used the white precipitate, with cosmoline, or vaseline The trouble usually consists in the difficulty of overcoming the whims and prejudices of both children and parents In the treatment of intertrigo podicis he used calamine and oxide of zinc in rose water As for varicose ulcers, probably rest and bandages did as much for Dr Smith's cases as his powder Dr Adams doubted if there was any special efficacy in treating nipples with dry dressings

Dr Frederich was glad Dr Smith had introduced the subject of dry dressings The speaker thought powders were of much advantage in the treatment of the wet stage of eczema All scabs, however, should be removed by softening with oil or poultices In many cases starch alone has proved efficacious after all manner of ointments had failed In the treatment of wounds iodoform stands pre-eminent

Dr J M Toner said that in the treatment of acute eczema the black wash had proved very efficacious in his hands When there is danger of salivation from long continuance, he uses lime-water alone He instanced a severe case which came under his observation some months ago, where great relief was afforded by such treatment

Dr C E Hagner said Dr Toner's patient was a woman 45 or 50 years old, who had been under the speaker's care The eruption came on suddenly and covered her face and arms It was also on other parts of the body On the second day her head was dreadfully swollen and her face presented the appearance of one suffering from erysipelas Dr Ford Thompson was called in consultation Lead water was used, and anodynes, quinine and Fowler's solution were given internally One morning, however, Dr Hagner got a note stating that his services were no longer required, and he afterwards learned that Dr Toner had cured the patient

Dr **Toner** said he had cured many other patients with the same simple remedy In the treatment of sores in the nasal passage, he put the patient flat on his back, and warming some of the black wash in a a spoon, introduced it gently into the nares

Dr **Berman** suggested that if the doctor made the patient say "*he*" when the fluid reached the pharynx, none would enter the stomach

The President knew of no disease more difficult to treat than eczema It had, indeed, become almost a reproach to the profession The purpose of all treatment is to make a new skin The disease is located in the papillary layer of the skin There is hyperæmia of the blood-vessels, and a constant migration of white corpuscles, which results in an enormous manufacture of epithelium No treatment will avail until these vessels are made to contract The smearing of ointments or the dusting of powders will not produce this effect The water treatment, which makes a pulp of the skin, removes not only the dead epithelium but also the young epithelium, and reduces the skin to a likeness to mucous membrane It softens the cuticle and keeps it softened When the eczema affects the hands and face the water treatment is still more difficult of application But by the use of masks much may be accomplished Strange to say, in many cases water seems to act as a poison, and increases the hyperæmia This is remarkable, as all cases are the same histologically The speaker thought in all cases constitutional treatment should be given, and every patient put in the best possible physical condition Special attention should be paid to the digestion, both primary and secondary, and by these means many patients, particularly children, will be relieved Teething infants will often suffer from an eczema which will disappear when dentition is completed

Dr **Frederich** said, in regard to the water treatment, that Hebra had constructed a water-bed, in which he kept his patient's body constantly submerged in ever changing water If the water is found not to agree with him, he is taken out and covered thoroughly with starch When the face and beard are affected the emplastrum vasel plumbicum is applied, and the patient's face covered with a mask, the dressing being removed every twenty four or forty eight hours

Dr **Schaeffer** said that ointments served a good purpose by excluding the air, even if they were not beneficial in any other way

Dr **Hagner** said eczema was a catarrhal condition of the skin, and like every other catarrh required sedative or stimulating treatment, according to circumstances No one remedy will cure all cases, and no inflexible rule of treatment can be given

Dr **S S Adams** said the cases which proved so obstinate and which were said to have been treated by so many physicians, were usually not properly treated at all The water treatments he considered difficult of application, and expensive

Dr **Johnston** acknowledged the difficulties of treatment by water The doctor, too, has often to contend against the unwillingness of the mother or nurse to carry out fully the directions given

Dr **Smith**, in closing the debate, said he had reference to the moist stage of eczema when he spoke of using dry dressings It is a mistake to suppose that the powder will confine the pus It will force its way through the dressing or lift up the crust He doubted if Dr Adams could shave some of the scalps he had seen He had treated sore nipples very successfully with dry dressings He related a case where the patient, a cook, was severely scalded by hot soup The application of dry dressings quickly relieved the patient, and in a short time he discharged the woman entirely cured with the exception of one or two places near the axilla

Dr **Hagner** said, in reference to the last case mentioned by Dr Smith, that he had been called to see her and had been compelled to poultice and remove one or two large scabs from the breast, and after the use of an ointment the woman was finally cured

Dr **Busey** asked Dr Smith if he sprinkled the powder over the entire surface or simply around the edges

Dr **Smith** replied that it was only necessary to put it where there was a moist surface

THE AMERICAN ACADEMY OF MEDICINE

Ninth Annual Session, held in New York City, October 28 and 29

(Concluded from page 525)

Thursday, October 29—Second Day

The Academy was called to order at ten o'clock

A resolution expressing the sympathy of the Academy with Dr H P Farnham, in his painful illness, was offered by Dr H O Marcy, and adopted

PRELIMINARY EDUCATION FOR MEDICAL STUDENTS

The following resolution was adopted

Resolved, That a committee of three be appointed by the President, to report at the next annual meeting, instructed to prepare a statement of the best preliminary education for medical students, and also a statement of the minimum attainments which medical schools should require of students before admitting them to the study of medicine

It was also resolved to appoint a committee of two whose duty it shall be to report the requirements for a preliminary education of the various medical colleges in the United States and in Canada

The following were elected

OFFICERS FOR THE ENSUING YEAR

President—Dr R Stansbury Sutton, of Pittsburg, Pa

Vice-Presidents—Drs Lewis P Bush, of Delaware, S J Jones, of Illinois, R L Sibbett, of Pennsylvania, and F H Gerish, of Maine

Secretary and *Treasurer*—Dr R J Dunglison, of Philadelphia, Pa

Assistant Secretary—Dr Charles McIntire, of Easton, Pa

Pittsburg was selected as the next place of meeting, time, the third Tuesday in September, 1886

DR. THOMAS J. TURNER, Medical Director U. S. N., read a paper on

MEDICAL EVIDENCE.

The *raison d'être* of the paper had its origin in the writer's duty in connection with the Naval Retiring Board. The positions of the medical members of the Board are that of an ordinary witness, that of an expert witness, that of a concurrent judge of both the facts and the law, but with the execution of the verdict the Board has no authority whatever. In the first instance the medical officer makes a physical diagnosis, in the second place he makes a rational diagnosis, based upon subjective phenomena, combining these, he arrived at a conclusion. On questions of science, skill, art, and the like, persons instructed on such subject-matters, known in ordinary language as experts, are permitted, from the necessities of the case, to give "matters of opinion" in evidence, and as to the necessity which permits the introduction of such opinions, each tribunal determines for itself at the time. Herein the expert differs from the ordinary witness who testifies as to "matters of fact." The boundary line where ordinary testimony ends and expert testimony begins is not always well defined.

As regards opinions on medical questions, any one, at present, may be permitted to testify, the question of the special amount of knowledge being left to the jurors to determine. It follows from this that there is no evidence which varies so immensely as so called expert evidence. It has been decided that a medical opinion may be received as evidence if it is based upon study without practice, or upon practice without study, and it has been ruled that it is not absolutely necessary that one should have studied or practiced medicine.

The opinions of medical men are admitted in courts, upon the condition of the human race thus: Is or was a certain person sick, upon the nature and cause of the disease, the cause of death, the cause and effect of an injury, the effect of medicine or of a particular treatment, the likelihood of recovery, the mental condition of the person, and upon the examination of the party whose condition is under inquiry.

It was the speaker's opinion that the term expert testimony was somewhat misleading, and he preferred the term "opinion evidence" as used by *Best* as preferable, for opinions may be admitted in evidence by those who could not be classed as experts. The test of the admissibility of opinion evidence seemed to the writer to be this: Has the expert witness any peculiar knowledge or experience not common to the world which renders his opinion, founded upon such knowledge or experience upon the subject-matter under inquiry, of value to the court in determining the truth of the matters at issue? The degree of credence given to opinion evidence should be founded upon the professional skill, the quickness of perception, the powers of discernment, the aptitude, the acquirements and the education, as well as the experience and observation of the expert in the matters upon which his special expert knowledge arises.

REPORT ON LAWS REGULATING THE PRACTICE OF MEDICINE IN THE UNITED STATES AND CANADA,

by RICHARD J. DUNGLISON, M. D., of Philadelphia, and HENRY O. MARCY, M. D., of Boston, was read by Dr. R. J. Dunglison.

He said that so little change has taken place within the last twelve months with reference to legislative restriction of the practice of medicine, that your committee might in a few brief sentences dismiss the subject with the statement of the actual work accomplished in this direction. The honest efforts of medical men and of others during the past year to accomplish creditable results in the States for the repression of quackery have been unabating, but in several cases, disappointment has been the only issue of their labor. Indiana and North Carolina are the only States in which any alteration in existing laws has been made. Your committee entered into correspondence with medical gentlemen in the different States with regard to the working of laws for the regulation of the practice of medicine, and their replies are submitted. The following is a synopsis:

From New York it was reported that the act of 1884 had not been effective in excluding from the profession grossly incompetent and uneducated men.

In Massachusetts there is no satisfactory law.

In Pennsylvania, the registration act is executed about as well as any law of the kind could be without an executive head. It has stopped the non graduated class from practicing.

From Michigan, it is reported that the present law is defective.

In Tennessee, there is no law regulating the practice of medicine.

In Ohio, the only law is one passed ten or fifteen years ago, requiring a diploma or a certificate from a chartered medical school. Several bills for regulating the practice of medicine have been proposed, but none have been adopted.

Wisconsin has adopted no law for the regulation of the practice of medicine.

Kentucky requires a diploma or a certificate from a State Examining Board. This law is working well.

Dakota last winter passed an act establishing a Territorial Board of Health, the function of which is to grant licenses to practice medicine and surgery in the Territory. There are, however, several difficulties in the satisfactory enforcement of this law.

Texas is practically without any law upon this subject.

In North Carolina, an act has recently been passed making it a misdemeanor punishable by fine or imprisonment, or both, to practice medicine in North Carolina without a license from a board of examiners elected by the State Medical Society. The results of this law have so far been satisfactory.

In New Jersey, the registration law has proven of little service.

Nebraska has a registration. While its results are not evident, yet it seems to be preparing the way for more effective action.

Iowa has no law regulating the practice of medicine.

Two years ago, Virginia passed a law establishing a State Board of Examiners This is working satisfactorily

Maine has no law on this subject In New Hampshire, the law regulating the practice of medicine has not accomplished very marked results

In Maryland, the law works very badly

In closing, Dr Dunglison said "From this sketch of medical legislation, the inference is fairly deducible that the legislation upon the subject of medical practice is not yet placed upon a sufficiently firm foundation to gratify the advocates of restrictive enactments, and that the obstacles to such healthful results are still operative, but not insurmountable"

DR BENJAMIN LEE, of Philadelphia, read a paper on

HEALTH OFFICERS ANCIENT AND MODERN

The important position assigned to hygiene and State medicine during the past decade is an evidence at once of the advanced stage of civilization and of the dense and rapidly increasing population It also indicates that long occupancy of the land by successive generations has at length overtaxed the regenerative and self purifying energies of the earth, and that extraordinary methods have become necessary

Reference was then made to the honors bestowed on the officers of public health in ancient Rome, and the high esteem in which they were held To this was largely attributed the excellent sanitary condition of that city

The second portion of the paper was occupied with a consideration of the organization of boards of health The first point made was that in selecting the material for boards of health, politics, in the bad American sense of the term, should be rigidly excluded Where it is possible to avoid it the members should not be elected by the people, especially is this the case in large cities

Secondly —Boards of health should be composed chiefly of physicians, but at least one member should be a man eminent among his fellows for prudence and judgment in trade and commerce, for doctors are, proverbially, bad business men

Thirdly —As it is desirable that there should be harmony of action and of sentiment between the municipal government and the board of health, there should be a representative of one on the other

Fourthly It is essential for the practical working of the Board that it shall employ a paid agent who shall devote as much time as is necessary to inspection and investigation of the sanitary condition of the locality, and carry into execution the orders of the Board

Finally, every member of the Board should receive a fair and even generous compensation for his labor

DR S N NELSON, of New York, read a paper on

MICRO-ORGANISMS AND THEIR RELATION TO DISEASE

Dr Nelson began by saying that the importance of the subject, already much discussed, was the only apology offered for presenting it That these minute organisms make up what they lack in size by the interest they are causing in the scientific world That great numbers of observers are at work on both Continents in the solution of the germ theory of disease Their history is related to that of spontaneous generation, to that of the fermentations, to the pathogeny and therapeutics of a great number of virulent and contagious affections, and in a more general manner to all the unknown, which, notwithstanding the efforts of modern science, still surrounds the origin of life and its preservation The bacteria belong to the vegetable kingdom and are the lowest of organisms, being merely cells of a globular, oblong or cylindrical form, reproducing themselves partly by spores and by transverse division The best authorities now adopt the simple classification into (a) bacilli, or the rod forms, and (b) micrococci, or the round forms The first observer who recognized them was Leuenhoeck, as early as 1675 Their study has advanced with the improvement of the microscope, until now many forms are only seen by the best lenses, aided by special condensors The more delicate and exact methods of the most recent observers with regard to their nature, show that there are many varieties of them, each of which has its own conditions of growth, and varies in its susceptibility to different temperatures and chemical reagents Apparent identity of form does not necessarily indicate identity of nature They may be cultivated in both solid and liquid nutrient media

The theory of a causal relation between bactria and diseased processes has recently received a wide acceptation In some diseases this relation is demonstrated, while in others it is presumed on the ground that bacteria are found in the blood and diseased products It is not only necessary that the germs should be isolated and grown in pure cultures, but by inoculation the disease should be produced in healthy men or animals with a reproduction of the bacteria Reference was then made to the various diseases that have been studied from this standpoint, and the present status of our knowledge was remarked concerning tuberculosis, cholera, variola, scarlatina, measles, diphtheria, erysipelas, etc Dr Nelson related some of his own experience in cultures of the micro organisms of many of these diseases, with which he has made many thousands experiments in the last five years, both at home and in Germany, under the supervision of Prof Koch in his laboratory in Berlin

DR ERNEST W CUSHING, of Boston, read some

OBSERVATIONS ON THE RELATION OF BACTERIA TO CERTAIN PUERPERAL INFLAMMATIONS

These observations were based on the results of examinations of the bodies of such women as died from these maladies at the general hospital at Vienna last spring He called attention to the great difference between the customs and rules governing the obstetric assistants and students in Berlin and in Vienna In the former city, every precaution is taken to avoid not only direct infection, but also any possible carrying of germs in the hair or clothing, as if bacteria were freely present in the air In Vienna, although the possibility of so finding them is admitted in theory, yet in practice the assistants and students are allowed to be present at autopsies Obstetric operations and laparotomies are performed before the whole class, without spray, and the chief assistants give operative courses on the cadaver every afternoon, relying for safety on washing, bathing, and change of clothing   Practically, sepsis arising in the hospital is very rare, and the results obtained by avoiding direct infection through the fingers and instruments, were regarded by the speaker as an argument in favor of the view that puerperal fever is not an entity, the poison of which is carried about in the air and enters the system through the lungs, etc , but that such fevers are the result of the invasion and multiplication of bacteria, arising from infection of the uterus or abraded vagina, as a rule directly from hands, instruments or application

Discussing the results obtained by the examinations above mentioned, the reader stated that the most frequent cause of infection was the strepto coccus, the next the straphylo coccus, with which is frequently associated the bacillus pyogenes fœtibus   The first occurs in chains not distinguishable from those of erysipelas, the cocci usually lying in pairs, each pair representing a link   The staphylo cocci occur in bunches like those of grapes   One or the other of the above were found in all acute cases examined, and were present in the uterine or iliac veins   In pelvic abscesses they were found in the lungs and joints, and in fact wherever metastatic abscesses occurred   Microscopic preparations of the above and three specimen cases were described   Finally puerperal inflammations were compared to infected wounds   The powers of the system to resist, fence out and kill the invading bacteria when the latter are not continually reinforced, were emphasized, and an active hopefulness was advised in regard to treatment, which, to be successful, should be analagous to that of surgical wounds, *i e*, prompt removal of decomposing matter, evacuation of pus, cleansing and disinfective douches and drainage

Dr R Stansbury Sutton said that while there was no question as to the success achieved by the use of antiseptics in general surgery, yet in abdominal surgery the best results so far had been obtained by strict attention to cleanliness, without the use of any antiseptic agencies   He agreed with Dr Cushing that when the poison entered the abdominal cavity in laparotomy, or into the vagina or uterus in puerperal cases, the germs are not carried by the atmosphere, but by the hands, the forceps, ligature, or instruments   As far as abdominal surgery was concerned, he thought that all chemical agents could be discarded, but cleanliness should not be lost sight of   He then referred to the injurious effects which had at times resulted from the absorption of such agents through the peritoneum

Dr Henry O Marcy related a case bearing on the introduction of antiseptics into the peritoneal cavity   It was that of a child four years of age, whose abdomen was filled with pus, in which the streptococcus was found   The pus was evacuated and the peritoneal cavity thoroughly washed out with bichloride of mercury solution   The patient recovered without a bad symptom

Dr Edward Jackson, of Philadelphia, read a paper on

MEDICAL LICENSES AND MEDICAL HONORS

A comparison was made between the requirements of the medical colleges of this country when first organized and the requirements of to day, and gradual lowering of the standard with the corresponding decrease in the honor conferred, was noted   While the population had increased twenty times, the number of graduates had increased five hundred times   Part of this increase is due to the fact that men who formerly practiced without a degree, now attend colleges and receive the degree

In 1881 the medical diploma was put to a new use, and became a license to practice   The inefficiency of the registry law, as well as the lessened honor which attached to the medical degree, was shown by the fact that in fifteen hundred registrations only forty-eight were destitute of the doctor's degree, and these belonged to the poorest order of irregular practitioners

The speaker thought it doubtful if any system of State license to purchase a certain calling should be looked on with favor   If adopted, it must be removed from all possibility of lowering competition, and surrounded by every guarantee of honest enforcement which disinterested examiners and full publicity can give

A paper entitled *The Physician and his Patient*, by Dr J D Kelly, of Utica, N Y, and one by Dr Lewis P Bush, of Wilmington, Del, on *The Physicians of Delaware in the Eighteenth Century*, were read by title

The President-elect was then introduced, and made a brief speech

The Academy then adjourned

MASSACHUSETTS MEDICAL SOCIETY—SUFFOLK DISTRICT

SECTION FOR CLINICAL MEDICINE, PATHOLOGY AND HYGIENE

Stated Meeting, October 14, 1885

The Chairman, R P Edes, M D,
in the Chair

Dr Morton Prince, stated that the title of his paper at the last meeting of the section should be amended so as to read "Friedreich's Disease"

ELECTION OF CHAIRMAN

The chairman announced that the first business to come before the section was the election of chairman for the ensuing year   A ballot was accordingly taken which resulted in the election of Dr F I Knight as Chairman of the Section

Dr Philip Coombs Knapp exhibited a patient with

PSEUDO HYPERTROPHIC MUSCULAR PARALYSIS

The patient, a boy of 6, was born in Boston, of German parentage   He was sent to the Boston City Hospital September 21st, by Dr Broughton, of Jamaica Plain, from whom, and from the boy's parents the following history was obtained

Family History   A full history of his father's family was not obtained; on his mother's side two cases of phthisis were reported, but no evidence of any neurotic history could be obtained. His parents are healthy. He himself is the youngest of eight children, the rest of whom are well. Four other children died in infancy of "water on the brain," one also having cholera infantum. The patient was a very feeble child, too weak to nurse, and had to be brought up on the bottle. During his first year he had diarrhœa much of the time, and seemed very delicate. When he was a year old, he had whooping-cough, attended with severe and frequent convulsions; he had convulsions at intervals for two months, once having seven in one night. After that he recovered, grew stronger, and has seemed healthy ever since, except for his present trouble, and for an illness of two days when he was 2 years old, "which seemed like water on the brain." When he began to walk, it was noticed that his left leg gave out at times, and he would sometimes fall. His legs were very fat, much fatter proportionally than his thighs, but at present his mother thinks the contrast is not so marked.

About a year ago, without any signs of illness, his parents noticed that he had more difficulty in walking. The trouble came on very slowly and gradually. He could not walk as well, and when out with the other children it was noticed that he could not run, and that a very slight push would knock him down. If he walked much he had a tired feeling in his legs, but he never had any pains in them, nor any peculiar sensations. The family for some time have laughed at him for "sticking his belly out" as he walks and stands. He has not been able to go up stairs well; when he does so, he pulls himself by the banisters or takes hold of his knees, having much difficulty in getting up. He puts the left foot first, they say, in going up stairs, and the right in coming down, the right leg seeming weaker. He never has headache, and sleeps well nights. He is quick witted, good natured and always happy; he answers questions readily, without any impairment of articulation, and seems more than ordinarily intelligent. He has not yet, been to school, partly from his difficulty in locomotion, and partly for fear that the larger boys will knock him down and hurt him. He has never had any serious cough, nor any dyspnœa or palpitation. He has a good appetite, eats everything, and has no trouble from indigestion; his bowels are regular. He has no difficulty with micturition.

Present Condition.—The child is of medium size, fairly developed, not very well nourished. The skin is pale and translucent, the subcutaneous veins are quite apparent. Their is no erruption or marbling of the skin. The head is rather large and square. The pupils are of medium size and react well to light; the eyes were examined by Dr. Wadsworth and the optic discs were pronounced normal. The eyes, face lips and tongue move naturally. The tongue was clean. Examination of the chest was negative. There was no impairment of tactile sensation. There were no signs of vaso motar disturbance in the skin, which showed no special difference of temperature to the hand in various parts. There was no ataxia in the movements of the hands. The patellar reflex was absent and there was no ankle clonus; plantar, abdominal, and epigastric reflexes present. No tenderness over the spine or nerve trunks.

There was no very great hypertrophy of any group of muscles. The facial muscles showed no marked atrophy or enlargement, and he could move them without difficulty; the expression of the face, however, was very peculiar, the eyebrows were elevated, the eyes staring and prominent, the mouth often a little open, and the lines of the face were not marked, and there was but little play of expression. His father, however, had noticed no change in this respect. The muscular development of the upper part of the body was rather poor. The arms were small, but there was no atrophy or hypertrophy that would strike the eye. The latissimus dorsi and pectorals were poorly developed, yet corresponded fairly to the other muscles. The infra-spinatus muscle filled the infra spinous fossa completely but did not feel hard. The deltoid felt rather firmer than some of the other muscles, the triceps was of good size and decidedly harder than the biceps; the muscles of the fore arm were also firm. There was no atrophy of the thenar muscles. The glutei were unduly prominent. The thighs were small, the quadriceps felt flabby. The calves were large and very hard and firm. Although the calves were not unduly enlarged for a healthy boy of his years, they were much enlarged in proportion to the other muscles. Circumference of the thigh in the largest part 10 inches, of the calves 8⅝ inches.

The child stands with his feet well apart, his shoulders back, his abdomen very prominent, his arms semi flexed, abducted, and carried a little backward. His scapulæ stand out in a wing like fashion from the chest wall. A plumb-line dropped from the spinous processes between the scapulæ, clears the sacrum, but not the buttocks as he stands erect. His gait is decidedly waddling, especially when he runs. His grasp is not very strong, but it is fair for his years. His arms show no special loss of strength. When he stoops over to pick up anything, he has much difficulty in straightening up again, and usually helps himself by putting his hands on his knees and throwing his body back, although he does not climb up his thighs much, if any. When he is put on his back and told to get up, he first rolls over on his belly, then he lifts himself up on his hands, straightens his legs, walks up to his hands, then he gets hold of his knees, pushes himself up, and throws his body back in precisely the manner described by Gowers. He cannot bend his knees and rise up again, and, if he stands on one leg and a forcible attempt be made to bend the knee, he goes down in a heap. He also goes down suddenly when he attempts to sit. His favorite way of going up stairs is to creep up on his hands and knees; if told to walk up, he prefers to get hold of the banisters and pull himself along. If made to go up without taking hold of anything, he has very great difficulty, even with stairs of a very slight rise, and sometimes he requires help. He always puts his left foot up first and pushes himself up by his knees. If told to put the right foot first he has much more difficulty, and often fails entirely to get up He can rise up on his toes very well, even on one foot, and he can bring his heels squarely to the ground Dorsal flexion of the foot is not quite so complete as normal, but it is impossible to say whether it is due to a weakness of the flexor groups or to a slight contraction of the gastrocnemii

An electrical examination was made by the induced current, but it caused so much pain that a complete and careful examination was not made The deltoid, biceps and extensors of the arm react feebly to a tolerably strong current The gastrocnemii and glutei react to a painful current, the full strength of a Fleming and Talbot battery, freshly filled The tibialis anticus react very little, if at all, but the pain of the application made the child so restless that it was impossible to observe the reaction carefully The quadriceps showed absolutely no reaction to the strongest current

The boy has been given cod liver oil and syrup of the iodide of iron, and directed to come to the out-patient department three times a week to have faradism applied

Dr J J Putnam remarked that often in the earlier stages of this disease the muscles of the upper extremity appear to be enlarged, and firmer than usual, sometimes seeming to be actually hypertrophied The deltoid frequently presents the appearence of hypertrophy at this stage, and the muscles of facial expression are much more prominent than usual The facial expression sometimes undergoes a marked change from the change in volume of the affected muscles The gastrocnemii are often not weakened at first, but are actually stronger than normal The disease seems to consist at first in a variation of the developmental force and direction, rather than in an actual degenerative process located in the spinal cord

Dr Gowers has made many examinations of the nervous centres in this disease, but has not always succeeded in detecting pathological changes in these structures In one case he discovered a portion of muscular tissue within the spinal canal

Dr C F Folsom read an elaborate and very interesting paper upon

GENERAL PARALYSIS IN THE PRODROMAL PERIOD

The patient was a clergyman who had always been well until recently, when he is said to have been affected with intermittent fever for which he is still taking quinine It has been noticed that within the past year his disposition and character have undergone an unexplainable change, and that his sermons are quite rapidly deteriorating in excellence of thought, as well as in excellence of diction and purity of composition The patient is himself aware of a change in this direction, but considers it due to a lack of energy upon his part, claiming that he might now produce equally good discourses if he would but make the necessary effort He is, however, very well satisfied with his present sermons, but often preaches his old ones, as he considers them "too good to be lost" He is desirous of extending his usefulness, and has at times "exchanged" with other clergymen On a recent occasion he preached in a strange church and made a very favorable impression The congregation was accustomed to but one service on Sunday, but this clergyman thought that his sermons were so good, that he announced a second service, which he laughingly states was attended by *one* person He is not at all disturbed by any embarrassment of circumstances, but seems quite satisfied with whatever occurs He wrote to Dr Folsom making an appointment, which he found he could not keep, and sent a timely note asking for a change of appointment to some more convenient time Upon being asked to write a page of ordinary paper he was quite at a loss what to say, when he was asked to write the text of his sermon the day before, he was utterly unable to recall it He was equally unable to remember a clause or idea from the sermon, or anything connected with the services of that day Upon removing his garments for the purpose of a physical examination, it was observed that he wore two starched shirts, one outside the other When asked why he dressed thus, he said that the outer one was the clean one of the day before, and he put it on in order to prevent it from becoming crushed by being placed in his valise When asked why he did not lay the soiled shirt into the valise when he took the clean one out of it, he seemed to think that this would be a good idea, but he himself had not been able to think of any way, except to wear the one shirt outside the other He several times made the remark that his urine was scanty owing to some disease of the liver When it was suggested that the kidneys were the organs by which the urine was secreted, he seemed to be aware of his mistake and was amused that he should have made such an error He complains of ringing in the ears and some degree of pain in the head which he attributes to the quinine prescribed for his "malaria"

His handwriting has changed to a marked degree within two or three years, and now presents the tabetic character quite distinctly His present photograph by itself is not remarkable in any way, but compared with those of three and five years ago shows extensive changes in the expression, the facial outlines having become much less striking to atrophy of the muscular structures of the face, by which the countenance is changing in the direction of imbecility Speech is still fairly good, though when fatigued or confused, the utterance becomes very slow, and the patient is often unable to pronounce words of several syllables without repeated efforts Although a clock was within plain view, the patient would have missed his railway train had he not been reminded that it was time to go, upon which he made his arrangements in the most exemplary manner and left for his home After a period of complete rest, he was again seen, when the symptoms of nervous derangement had so far disappeared that the most searching examination was necessary to detect the signs of any degeneration of the nervous structures Only when the patient became somewhat fatigued did the signs of paralysis become evident

These early and faintly marked symptoms are more carefully recorded in this case, and special attention is directed to them from the fact that they represent to some degree the "prodromal stage" of general paralysis, a period in the history of the disease, which the physician is seldom able to observe, as the symptoms at this time do not usually attract the attention of the patient or his friends, and medical aid is first summoned at a much more advanced stage of the malady, when cerebral changes have already occurred, and the case is hopelessly incurable If anything in the way of treatment can be of any avail it must be employed in the earliest stages of the disease The diagnosis of general paralysis once established, our prognosis in all such cases is at present invariably and unalterably hopeless If any benefit is ever to be gained in this disease from therapeutic measures, it must come from treatment of its earliest stages before cerebral degeneration has occurred

DR JELLY stated that he could add very little to the complete description of this forlorn disease which had been given by Dr Folsom The early recognition of the disease, and the study of the family history and individual traits are of the utmost importance This was forcibly illustrated in a case coming under the speakers personal observation in which a wealthy and influential merchant had for two years been noticed to become gradually more and more erratic in business, and to make foolish and extravagant errors, and unaccountable mistakes He was adjudged to be in the commencing stage of general paralysis, the stage of insane grandeur, and the friends were advised to remove him from business and to secure for him repose and perfect relaxation

Before the nature and extent of the disease was appreciated by the patient's relatives, however, his entire fortune had been wasted, and when he was finally placed under medical care, his family were already in the depths of poverty The patient was not benefited by treatment, but the disease rapidly advanced from the exaltation of the first stage to a condition of permanent and hopeless dementia

DR J J PUTNAM said that while his own experience brings him in contact with comparatively few patients with general paralysis, yet he has been struck by the surprisingly large number of cases of this disease which have become known to him There is no doubt that many cases exist which are entirely unsuspected until some painful or unsuspected event directs special attention to the individual, when the disease is at once distinctly recognizable The statement of Dr Folsom, that in many true cases of the disease there is astonishingly little which can be discovered in the way of positive symptoms, is unfortunately true In many cases absolutely nothing can be detected, upon which to base a sound diagnosis, and doubtless, oftentimes normal traits of individual character are ranked as features of the disease

DR PUTNAM asked with how great a degree of certainty can many cases be diagnosticated?

DR FOLSOM replied that in many patients the symptoms of this grave disease are very obscure They may consist of three elements diminution of muscular power, diminution of mental vigor, and derangement of the vaso-motor functions in the slightest degree When notable changes in character and disposition occur, between the ages of forty and fifty, after the adult character of the individual may be supposed to have been firmly established, the indications are strongly in favor of general paralysis Symptoms often entirely disappear from observation for a period of many months, but again recur after some trivial cause, like loss of sleep or overwork A sudden change in character and disposition in a vigorous man, without other explanation, is almost invariably indicative of general paralysis

DR JELLY asked if the prognosis is always necessarily so bad as has been supposed?

DR FOLSOM replied that he had never seen a cure in any case There is no known record of cure in this disease The prognosis is entirely hopeless The therapeutics of this disease offers no encouragement at the present time The whole question of treatment is in a most unsettled and unsatisfactory condition The subject is in about the same condition as was that of pulmonary tuberculosis some fifty years ago Cases generally come under the observation of the physician at too late a period, when organic changes have already occurred in the brain, and degeneration of the nervous and muscular structures have already taken place At this stage no known method of treatment has ever been of the slightest avail

(*To be concluded*)

DOMESTIC CORRESPONDENCE

NEW YORK LETTER

(FROM OUR OWN CORRESPONDENT)

Surgical Practice in Bellevue Hospital—Wiring the Fractured Patella—A New Serre Naud—Charity Hospital Training School for Nurses—The Anti vaccination League—Cremation—A Circulating Library for the Blind

At the meeting of the Academy of Medicine, on October 15, the paper of the evening, which was a very satisfactory one, was by Dr Stephen Smith, on "The Comparative Results of Surgical Practice in Bellevue Hospital" He thought that there was perhaps no better place in which to test the progress of practical and operative surgery than the wards of this old institution, since it had within its walls and its immediate environments all the conditions that in modern times are regarded as unhealthful and unsanitary It was built, he said, between the years 1811 and 1816, on the made lands of East River, without drainage or adequate sewerage, and without regard to ventilation During nearly three quarters of a century the sluggish tides have ebbed and flowed through the sodden soil of its foundation, depositing far more filth than they have removed, and since its occupation it has been used as a prison and an almshouse, as well as a hospital Moreover, its wards have, from time to time, been crowded with patients suffering from all forms of contagious and infectious diseases, and it has been the common receptacle of typhus and typhoid fevers, small pox, puerperal fever, cholera, and yellow fever

Although many changes have been made in its interior, yet the great and most serious defects of location and construction have remained unaltered The surgeons of Bellevue, as Dr Smith rightly said, have always ranked among the best in the city, and as much of their practice in hospital has been public and clinical, it must be assumed that they have endeavored to the best of their ability to illustrate to their classes the highest type and best results of the science and art of surgery of their day And yet the practice of surgery in Bellevue Hospital has within the past few years undergone so complete a revolution that one of the older surgeons would scarcely realize that he was in the same hospital where he had practiced a decade ago "He would see with horror operations fearlessly performed that he had formerly regarded as without the pale of legitimate surgery He would witness procedures in the after treatment of operations which would seem to him to be fantastic, and even ludicrous His astonishment would be extreme on finding that the first week passed without fever, and that no change in the dressings had been made But perhaps the most remarkable feature of modern practice would be the rapid convalescence, and final complete recovery, without complication or exhaustion, of ordinary operations, which formerly gave so much trouble and anxiety"

Before the use of anæsthetics, the most important general principle governing the operator was celerity, but now, Dr Smith asserted, the one thought and purpose that occupies the mind of the surgeon is recovery without suppuration, and to this end all his preparations are made, and the entire procedure subordinated Having described the details by which this is accomplished in operations in general, he passed in review a number of special methods of treatment and operations, such as the treatment of compound fractures, amputations, excisions of the larger joints, the ligation of large arteries, and the treatment of cold abscesses He then went on to say that perhaps the most marked illustration of the great improvement in operative surgery in Bellevue may be found in the unvarying success which attends the treatment of simple fracture of the patella by wiring together the fragments "It was eminently fitting," said Dr Smith, "that this operation, so novel and startling as to be received with almost universal ridicule by older surgeons, should have first been proposed by the great apostle of antiseptic surgery By proposing and successfully executing this operation he expressed his faith in his teachings in form more emphatic and convincing than language could This procedure does, indeed, embody the very spirit and genius of the surgery of to day, viz boldness to audacity in the conception of an operation, and conservatism the most absolute in the method and means employed in executing it And yet this operation is now accepted as legitimate in Bellevue, and is of almost weekly occurrence in one or the other of its surgical divisions And no operation, so inherently dangerous when performed according to old methods, has ever proved more successful It has now been performed in more than a score of cases without an unfavorable result"

The paper concluded in the following words "In reviewing the surgical practice of Bellevue, it is not difficult to determine the essential feature of the present methods as compared with those of the past Cleanliness is the one great object sought to be attained in all operations Whatever may be the final conclusion of scientific students as to the cause of putrefaction in wounds, practically it is determined that the surgeon may, with the most absolute certainty, protect an ordinary open wound from suppuration To effect this object, he finds that he has simply to secure perfect cleanliness of the wound The agents now relied upon and found efficient are 1 Soap and water to external parts 2 Carbolic solutions for instruments 3 Bichloride solutions to all surfaces and tissues 4 Iodoform for external dressings We may summarize the conditions regarded as essential to success as follows *A clean operator, clean assistants, clean instruments, clean dressings*"

At the last meeting of the New York County Medical Association, held October 19, the principal paper of the evening, by Prof Frederic S Dennis, of Bellevue, was on the operation of opening the joint and wiring the fragments of bone together in fracture of the patella referred to in Dr Smith's paper At the outset he said that, while Sir Joseph Lister had recently revived this procedure under conditions which ensured for it a most brilliant future, it was not to be forgotten that it was of American origin, having originally been performed by Barton, of Philadelphia, and in this connection he paid a fitting tribute to the genius and skill of American surgeons in general Having stated that he desired in the communication to present all the arguments which had been adduced both for and against the operation in question, he went on to say that there were at the present day two classes of surgeons who represent professional opinion The first considered the operation perfectly justifiable, believing that when it was performed with proper antiseptic precautions, it was unattended with danger It was true that up to 1883, out of some forty-nine cases, there were two deaths, while in six instances it had been followed by suppuration and anchylosis, but since then the results have been materially better Out of more than fifty cases reported, there had been no death, and in only three, one of which was a compound fracture, had there been suppuration

The second class of surgeons referred to held that the operation was unjustifiable on account of the great risk involved in opening the joint, and claimed that equally good results could be obtained by the older methods of treatment Dr Dennis was fully convinced himself that the modern antiseptic operation was in every way preferable, and could, as a rule, offer the results of osseous union and a perfect joint, which every surgeon knew the difficulty of obtaining by any of the former methods Under proper restrictions, he believes it to be an ideal operation

One great reason why bony union was so rare when these methods were employed was, he thought, because the layer of tissues in front of the patella almost invariably gets in between the fragments, and he mentioned the following three arguments in favor of the newer and bolder treatment *First* The absence of danger to life and limb *Second* The superior results as regards the functions of the limb and the joint *Third* The greater rapidity of repair He then proceeded to adduce a considerable amount of clinical evidence in support of his assertions, among which he mentioned a case of compound fracture which had been under his own care The patient fell from a scaffold, fracturing the patella transversely, and the joint was found to be wide open and filled with blood Yet in a few weeks the man was walking about again with perfect ease, and at present the limb was just as good as ever, since he was able to dance, to climb a ladder, and to walk ten or fifteen miles In speaking of the rapidity of repair, Dr Dennis related another case of his own, in which the patient died six days after the operation from delirium tremens and Bright's disease, and yet, notwithstanding the short time that had elapsed, very firm bony union was found to have already occurred There was no callus thrown out, and the reparative process was altogether analogous to primary union in the soft parts The entirely unique specimen from this case was also presented The remarkable gain in time resulting from this operation is certainly a very important object, not only to the day laborer, but to the professional and business man

It was true, he said, that the Academy of Medicine in Ireland and the Société de Chirurgie had declared against the new operation, but he had no doubt whatever that the tide of professional opinion would soon turn in its favor The circumstances had been very much the same as regards abdominal section in surgery, in regard to which so complete a revolution of sentiment had occurred It had been claimed that the knee joint would be liable to the formation of osteophytes after this operation, but this was merely a fanciful objection Another objection put forth was that ramifying osteitis was likely to occur, but he had never seen any such result

Dr Dennis devoted the latter part of his paper to a discussion of the technique of the operation, and finally announced a number of conclusions, among which were the following

1 In compound fractures of the patella there is not the slightest doubt of the propriety of the operation

2 In recent and old fractures, under ordinary circumstances, and with the patient's consent, it is wholly justifiable

3 In debilitated patients, and those suffering from organic diseases, the operation should not be performed

4 It is not an operation which can be indiscriminately performed It should never be undertaken by the inexperienced, or by any one who has not the most perfect faith in the efficacy of antiseptic surgery

5 Success depends on the most strict observance of the minutest details of antiseptic procedure

6 Its results are far more satisfactory than those attending any other method of treatment

At the end of the paper, Dr Dennis presented a number of patients who had been cured or were in process of treatment, and among them was the case of compound fracture which he had narrated, as well as a similar one treated by Dr Fowler, of Brooklyn, which was the first of its kind in this country, and which, he said, marked an era in the progress of American surgery

Among those who took part in the discussion were Drs Fowler and Burge, of Brooklyn, and the latter remarked that up to this evening he thought he had brought the treatment of fracture of the patella up to a state of great perfection, but now he felt like a junior student He believed that he had actually learned more at this meeting than he could have done by a three months' sojourn in Europe

Afterwards Dr H M Biggs, of the Carnegie Laboratory, gave a demonstration of cultures of the micro organisms of osteo-myelitis, and Dr F Forné, a surgeon in the French Navy who is now stationed on one of the men of-war in New York harbor, presented a new instrument, a true *serre naud*, for tightening a knot continuously, which Dr Gouley pronounced the best device for the purpose which had ever been invented, believing that it would prove of especial value in ovariotomy

The ninth annual commencement of the training school for nurses of the Charity and Maternity Hospital, on Blackwell's Island, was held October 29th, in the amphitheatre of the Carnegie Laboratory There were fourteen graduates, and addresses were made by the Rev Dr Edward McGlynn, of St Stephen's Roman Catholic Church, ex-Mayor Wm H Wickham, and Dr F N Otis, of the visiting surgical staff of Charity Hospital The report of the school was read by Dr L L Seaman, Chief of Staff, who stated that since its organization, in 1875, it has had upon its roll 267 students, of whom 151 have been graduated At the conclusion of his report he said "I am proud to say among the nurses now may be found many ladies of culture and refinement, and the skill of the physician has been supplemented by the skill of the educated nurse The care and sympathy received by the patients promoted their recovery, while the presence among them of the pupils of the school so improved the moral tone of the institution that the cells for punishment were no longer necessary, and were removed The death-rate of the Hospital has steadily diminished since the introduction of the training school, as shown by the statistics of the past ten years It is now nearly sixty per cent less than before the establishment of the school, and while other causes have contributed to diminish the mortality, none has exercised so great an influence as the increased efficiency in nursing, due to the careful training of intelligent nurses" In the evening the ladies of the graduating class had a festive dinner at Charity Hospital

An adjourned meeting of the "Anti-Vaccination League" was held October 26th, at the house of Dr R A Gunn, the late Dean of the notorious exploded United States Eclectic Medical College, at which there were gathered at least a score of persons The illustrious Mr Henry Bergh presided, and delivered a harangue, in which he explained that the purpose of the meeting was to form a definite organization, to be duly incorporated under the State laws Under such an organization, he thought, could the public be fully aroused to the frightful evils of vaccination as in no other way Dr Gunn also made an address, in which he stated that members of the League held themselves in readiness to prove the fallacy of the theory of vaccination to the satisfaction of the public whenever its advocates or members of the Health Board would discuss it in open debate, and a committee was appointed to draw up articles of incorporation for what is to be known as the "American Anti-Vaccination Society" With the lessons of the Montreal epidemic staring it in the face, the public, for whose welfare these noble gentlemen are so solicitous, is hardly likely to flock to the standard of the new society in overwhelming numbers It is certainly a bad time to begin an enterprise of this kind at present

Dr John T Nagle, Deputy Register of Records of the Health Department, has given orders to the clerks having charge of the issuing of burial permits not to grant any permits for the removal of bodies from this city to the new Mount Olivet Crematory at Fresh Pond, Long Island, for cremation The order is based on the fact that the present Sanitary Code makes no provision for the cremation of human bodies, and that this is in reality a violation of the *Code* The authorities of the crematory will therefore be obliged to seek legal assistance in rescuing them from the unexpected dilemma in which they are placed

A very laudable enterprise has just been successfully inaugurated in the opening of a free circulating library for the blind There are said to be over a thousand blind persons in this city, and as the purchase of raised letter books is necessarily expensive, the library will be an incalculable blessing to many of them who have not the means to buy such works It is the first project of the kind ever undertaken in this country, and voluntary subscriptions are entirely relied upon for its support P B P

REDUCTION OF TEMPERATURE BY ICE-BAGS

To the Editor of the Journal

Sir —Stephan, of St Petersburg (see Journal September 26, 1885), is of opinion that the temperature in fever may be lowered by the application of ice bags over the super-clavicular region This effect is produced by bringing the cold in contact with the large superficial veins of the neck I have noticed that in some cases of pneumonia a sensation of intense heat is one of the most trying sensations from which the patient suffers In two of my cases much relief was afforded by the continuous application of the ice bag to the occipito-cervical region One of the patients told me "it was the only comfort he had" F A Burrall, M D

STATE MEDICINE

PROVISION FOR THE INSANE IN TENNESSEE

During the last two years, Tennessee has been actively improving the accommodations for her insane The hospital at Nashville, under the care of the distinguished alienist, Dr John H Callender, has been overcrowded for several years A new asylum at Lyon's View, near Knoxville, in East Tennessee, is nearly completed, and is expected to be open for patients in December next The site is well selected, and the buildings have been constructed under the direction of Dr Michael Campbell, who has recently been elected Superintendent of the Institution Dr Campbell was with Dr Callender in the hospital at Nashville two years, and is well qualified to fill the place of Superintendent We learn from a recent copy of the *Nashville American*, that Dr C C Fite, of that city, has accepted the appointment of Assistant Superintendent in the new asylum at Lyon's View Dr Fite is not only well and favorably known to the profession in Tennessee, but throughout the Mississippi Valley, and will discharge the duties of his new position with ability and fidelity The State has also made an appropriation for another asylum in West Tennessee, and a Commission is now engaged in selecting the most appropriate location

HEALTH OF MICHIGAN FOR OCTOBER, 1885

Reports to the State Board of Health, at Lansing, by regular observers in different parts of the State, show that, for the month of October, 1885, compared with the preceding month, diphtheria had increased, and that diarrhœa, cholera morbus, dysentery and cholera infantum had decreased in prevalence Compared with the average for the month of October in the seven years from 1879–1885, remittent fever, intermittent fever, typho-malarial fever, diarrhœa, consumption of the lungs, typhoid fever, bronchitis, dysentery, and cholera morbus, were less prevalent in October, 1885

For the month of October, 1885, compared with the average of corresponding months for the seven years 1879–1885, the temperature was lower, the absolute humidity was less, the relative humidity was much more, and the day and the night ozone were more Including reports from regular observers and others, diphtheria was reported in fifty nine places within the State during the month, and measles in three places

ASSOCIATION ITEMS

INFORMATION OF IMPORTANCE TO ALL MEMBERS OF THE AMERICAN MEDICAL ASSOCIATION

Membership —Every one who attends an annual meeting of the Association as a delegate pays at that time five dollars, and thenceforward becomes a Permanent Member He continues as such as long as he remains in good standing in the body from which he was originally sent as a delegate As a Permanent Member, he must pay *Five Dollars Annually*, when notified by the Treasurer, whether he attends the meetings of the Association or not Payment of annual dues entitles him to receive the weekly Journal of the Association for one year

Members by Application are such as have not become Permanent Members in the manner above indicated, but apply to the Treasurer for membership, forwarding at the same time to him five dollars and the certificate of the President and Secretary of their State or local society, that they are in good standing in such society They pay five dollars annually thereafter, when notified by the Treasurer Members by application can join the Association at any time, and they receive regularly the weekly Journal

When Dues are Payable —The annual dues from Permanent Members are payable to the Treasurer at the time of the annual meeting of the Association, or immediately thereafter The payment entitles the member to receive the Journal for one year from the following July Payment for 1885, for example, entitles the member to the Journal from July, 1885, to June, 1886, inclusive

As some of the members have not yet forwarded *to the Treasurer their dues for 1885, they are urgently* requested to do so at an early day Having entered upon another year of membership, they are morally and legally responsible to the Association for the payment of their annual dues, having already received for three months of the new year—1885—the Journal of the Association

Subscriptions to the Journal, from those who are not members of the Association, should be forwarded to the office of publication, 65 Randolph Street, Chicago, and not to the Treasurer, but *all payments of annual dues must be forwarded to the Treasurer, Lock Box 1274, Philadelphia*

Deaths —When a member of the Association, who is in regular receipt of the Journal, dies, his family or other representatives are requested to inform the Treasurer at once of the fact

Payment of Dues for Previous Years —As a few members of the Association are still in arrears for payment of dues for 1883 and 1884, they are requested to forward at once to the Treasurer the amounts for which they are indebted to the Association

Transactions of the Association —These annual volumes, thirty-three in number, to 1882 inclusive, may still be obtained, with few exceptions, from the Treasurer, at reduced prices The Index to these volumes will be forwarded on receipt of *One Dollar* An opportunity is thus afforded to complete sets of these valuable publications, or to obtain important papers and works which are daily becoming scarce

Richard J Dunglison, M D , *Treasurer*
Lock Box 1274, Philadelphia, Pa

MISCELLANEOUS

American Public Health Association —Arrangements have been made with the Baltimore & Ohio R R to carry delegates and members of this Association, their families, and all others desiring to attend the annual meeting of the American Public Health Association, to be held at Washington, D C , commencing December 8th, 1885

In view of the fact that public interest, at the present time, is centering in epidemics, it is especially urged that members of different Boards of Health take part in this meeting, either in a body or by sending delegates, as it promises to be the largest and most interesting meeting of the kind ever held in this country It is, perhaps, unnecessary to call your attention to the importance of attendance, when taking into consideration the fact that the coming season gives promise of being one of epidemics, and that it is necessary "in time of peace to prepare for war," and in the discussion of preventive measures, by those who have spent years in their study and practical workings, reach in the shortest time the best methods

Delegates and others desiring to attend the meeting, paying the limited fare ($17 00), via the Baltimore & Ohio lines, will be returned at one third the limited fare ($5 85), making a rate of $22 85 Chicago to Washington and return Certificates for the return tickets will be signed by Irving A Watson, Secretary, at Washington

It is hoped that all will avail themselves of the above low rates to attend the meeting

Those who contemplate going will advise T H Dearborn, General Northwestern Passenger Agent Baltimore & Ohio Railroad, 83 Clark Street, Chicago, who will assign them such sleeping car accommodations as they may desire State date of leaving Chicago

---

William Benjamin Carpenter, LL D , F R S, the eminent English physiologist, died a few days ago from the effects of burns caused by the upsetting of a lamp while he was taking a vapor bath for rheumatism He was born in 1812 He was graduated in 1839 from the medical school in the University of Edinburg, after having passed through University College, London Prior to 1839 he published a work "On the Unity of Function in Organized Beings," and subsequently a number of other works on physiology and the use of the microscope Dr Carpenter at one time was Professor of Medical Jurisprudence in University College, London

HYDROBROMIC ETHER OR BROMIDE OF ETHYL AS AN ANÆSTHETIC

BY LAURENCE TURNBULL, M D, PH G,
OF PHILADELPHIA

The hydrobromic ether or bromide of ethyl was discovered by Serullas in 1827, but received no special attention until Dr Thomas Nunnelly, of Leeds, made some experiments with it on animals in 1849 Dr Nunnelly brought the subject again before the profession, by a paper read at the meeting of the British Medical Association in 1865, in which, in conjunction with another anæsthetic, he says he had employed the one or the other in all the principal operations at the Leed's General Eye and Ear Infirmary This was at the time when chloroform held such complete sway in England, that no importance was attached to Nunnelly's experience or experiments, and he had no one to follow him in using it, and we hear no more of it until 1876, when some experiments were made with it in France, by Rabuteau, on the lower animals, but evidently without a knowledge of the fact that this had been done previously in England by Nunnelly

I then took the agent up without the knowledge of the experiments of Dr Nunnelly, of England, and had it made in Philadelphia by Professor Remington, and with two friends began experimenting in September, 1877, using it first on myself, and then upon my patients After satisfying myself as to its efficiency and safety as an anæsthetic, I laid the subject before the Pennsylvania State Medical Society in 1878, and a record of ten cases, with my conclusions, which were published in the volume of their Transactions for that year In August, 1879, I brought it before the British Medical Association at Cork, and in September of the same year, I presented a report of one hundred cases before the International Medical Congress at Amsterdam (to which I was a delegate from the American Medical Association), up to March, 1879, when the second edition of my work on anæsthetics went to press I had published a report of twenty five successful cases in quite a variety of surgical operations, and had not only employed it at my daily ear clinic, but also in the Jefferson Medical College Hospital, and administered it in April, 1879, to a patient of Dr Samuel W Gross, at the public clinic, when he (Dr Gross) removed a hyoid cyst in front of the neck of a child Dr R J Levis, who was at this clinic, for the first time saw it employed, and became much interested in its use

I thus compelled chemists to make it, by producing a demand for it, and gave them, through Dr Green, a good formula free from phosphorous, I interested surgeons all over the country to try it, and especially the surgeons of this city, by bringing it in every way before their attention Subsequently the whole number of cases in which it has been employed by myself and friends up to June, 1880, will number some eight or nine hundred

I can but feel disappointed that two deaths, not produced by it, should have been associated with it,[1] as such accidents will be employed by those having a prejudice against the ether, to condemm it on theoretical grounds[2] It is my firm conviction that although in several instances recently the use of this anæsthetic has been attended with persistent vomiting, in the hundreds of cases in which it has been employed, chiefly in Philadelphia, in not one single instance has it caused cerebral trouble, or any of the symptoms produced by the action of free bromine, which are as follows When dogs are confined in an atmosphere of bromine vapor, they suffer a profuse secretion from the eyes, nostrils, and fauces, with cough, hoarseness, dyspnœa I have experimented upon frogs, cats, dogs, rabbits and various other animals by subjecting them to an atmosphere highly charged with the vapor of hydrobromic ether, and in no instance was there the slightest effects as described above

PHILADELPHIA, June 2, 1880

"Deputy Coroner Beam made an investigation of the circumstances, as reported in *The Times* nearly a week ago, of the death of William Linderman, 18 years old of Schuylkill county, while upon the operating table at the Jefferson College Hospital on

[1] The bromide of ethyl as an anæsthetic by Marion Sims M D, LL D New York Medical Record April 3 1880

[2] In the discussion following the report of the fatal case by Dr Sims to the New York Medical Society Dr Squibb undertook to account for the poisonous effects of bromide of ethyl by assuming it to be a loosely molecular article easily decomposed that thus its administration is prone to be followed by an impregnation of the system with bromine and that if it remained as bromide of ethyl in the system it might not be harmful This theory has been shown to be based on insufficient grounds In the first place Prof Jungk has shown bromide is not a loosely molecular article," that in fact it is a very stable salt (for a salt it really is) and very difficult of decomposition much more difficult than chloroform In the second place the assumption that anæsthesia is due to a breaking up of the anæsthetic into its elements is nothing more than a hypothesis and one too which has little or nothing to support it The fact that it is one of the characteristics of bromide of ethyl that it is perfectly unirritating to the bronchi, goes to show that it is not decomposed if it were, the bromine in its composition one of the most irritant of substances would certainly manifest itself in its effects on the air passages

Wednesday last, under the influence of the new anæsthetic, bromide of ethyl, and about to be treated for stone in in the bladder. He had been about sixteen weeks under the care of Dr. R. J. Levis, one of the strongest advocates of the new anæsthetic, and was taken to the hospital by his direction. Linderman's health was very poor at the time. Dr. Ames, who applied the bromide, said no incision had yet been made, but Dr. John B. Roberts said it had. The patient was in such a condition that something had to be done, because he could not tide over the hot weather, 96° 98° in the shade.

"Dr. J. G. Lee, the Coroner's physician, testified that he found the brain congested, *the lungs far advanced in consumption, and the kidneys and liver enlarged* and two large encysted stones in the bladder. His opinion was that they could not have been safely taken out. *Linderman could not have lived over a week or two at any rate.* Dr. Lee said further, that he had experimented with the bromide on animals without bad results. In his opinion death resulted from exhaustion and prostration, the result of phthisis. The jury took the same view in their verdict."

In subjecting the new anæsthetic to this most severe test, we do not think our friend Dr. Levis was doing justice to it, knowing the extreme debility of the patient, and that the most simple nervous shock would render him liable to death. Hundreds of patients have thus died. Again, when ordinary ether, chloroform, or other anæsthetics cause fainting, which was no doubt the result in this case, respiration has to be resorted to, now we are reliably informed that when this useful means was resorted to by alternating and relaxing the chest walls, *the pus which was in this man's lungs was forced into his bronchial tubes and suffocated him.* Again we are very sorry that the valuable agent, nitrite of amyl, which has been found useful in such cases, was not employed.

In some recent experiments on animals, I crowded four ounces (the quantity stated to have been used by Dr. Sims) upon a dog for several minutes, by means of a tin inhaler, until he became apparently dead, with no perceptible action of the heart or lungs, but the expression of his eye was clear, and the pupil was dilated, while there was no secretion from the eyes or nostrils. The apparatus was removed in the space of four minutes, and he was exposed to the air when at once he began to breath, and by the end of the six minutes, he had almost entirely recovered consciousness. The dog did not seem much inclined to move for ten or twelve minutes afterwards. While this dog was only partly under the influence of this anæsthetic, having at first caught the inhaling apparatus with his under teeth, there was a good deal of rigidity, and slight tetanic movements of the extremities, but this was overcome by the free use of the ether.

Now, had we been using chloroform, just before we would have been ready to perform any experiments upon the animal, he would have been dead, and no removal of the anæsthetic nor the introduction of atmospheric air, would have been of any avail. Again if Squibb's rectified and absolute ether had been employed, we must have super saturated the animal, and been annoyed by the expectoration of large quantities of mucus. Then we frequently have seen tetanic convulsions, requiring several assistants to hold the patient, with great reduction of temperature, from the use of ordinary ether. The rapidity of the anæsthetic action of hydrobromic ether and its rapid elimination from the system by the lungs, are two of its chief merits for all operations that are not prolonged. If an operation is to be very tedious, and requires from one to two hours, we would advise the additional use of purified sulphuric ether to the anæsthetic. *We would therefore recommend pure hydrobromic ether in operations not lasting over forty minutes.* There is one great advantage in the use of this agent, that the administrator must attend to the anæsthetic all the time, he cannot watch the operation and forget the patient for a few seconds, his whole attention must be given to keep up its action. We have often felt sure that the wet napkin, from the water, in the ordinary ether pressed over the patients mouth by the weight of the body of the persons giving the ether, and watching the operation, were the indirect causes of the death of the patient. As an anæsthetic in labor, it has peculiar advantages in that it is so rapid in its effects, and the patient is comforted between the pains, but never passes into such a state of profound anæsthesia, that she is not aroused by the expulsive effort, and has all her consciousness about her, and there are none of the depressing effects of ether or chloroform. It is also most valuable in these cases in changing the position of the child, also in bringing forward the neck of the uterus into its proper position. In none of my cases was there disturbance of the bowels, pain in the back or head. To the country practitioner, who has to extract teeth or perform all the minor operations in surgery, it is a great boon, as it acts like nitrous oxide gas, it is well where a number of teeth are to be extracted, that a prop of hard wood attached to a string should be used so as to prevent such an accident as once occurred in Philadelphia under the use of nitrous oxide gas—the swallowing of a prop of cork. In many cases in which we do not want a very profound narcotism with hydrobromic ether, the muscles of the patient become rigidly contracted. This condition occurred in a recent case, when we administered ℥i of this anæsthetic and the operators finger was caught and pinched, as also his forceps, and yet before operating we could touch the cornea with impunity. Although the impression passed away very rapidly, we extracted twelve teeth with entire success, the patient promptly recovering consciousness, and not feeling the pain. In the following case the patient went under it very kindly. This patient was a man of very nervous temperament. With three drachms of the hydrobromic ether anæsthesia was produced without any struggling, and in four minutes from the time he had commenced to inhale it, the dentist had extracted ten teeth, and he had fully recovered consciousness, although he had just eaten a heavy breakfast of solid food. There was no nausea in either of these cases.

In a recent case of cataract extraction, the patient went beautifully under the influence of the anæsthetic, extraction was accomplished, and the patient recovered so as to be able to count fingers, yet owing to some strong coffee which she drank, from dyspeptic symptoms, or the swallowing of water soon after the operation, she became very sick at her stomach, and vomited for almost twenty four hours, and yet the case did well In case of operation for torticollis in a woman, she swallowed so much air with the ether, that as a consequence she complained of pain, of a hysterical character, in lower part of the abdomen, the same which is often the result of nitrous oxide gas inhaled, and too much air admitted

We received a letter from the late Dr J Patterson Cassells, of Glasgow, a distinguished aurist and a surgeon to the celebrated Glasgow Infirmary He writes that he has used a specimen of the hydrobromic ether, which I gave him at Cork, as vapor, in diseases of the middle ear, and has also employed it as an anæsthetic with success

As I have before stated,[1] "*no anæsthetic can be used with absolute safety*" See "A Presumable Ether-Death from Heart Failure," by John B Roberts, M D, *Medical News*, Sept 27, 1884, by the same author, "Ether-Death," *Medical Times*, June 4, 1881 "Case of Death following the Inhalation of Chloroform," reported by P L Helsman, M D, Albany (Ga) *Medical News*, Sept 27, 1884 No anæsthetic has been yet found that is free from danger, all will kill Chloroform kills in round numbers about one in every three thousand Pure ether is, next to nitrous oxide, the safest anæsthetic, only seventeen cases of death, and many of these doubtful, but it requires boldness and freedom in its administration If slowly or ineffectually administered it is apt to produce a free secretion of bronchial mucus, which occasions troublesome coughing If nitrous oxide is administered alone as a prelude to ether, the secretion of mucus is less troublesome, but there is a great amount of venous congestion and the tissues become gorged with blood, so that every incision tends to bleed Some surgeons use the mixture which is known as A C E, which contains one part by measure of absolute alcohol, two of chloroform, and three of Squibb's ether This is not simply a mixture, the absolute alcohol,[2] 99 4 per cent, causes a solution of the other two and they evaporate together But the mixture should be administered freely from a cone of felt or flannel, with a paper covering, and the desired effect should be produced as rapidly as possible The best results are by the agents which produce rapid effects, and which are as rapidly recovered from No other has produced such rapid anæsthesia as the hydrobromic, and it is the most rapidly recovered from

There are certain conditions of the system that forbid the use of anæsthetics Again, there are certain of this class of agents that should not be employed in prolonged operations, as, for instance, the "bichloride of methylene," bichloride of ethedene, and bromide of ethyl One or two deaths have followed the improper use of each of these agents, even when recommended by a committee appointed by the British Medical Association and by Sir Spencer Wells[1] As the result of the observations and experiments with the bromide of ethyl, my conclusions have been that one hour is the longest time that a patient should remain under the influence of this anæsthetic with safety," just as is the case in the administration of potent remedies like morphine, atropine, hydrocyanic acid, etc , no one will attempt to ignore or not use such valuable remedies because in certain individuals and under certain conditions of the system they produce death Can we in all cases rely on the experiments on animals as a true and absolute guide to determine our course in the human being? We think not, for it is a well-known fact that many animals eat plants which are deadly poisons to man, and certain anæsthetics are fatal to dogs Again, certain salts taken with impunity by man are poisonous to animals Experiments in the laboratory with the prolonged use of anæsthetics of two hours[3] duration, cannot be taken as the results against those obtained by numerous careful observers on themselves and others Clinical experience has now reached at least two thousand[4] well authenticated cases in which the bromide of ethyl has been employed with safety since 1880, when the two deaths were reported

I will quote only a few of the many impressions and experiments with the pure bromide of ethyl[5] The first is a gentleman very familiar with all the other anæsthetics, and his experience should be worthy of confidence

The following trials of this new anæsthetic were made to test its merits and to obtain personal experience of its effects For the record of occurrences after loss of consciousness, and for care and attention during administration, he was indebted to his friends, Drs Pilate and Conklin

First Experiment—March 14th Four hours after eating a moderate breakfast he proceeded to inhale the bromide of ethyl, in the recumbent position, and from a bottle just opened labelled "1 oz bromide ethyl" About one-fourth of the contents was poured into an Allis ether inhaler The first and immediate sensations upon inhaling it were a sharp pungent impression on the air-passages, a sense of warmth rapidly extending, and exhileration With the second inspiration he felt a decided influence upon the brain, and began to talk, anxious to continue speaking as long as possible, and to state his sensations A rapid beating in the ears is a constant symptom with him in taking chloroform, and immediately precedes entire loss of consciousness He marked its presence now, and also its early appearance It could not have been later than the third, or possibly the fourth, inspiration when he noted it, and this, as with chloroform, was the last sensation

[5] Two New Anæsthetics' by J C Reeve M D Dayton Ohio Cincinnati Lancet and Clinic

Upon opening his eyes after recovery from the anæsthetic, he immediately collected himself and could remember all, could talk clearly and had no confusion of thought. He felt a slight sense of nausea and a feeling of languor. Eight minutes afterwards he got up and walked about without dizziness, and was confident he could have done so sooner. He did not attempt it sooner because he felt that sickness would ensue if he arose. The feeling of nausea remained until he commenced eating his next meal, about forty minutes later.

Second Experiment.—Pulse at beginning, 80, just after ascending stairs. Two drachms administered. Symptoms began to be manifested after two respirations. Spoke of general warmth, pleasant sensations and beating in the ears. Anæsthesia produced in one minute and a quarter, in another quarter minute it was profound, as tested by a knife point. Pulse during the first minute ran up to nearly 100, then fell during next minute to about 70, feeble and intermittent. Pupils unchanged, normal, no struggling or excitement, but tetanic clutching of the inhaler so that it could not be gotten away only with difficulty. The anæsthesia lasted one minute and a half, then awakening without mental confusion. Pulse seven to eight minutes later, 64. He was not satisfied with this experiment, particularly in regard to the irregularity and intermittence of the pulse, not a very assuring symptom in anæsthesia, and a result not agreeing with other observers. He had a suspicion from this fact, and from the nausea, that the specimen was not pure. The bottle bore the name of a house which is always a guarantee of the good quality of medicines, but in the early period of manufacture of a new article, it would not be surprising if perfection was not immediately attained, he therefore obtained another specimen,[1] and one week after the above trial again inhaled it.

Third Experiment.—Being in the recumbent position, four hours after eating, one drachm, by measure, was poured into Allis's inhaler. He tried to take it slower this time, and count the respirations aloud to mark when conscious action ceased. He immediately felt the same grateful and pervading glow of warmth all over the body, counted to the seventh respiration, beating in the ears was again the last recognized impression. Pulse before, 80, at the end of the first minute, 120, one and a half minutes, at the rate of 100, at the end of two minutes, 78, no irregularity or intermittence. Pupils unaffected. Totally unconscious in one minute. Consciousness returned in three minutes.

It was his design to push the inhalation farther this time, and to test the muscular relaxation as well as to decide in regard to the irregularity of the pulse. Feeling that this had not been done, after about fifteen minutes he took it again.

Fourth Experiment.—Two measured drachms were poured on the inhaler, and he placed it over his mouth and nose. The impression was much stronger on the nose and air-passages, and the first inspiration made him cough. He then counted to the third inspiration, and was gone. Pupils the same as before, unaffected, pulse before taking, 78, at the end of the first minute, 124, one and a half minutes, 100, and of two minutes, 78, no irregularity or intermittence. Anæsthesia in one minute. At the end of three minutes from the time of beginning he got up and walked across the room, and could have remained up. As an effort at prolonged anæsthesia this was not, therefore, a success. In eighteen minutes he was on his way driving to see a patient. He had not the slightest nausea after these two inhalations, felt, if anything, better than before.

Fifth Experiment.—His next trial of the agent and first attempt at administration, was not satisfactory. The patient was a man aged about 50, a wiry, muscular fellow, of the type and build likely to give troublesome symptoms with any anæsthetic. He was placed on the table for an operation for hæmorrhoids, by Dr. Conklin. He had brought with him for the administration a large conical sponge, with which he constantly gave the A. C. E. mixture. Upon this he poured two drachms of hydrobromic ether and placed it over his mouth and nose. After one long deep inspiration his face became deeply flushed, and he soon began to talk and then to shout. More of the liquid was poured on the sponge, but his movements interfered with the inhalation of it with promptness, muscular rigidity then came on, and was marked, respiration was very nearly if not quite stopped for a time by tetanic spasm of the chest. These symptoms were almost as bad as he had ever seen from ether, chloroform, or the mixed vapors. He had seen worse muscular action and rigidity, but this was as bad as generally met with. During this time the ether was rapidly added until the supply was exhausted (13 drachms), and sufficient relaxation was not produced to make the operation feasible. No observations could be made, of course, of the patient's pulse. He recovered consciousness quite rapidly, as compared with other anæsthetics, and suffered no unpleasant after-effects.

This was not, of course, a fair trial of the remedy. The mode of administration was decidedly faulty. It is an ether, and must be given as an ether, and that this is imperative is the lesson to be learned by this failure.

"The personal experience with hydrobromic ether fully sustains the observations of others as to its exceeding promptness of action, and the rapidity with which recovery from its effects takes place. It is also more pleasant to inhale than chloroform, which is not very unpleasant, and infinitely pleasanter than ether."

In my own experiments on animals I found that frogs, placed in a watery solution of ethylic bromide, become as completely anæsthetized as if they were immersed in an aqueous solution of chloroform.[1] Berger states to the Société de Chirurgie (*Le Progrès Medical*) that he had been impressed by the rapidity with which these animals succumbed to its vapor. Terrillon administered the vapor of ethylic bromide to eighteen dogs without accident to any one of them. In the writer's more recent experiments with the vapor of ethylic bromide he crowded four ounces

---

[1] Opt. cit. "Artificial Anæsthesia." Turnbull.

(the quantity stated to have been used by the late Dr Marion Sims, of a very impure article,[1]) upon a dog by means of a tin inhaler, in which was a sponge, strapped to his head, until he became apparently dead, with no perceptible action of the heart, or respiration, but the pupil was clear and dilated, while there was no secretion from the eyes or nostrils The apparatus was removed, and in four minutes he began to breathe, and at the end of six minutes he had recovered consciousness, but was not inclined to move for ten or twelve minutes In the beginning of the inhalation there was a good deal of rigidity and slight agitation In twelve cases there was muscular relaxation, and in six a period of agitation, no death In order to produce anæsthesia, it was advisable to administer the ether vapor very freely and without admixture of but very little atmospheric air, on account of its volatility

In Terrillon's experiments muscular relaxation occurred in human beings in two or three minutes, at times there was congestion of face, neck and upper part of the chest The pupils did not contract, but were dilated The pulse was always quickened, and every fresh dose caused fresh acceleration Respiration was always hastened, and a hyper secretion of the buccal and pharyngeal glands took place Sensibility and consciousness returned with great rapidity, vomiting was not uncommon both during insensibility and sometimes for hours after Verneuil, at the same meeting of the Sociéte de Chirurgie, stated that one patient, a woman, to whom he had given the vapor of ethylic bromide, was asleep in an instant, and Terrillon stated that anæsthesia may be produced in less than a minute In our own experiments the shortest time necessary for primary anæsthesia was thirty seconds

Dr W C Wood found, by experiments upon animals, that if the vapor of ethylic bromide be given with moderation, anæsthesia may be produced without notable reduction of blood-pressure In the experiments of Dr C C Gay, of Buffalo, the agent employed was evidently, from color and taste, impure, as was also that used by Dr D C Wilkinson,[3] of Galveston, Texas In Dr I C Moore's cases the ethyl was abandoned for ordinary ether, even when the insensibility had not passed off, owing to the exhibition of so called bad symptoms, great excitement, with intense and persistent retching and vomiting, with venous engorgements The article was stated to be pure, and was from Wyeth & Bro

The great demand for the article and the cost and care requisite, caused many imitations to be placed upon the market, and even the original manufacturers did not take sufficient time to purify it, so that for a time the article contained carbon bromide (CB_4), and free bromide and bromoform These were found in the specimens employed by Dr Sims, in the form of a brown acrid liquid, with a pungent and disagreeable odor Twenty drops of this given to a rabbit which had previously taken two grammes (thirty grains) of pure ethylic bromide without the slightest ill effect, produced irritation of the gastro-intestinal tract, followed by death in eighteen hours[1] As observed by Dr Henry M Lyman "All experience shows that the administration of anæsthetics to such patients is attended with danger Even sulphuric ether may prove fatal if the kidneys are seriously damaged, and pulmonary disorganization is a well-known source of danger during the inhalation of anæsthetic vapor The administration of chloroform to such a patient would have been a very hazardous undertaking The fatal results in these cases cannot be so charged against the particular anæsthetic employed, as against the exhibition of any anæsthetic agent whatever "

That ethylic bromide may be employed with ease and success, has been abundantly proved by the experience of many observers M Bourneville has administered it to a large number of patients in the Salpêtrière Hospital, for the arrest of paroxysmal hysteria and of epilepsy He has also administered it daily by inhalation for fifteen or twenty minutes, with the fortunate result of considerably diminishing the frequency of the convulsive paroxysms In several of these cases the temperature was depressed about half a degree centigrade during the act of inhalation Immediately after the withdrawal of the anæsthetic the normal degree was recovered, and sometimes even surpassed The pulse in about five hundred administrations was somewhat accelerated during the period of inhalation In six instances only was retardation observed Respiration in like manner was almost always accelerated A copious overflow of tears was nearly always remarked The urine never contained either albumen or sugar, and the quantity of the liquid was not affected Rigidity of the limbs and tremor involving the upper extremities, were sometimes noted Daily inhalations for a period of two months exercised no unfavorable influence over the general process of nutrition, five patients found their weight increased during this period

There are certain preparatory precautions which are necessary to the safe inhalation of the bromide of ethyl

1 All tight-fitting garments in and about the neck and chest should be loosened

2 The saturated ethyl vapor must be inhaled almost to the exclusion of atmospheric air The best form of inhaler is a thick towel folded in the form of a cone, closed at the apex with a large pin, between the folds of the towel place a sheet of newspaper

3 Instruct the patient in advance to make deep and long inspirations In the cone place about one drachm, by measure, and at once cover the nose and mouth with it, and do not remove the cone until anæsthesia is produced, which will be in from twenty to thirty seconds

The anæsthetic sleep will not last more than from two to three minutes The patient retains the usual healthy color of lips and skin, and the pulse first becomes rapid, then slower and stronger as the narcosis becomes profound. The patient, as a rule, awakens suddenly and completely, but if there is nausea or much agitation, it is best for him to remain quiet and in a horizontal posture for some time.

---

[1] The writer received this specimen of the article from his own hands and after testing it found it very impure and of a brown color

[3] Medical Record May 15 1880

[1] D S Wolff Am Journal of Pharmacy May 1880 The writer also obtained a portion of the same liquid from Dr Wolff and on comparing it with the specimen from Dr Sims found it to be the same

[2] Artificial Anæsthesia and Anæsthetics Pp 220 221

Perhaps no operations are more painful than those on the eye, eyelids, or eyeball, in a sensitive person, and there is no anæsthetic that I have found so applicable as bromide of ethyl in such operations. I recently administered it for the removal of a deep seated tumor of the eyelid, the operation being performed by Dr. Hermann Knapp, of New York. The patient took the towel in her hands and applied it to her face with about two drachms of the ether, and in thirty seconds she was so completely anæsthetized that she was not conscious of one particle of pain until the tumor was entirely removed; she had no nausea whatever, or any other disagreeable symptom.

Again, in operations on the diseased mastoid cells, I have employed it in some twenty cases with entire success, and in a very recent case in which the whole bone was diseased and much of it had been removed, an opening had to be made of a most painful nature. I administered the bromide of ethyl to this patient, who was very much exhausted by profuse discharge from a large cancerous growth. The patient went under the influence of this anæsthetic with the most delightful effect, not suffering at all from the operation, and going to sleep after it without a bad symptom.

We have, in times past, heard a great deal of the injurious effects of bromides, and at first we felt that it might be so, reasoning in a chemical way, and for a time we gave the hydrobromic acid and ether with great caution, never exceeding thirty drops three times a day. But not so now; experience has taught us that we can use it, if well diluted, up to sixty drops three times a day without any injurious results. To obtain its full physiological effects in epilepsy, certain cases of pulsating tinnitus aurium, and in preventing the disagreeable cephalic symptoms occasioned by quinine and iron in these various nervous affections, we have found it at times very satisfactory. The salts of this agent, bromine, can be and are used with the greatest freedom in the form of bromide of potassium, sodium, and lithium, in doses of grs. xl–ʒvi, given in six days without the least fear of its injurious effects upon the most delicate stomach, and relieving, as by a charm, convulsions, epilepsy, whooping cough, sleeplessness, headache, cerebral disturbance, tetanus, and all forms of mental derangement.

As well observed by Dr. Chisolm:[1] "For office use I find the bromide of ethyl invaluable on account of its promptness, efficiency, evanescent nature of the anæsthesia, indeed, the absence of nausea, and the perfect comfort with which patients operated upon can leave my office within a few minutes after the ethylization."

Bromide of ethyl should never have taken the place of chloroform or sulphuric ether where any tedious operations are to be performed, but there is no reason why this useful anæsthetic should not be employed in all operations in minor surgery and in those on the eye, ear, throat and nose, having everything ready in advance so that the patient shall be as short a time as possible exposed to the evil effect of an anæsthetic.

I conclude this brief paper by the results which I obtained, and the conclusions I then arrived at (1879), and I still consider them my firm opinion at the present time, after using the article from 1878 to 1884 in all my office operations.

	Minutes	Seconds
Shortest time taken to place a patient under the primary anæsthetic influence	0	30
Longest time	5	00
Average time	1	30

I did not then advise that bromide of ethyl should be resorted to in protracted operations, and I never have employed it in any case longer than forty minutes, and have never used more than four ounces of the pure ether in one case.

1502 Walnut St., Philadelphia, Oct. 12, 1885.

NERVOUS PAROXYSM.[1]

BY HENRY T. BYFORD, M.D.,

OF CHICAGO.

On account of the frequency with which syncope, shock, collapse, hysteria and other pathological conditions have been confounded in the diagnosis of the intelligent practitioner, I have considered it worth while to record a few cases of a hitherto obscure form of nervous paroxysm, with the object in view of separating it from the several diseases with which it is confounded, and of investing it with a distinct entity.

I copy the following case from the *Obstetrical Journal of Great Britain and Ireland*, for October, 1874:

"On Sunday morning, April 5th, I was called at 9.20 to see Mrs. C., aged 41, in labor of her tenth child. I reached the house at 9.50, and found child and placenta attached expelled. The nurse did not arrive for half an hour after I reached the house, but an intelligent servant informed me the child had been born fifteen minutes prior. I found the uterus perfectly contracted, no trace of hæmorrhage beyond what is usually lost, and her general condition perfectly quiet.

"After bandaging her securely, a well adjusted pad being placed over the uterus, I admitted her husband, who congratulated her on her safe delivery. He remained for about twenty minutes, and then left the room. Five minutes had scarcely elapsed when I noticed some pallor coming over the face. Thinking hæmorrhage might have been the cause, I examined carefully and found none externally; then I opened the binder and removed the pad, with the same result. The uterus was well contracted. At this time the faint was well marked. I then gave tablespoonful doses of brandy with volatile ammonia, and applied sinapisms over the heart and calves of legs. At the end of thirty minutes she began to revive, which was marked by *vomiting of hard boiled*

---

[1] Read before the Chicago Medical Society, Oct. 2d, 1885.

egg and seed cake. During this faint I thought she died. The rally continued about thirty minutes. She then wanted to be raised in bed, and *complained of want of breath.* A pallor came over her countenance. I again examined for external and internal hæmorrhage, and found none. During this examination *she grasped my neck and raised herself upright.* I immediately placed her in a recumbent position, plied her with brandy again, and ammonia and beef tea. I called a consultation, but notwithstanding our united efforts, she never rallied from this. Half a bottle of brandy and half an ounce of volatile ammonia were used. I may mention she was an anæmic woman. *She suffered from mucous diarrhœa for a period of two months* (the sixth and seventh), which injured her health very much. Beyond a weak heart, I could find no other evidence of disease. Can you, or any of your readers, give any insight into this case?"

At one of the clinics in the Mercy Hospital, Chicago, during the winter of 1871 and 1872, I witnessed an operation for varicocele upon a young baggageman of an exceptionally powerful physique. One morning, a few days later, word was sent to the house-surgeon that the patient was dying. Armed with brandy and ammonia, the excited young graduate hurried to his bedside and, finding him in an apparently dying state, gasping for breath, commenced pouring brandy and ammonia down his throat. But the brandy, ammonia, electricity, raising of the foot of the bed, etc., all failed to prevent a fatal result. The heart was subsequently examined without realizing the cause of death. Two or three days later the body appeared in the dissecting room, as magnificent in form as on the day of the operation, but turned blue from the shoulders up, and marked with unmistakable signs of death from asphyxia. The sudden change from a life of great physical activity to absolute inactivity, in a horizontal position, along with the indulgence of a good appetite, had led to an attack of reflex cardiac disturbance, dyspnœa, and mental confusion. Unable to swallow properly, the brandy and ammonia had found their way into the trachea, and strangled him.

Four years ago I was hastily summoned to see a patient, convalescent from pelvic cellulitis, who was reported to be dying. I found her pale, haggard, bluish and sunken about the eyes, and gasping for breath. She was just getting over a paroxysm, and begged me not to let her die. I quieted her fears, and thus made her easy for the time, but gave her no medicine (although she had a mild attack of dyspnœa soon afterwards), except cold water to drink and mustard to the epigastrium. During the two paroxysms which she had before I came, *her breath seemed to leave her, and once she threw herself out of bed in her distress.* Great exhaustion of course followed each attack. She could not tell whether she had entirely lost consciousness or not, but described her physical and mental suffering as infinitely greater than during her ordinary fainting spells. Her attendants all thought her dying.

Although previously unable to take any but the lightest nourishment, she had that day, against her inclination, *been fed a large bowl of thick pea-soup and a poached egg on toast.* As the attacks were soon over, I gave no emetic. The pulse remained at 120 and the temperature near 100° F. for two days, when they became normal, almost at once, *after the vomiting of a large quantity of dark grumous material.* She then had no more trouble. Had ammonia been poured down her throat during one of the paroxysms, her death might have been as great a mystery as was that of the two other cases related. The dyspnœa and distress, already existing, would mask the fatal action of the irritant upon the glottis and trachea.

The three cases explain each other. The parts of the first case which I have italicized show it to have been no ordinary faint. Its similarity to the third case mentioned (see italics), in which the patient, almost an habitual fainter, recognized a great difference, make it appear like a similar, but perhaps severer, paroxysm. The second case could hardly have been a case of failure of the heart's action, but is chiefly interesting in showing how the treatment may be infinitely more dangerous than the disease.

The following is a mild case from notes taken at the time of attendance.

Mrs. T., aged 33 years, with three children, was treated by me a couple of years ago for sterility of four or five years' duration. The uterine disease present did not seem to cause any inconvenience. She bore a child twelve months ago, and had felt well up to the time of this sickness. Is plump and well-nourished. While listening to a funeral sermon in church she was attacked with a feeling of smothering about the heart and chest, and a feeling of weakness and trembling in the limbs. She experienced a peculiar sensation of swelling about head, with great mental confusion and alarm, and had a great fear of falling dead as she had heard of others doing. She hurried out of church, and was soon relieved by cool air and cold water douches. Two days later she had another attack during regular services at church. Was taken with similar feelings the next day in the street car, on her way to my office. Had a feeling of heaviness, and spells of gasping, previous to attacks. She came to ascertain whether she had heart disease or was threatened with apoplexy. She exhibited a putty tongue and sallow skin, as well as other evidences of disordered digestion. A few days later she had still another paroxysm. A physician in the neighborhood, who was called in at the time, stated that her countenance evinced extreme anxiety, that her extremities were cool, her pulse somewhat depressed, and her mental condition one of nervous exaltation and confusion, as was subsequently proved by her contradictory statements. A few days after this she again had a slighter attack, in which cold extremities, head symptoms and anxiety were the most noticeable symptoms of which she complained. The treatment consisted, in the main, of dilute hydrochloric acid, laxatives, and antispasmodics (such as chloral by night and valerian by day), a simplified regimen, massage, and, later, quinia and other tonic measures.

It may not be amiss to relate here the case of Mrs. O., who was under treatment by the same physician

Arriving at her house a little ahead of him, I noticed an acid mixture and a bottle of elixir of valerianate of ammonia, dated a day or two later than the occasion upon which I recommended him to give the same to Mrs T The patient complained of having had attacks of a sensation of fluttering and pain in the region of the heart, with great difficulty, and at times total disability of speech, oppression across the chest, queer feelings about the head, ringing in the ears, flashes of heat, headache and pain under the shoulder blades In the less pronounced paroxysms, one or more of these symptoms would be absent, but in all, anxiety of countenance, and fear of immediate death, were prominent The notion that she was to die in one of them kept up a mild condition of shock, and could not be got out of her mind The pulse was fair, and the temperature normal The tongue was decidedly coated She had a great deal to say about a feeling of general weakness After a careful examination, I could discover no exciting cause except prolonged emptiness of a disordered stomach

She had had a miscarriage about seven months before, and had since received local treatment for an ulcerated cervix Her sister was in an insane asylum The attending physician informed me that she had been taken a month before with chills and vomiting, followed by evidences of malaria and hepatic derangement, and, although she at first improved upon quinine, iron and cholagogues, she had lately been getting weaker was then bedridden, and subject to these paroxysms both day and night He thought that her nervous temperament, the mischievous gossip and anxiety of her neighbors, and prolonged nervous debility, had conspired to render her partially insane

We put her upon 15 minims of acidulated tincture of iron three times a day, a liberal but carefully systematized diet, and ammoniated valerian as might be found necessary Strychnia was to be given as soon as the stomach would take kindly to it, and arrangements were made for getting her out of bed We relieved her mind and gained her cooperation by promising a speedy and perfect recovery Although her ailment was almost chronic, she did not have another paroxysm, and was able, four days afterwards, to travel two miles in the street cars to the doctor's office The case was, upon the disappearance of the paroxysms, transformed into one of simple nervous debility

The most common exciting causes, according to my experience, lie in the digestive system, although subsequent observation may give the cutaneous, osseous, sexual, and urinary systems some prominence Debility, plethora, impure states of the blood, sudden changes of habits, severe strains upon vital forces, parturition, functional or organic diseases, etc , are predisposing causes

The attacks are of a convulsive character, but differ from ordinary eclampsia in that consciousness is not usually lost, nor the voluntary muscular system always affected Internal convulsions, or the laryngismus stridulus of children, is a disease of the same nature Nightmare, and the sense of suffocation sometimes felt after the taking of heavy or irritating food upon a disordered stomach, may be considered as mild or modified forms Shock may be, or become, a complication of severe cases, and cause them to be diagnosed and treated as syncope It will be interesting and perhaps instructive to compare the prominent symptoms of the two

TRUE SYNCOPE	NERVOUS PAROXYSM
1 Often preceded by a feeling of oppression about the epigastrium, or nausea and general malaise Patients feel the attack coming on	1 Often preceded by nervous irritation, heaviness about the stomach, and frequent desire to take a deep inspiration (gaping), sometimes by a feeling of nervous exaltation, or equanimity greater than usual Onset is usually sudden
2 Pallor, vacant expression of countenance, and mental calm in the beginning, with dullness of special and general sensation	2 Pallor, anxious countenance, mental distress in the beginning, with acuteness of special and general sensation
3 Muscular relaxation	3 Muscular rigidity or activity
4 Dyspnœa, if any, not distressful—objective rather than subjective.	4. Dyspnœa distressful—more subjective than objective
5 Unconsciousness absolute	5 Seldom absolute unconsciousness *Mental confusion or* incapacity
6 When not fatal, attack passes away rapidly, especially if patient in recumbent position	6 Passes away gradually, more rapidly if head and shoulders be elevated
7 Temperature normal or below (unless elevated by disease)	7 Temperature normal or above
8 Seldom recurs if head be kept low	8 Usually recurs, or threatens to recur shortly, even if patient lie down
9 Heart's action greatly depressed	9 Heart's action irregular, spasmodic, and only moderately depressed
10 Seldom very disagreeable recollections of distress during the attack	10 Very disagreeable recollections of distress during the paroxysms
11 Stimulants afford relief	11 Stimulants aggravate

It will be observed that the attack is not at all related to syncope, with which it has been confounded, but is in reality a paroxysm or involuntary frenzy (usually of reflex origin), in which the interference with vital functions is due to spasmodic action, rather than relaxation, of the respiratory and circulatory muscles In searching the books for a description, we will find that reflex syncope is made to include some cases So called hysteria receives many into its myriad arms, while nervous prostration and gastric irritation have been stretched to cover a large number

The treatment may be conveniently divided into three parts

1 Management of the paroxysm
2 Removal of the cause
3 Restoration of the disordered animal economy to its normal relations

The management of the paroxysm requires more calmness and patience, on the part of the physician, than active interference And especially should stimulants, such as brandy and ammonia, be reserved The indications are rather to diminish the anxiety, or shock, by assurances of a speedy recovery, and to allay the reflex nervous irritability by such remedial agents as massage, counter irritants to the epigastrium, nape of neck, or spine, cool air, cool drinks or douches, and heat to the extremities Valerian, cannabis indica, bromides, chloral and the hot bath may be resorted to when milder measures fail

3100 Forest Ave

A CASE OF RETAINED DEAD FŒTUS[1]

BY J A DIBRELL, JR, M D,

OF LITTLE ROCK ARK

A brief report of a case of this kind, seen some years ago, in consultation with Dr William Thomson, of this city, and Dr D H Dungan, is deemed of sufficient interest to engage for a short time the attention of this Society The case is believed to be an unusual one in several particulars

Mrs A , aged 32 years, of a rather delicate constitution, mother of two children, the youngest 10 years of age, had up to May, 1877, been regular in her catamenial periods, and had otherwise enjoyed her usual health In quantity, her menses had always been very free, generally lasting five or six days In this month her menstrual molimen made its appearance at the usual time, but had never in years before been deficient in quantity, and though always painful, was more so now than formerly She had uneasy sensations, and greater discomfort than was her habit Following this "period" in regular order, appeared the ordinary symptoms and signs of pregnancy, viz nausea, vomiting, changes in the color and size of the mammæ, and gradual enlargement of the abdomen In June, July, August and September, her menses appeared at the proper time She with good reason believed herself to be pregnant, though constantly oppressed with the fear that something was wrong During three months she suffered continually with nausea, and her general health began to decline

On the 20th of September, as nearly as she can recollect, she menstruated for the last time This period was one of great suffering The menses appearing regularly, though abnormal in quantity and character, in the presence of what were considered unmistakable evidences of pregnancy, was a constant source of perplexity and anxiety to the patient She was confident at times that she was pregnant, and at others disposed to attribute her condition to disease About this time, she experienced what she believed to be movements of the child About October 1 she was more confident that she felt life These movements were always vague and ill defined, and she thought it quite possible that she might be mistaken altogether, but after this date she is very positive that she felt no movements whatever in the fœtus On November 22, a sudden discharge of blood and water from the uterus took place, accompanied and followed by agonizing pains in the back, and later by bearing down pains The patient kept her bed for five days, and labor not having terminated, but, on the contrary, the pains having become less poignant and less violent, she tried to get up, and leave nature to take its course From this time on, there was always a fetid discharge from the womb

During the month of December and half of January she had labor pains quite constantly, a period of repose then following

Dr Thompson, the attending physician, to whom I am indebted for the privilege of seeing this case, and also for most of the above history, had, during this long siege, repeatedly but ineffectually made efforts to stimulate the uterus to expel its contents, by means of oxytocics and sponge tents The os was never dilated to a greater degree than would just admit of the introduction of the end of the index finger

On February 11, 1878, I saw the case for the first time The os, on examination, was found to be dilated to the extent already indicated It was firm and unyielding It was indurated and felt not unlike cartilage The anterior lip of the cervix was enormously hypertrophied, suggesting at once the idea that the enlargement was due to a pathological growth rather than a simple hypertrophy An attempt to forcibly introduce the finger into the uterus had to be abandoned in consequence of the suffering the procedure induced A sound was tried, and passed two and one-half inches, but Dr Thompson had previously been able to pass it to a depth of four and one-half, between the uterine wall and the secundines, as subsequent events appeared to prove

The patient was now very feeble She had had fever for some time, and was much exhausted by pain and anxiety Since November she had a dark-colored and highly offensive discharge, and we believed her already septicæmic

February 14, the case was again seen with Drs. Thompson and Dungan The condition of the patient was much the same as it was at the time of my first visit, three days before, except that, on the 13th, the membranes were ruptured, and a discharge of water took place, in quantity fully as great as is commonly lost in ordinary labor The uterus was now diminished in size, the fundus was midway between the umbilicus and pubis, having descended from a point two fingers' breadth below the umbilicus Since this event, the pain had been almost continuous, but no further dilatation of the os took place It was suggested that another attempt should be made to dilate the os with sponge tents

The next day, February 15, Dr Thompson succeeded in introducing three tents, which in a few hours dilated the os to nearly the size of a silver dollar The feet of a fœtus could now be reached, and were finally brought down, the patient being under the influence of chloroform Much difficulty was experienced in extracting the trunk, and the head refused to pass through the os In making traction, as had been anticipated, the head separated from the trunk and remained in the womb As the os was not sufficiently dilated to admit of the introduction of obstetric forceps, Loomis's placenta forceps were applied to the head. As soon as the head was seized, the forceps would slip and the head roll around in the uterine cavity. Some hæmorrhage now occurring, it was feared that in the introduction of the forceps the placenta had been partly detached, and our patient being in no condition to lose blood, further attempts to deliver with this instrument were abandoned.

---

[1] Read before the State Medical Society of Arkansas April 23 1885

Introducing the hand into the vagina, prolonged faithful efforts were made with the fingers to dilate the os, but without success. Two fingers could be introduced into the womb and carried beyond the head, but the delivery could not in this way be effected. Attempts were made to break down the head, but in this also we failed. A process of boring and scratching was now resorted to, by which means a hole was made through the scalp and skull, or in an interval between the bones, and the head was brought out on the end of the index finger.

The placenta was adherent, very soft and friable. In attempting to detach it the fingers would pass through it, the mass offering but little resistance. In color it was of a pinkish hue, contained but little blood, and had evidently undergone fatty degeneration. Holding up a large piece between the fingers it would tear away from its own weight and fall to the floor.

The fœtus, we believed, had attained the age of at least four and one-half months, and had probably been dead about the same length of time, judging from the history of the case, and not from the appearance of the fœtus itself.

We had expected to find a highly decomposed fœtus, from the fact that the discharge from the vagina had for so long a time been of a putrid character. But in this we were mistaken. It had, indeed, undergone post-mortem changes, but there was but little odor. The tissues were soft, flaccid, and the skin, that portion which remained intact after rough manipulation, was of a deep red color. The brain was soft and almost liquefied. The trunk was nearly eviscerated during delivery.

This case, which made a good, but slow recovery, has connected with it several points of interest.

1st. The rather uncommon occurrence of the continuation of the menses for months after conception. A case of this kind pursuing a favorable course to the termination of gestation, is looked upon as a physiological anomaly, and but little importance attaches to it. But, occurring under the circumstances above related, it must of necessity weigh heavily in arriving at a diagnosis as to the existence or non-existence of pregnancy, a most important problem in all cases to be solved, and especially so in one where the character and reputation of the patient may be involved. In the present case, had we attached undue importance to this one symptom which was presumably present, to the exclusion of others, we should have been led astray. And any one confronted with cases of this kind must admit that there are various difficulties as to diagnosis, whether the contents of the uterus be a fœtus or a morbid growth. But notwithstanding these facts, it is often of immense importance to form a correct conclusion. But if, in the very nature of the case, a satisfactory diagnosis cannot be made, a very guarded opinion should be given. Medical literature contains the record of many cases where the loveliest characters and purest natures have labored for a time against the baleful and unjust suspicion of illegitimate pregnancy, based upon the opinion of physicians, which time alone proved was not pregnancy, but disease.

2d. The long continued, determined, but fruitless efforts of the womb to cast off its foreign contents.

It is worthy of comment that the muscular contractions of the womb began shortly after the mother ceased to observe what she believed to be the movements of her child, that is to say, about the time it perished.

3d. The hypertrophied and unyielding condition of the cervix.

The length of time a dead fœtus may be retained and tolerated by the uterus seems to be indefinite. Cases have been recorded in which the devitalized fœtus has been retained, in some instances, for years, without giving rise to any great inconvience or impairment of the general health.

Dr. Bauer says that the length of time of retention of a dead ovum has more than a passing interest, beyond its pathological considerations, namely a moral interest possessing vital bearings in a medico-legal point of view. The entire absence of decomposition which the fœtus manifests on expulsion, together with the fact that during its retention there has been at various intervals a discharge of blood from the uterus, supposed to be catamenial may give rise to the mistaken, and perhaps embarrassing conclusion that the expelled ovum is the product of a conception as recent in date as the size of the fœtus would indicate without the consideration of retention after its death. Instances are not unlikely to occur wherein a woman becomes a widow at the first, second, or third month of gestation, the ovum at the period being blighted and remaining in utero to the utmost limit of gestation, and on expulsion presenting every appearance of an abortion of the mere common type. The *date of conception* becomes the delicate point, and an innocent woman suffers, perhaps, unjust accusation touching the purity of her character.

Playfair says, on the subject of the changes in the appearance and structure of the retained fœtus: "The extent to which the changes occur depends, to a great extent, on the length of time the fœtus has been dead, but they do not admit of our estimating with any degree of accuracy what that time has been."

Dr. McClintock, on the same subject, says: "It is not possible, I believe, to pronounce with any degree of certainty, from the appearance of the ovum, how long it has been carried in utero after being deprived of vitality—that in every case where our opinion is asked for as to the age of an ovum, it is a wise and safe rule to qualify our reply by saying that at the time its vitality *ceased*, it was of such and such an age."

NOTES ON THE USE OF ANTIPYRIN IN FEVERS[1]

BY GEORGE N ACKER, M D,

ONE OF THE ATTENDING PHYSICIANS OF THE CHILDREN'S HOSPITAL, WASHINGTON, D C

I desire to present for consideration some notes on the use of antipyrin in fevers, because during the past summer I have employed the drug in many cases of fever, and had such good results from it in all cases that I have come to regard it as an eminently useful, safe, and quick antipyretic Though of recent origin, it has at once assumed a prominent place as an important medicinal agent, and appears destined to take a high rank as an antithermic remedy It has suddenly and successfully sprung into favor, and as yet has not disappointed those who have used it in a rational manner I am anxious to learn from the experience of those present whether they have observed in their cases any unpleasant effects following its use, for as yet I have not seen any of the bad symptoms which have been attributed to it

The chart of several cases in which I employed the drug in my service at the Children's Hospital will illustrate better than words can express the good effect of the medicine in these cases Dr Kolipinski, the resident physician, to whom I am indebted for the notes, informed me that there were no bad effects following the use of the drug in these children It was given in the first case in 5 grain doses, hourly repeated until 30 grains were given In the second case, a 5-grain dose was given every three hours until 36 grains were taken

Case 1 —Colored male, æt 6 years, hectic fever, the drug was given several times, and each time the temperature was kept down by it This was a tuberculous case in which there was a subnormal morning temperature, and an evening rise to 104° The first day the chart gives

1st Morning temp 97, resp 32, pulse 108, evening temp 98 5, resp 44, pulse 112

2d Morning temp 97, resp 32, pulse 100, evening temp 98 9, resp 40, pulse 110

3d Morning temp 98, resp 30, pulse 100, evening temp 102 2, resp 48, pulse 120

4th Morning temp 98, resp 36, pulse 112, evening temp 102 8, resp 52, pulse 112

5th Morning temp 97, resp 32, pulse 104, evening temp 102, resp 44, pulse 120

6th Morning temp 97, resp 32, pulse 104, evening temp 99, resp 40, pulse 108

7th Morning temp 96,6, resp 36, pulse 107, evening temp 98 6, resp, 28, pulse 100

8th Morning temp 98, resp 40, pulse 126, evening temp 100, resp 44, pulse 128

9th Morning temp 98, resp 40, pulse 112

The drug was given the first and sixth days It had the effect of keeping the temperature down the same evening and several succeeding evenings, and the fever did not ascend so high as before the medicine was given Later on, the drug was again used on account of the high temperature On the evening before the temperature was 102 4 The next day it was morning, 99 2, evening, 99 2

2d day Morning, 97 5, evening, 101

3d Morning, 99 4, evening, 98 6

4th Morning, 98 6, evening, 101

This was repeated each time the temperature became high, with always the same happy effect

Case 2 —White male, æt 6, typhoid fever The drug did not act as well as in the first case, because the doses were not given close enough together to produce a good effect, yet the chart shows that the temperature was favorably influenced by the medicine In this case the temp had been 103 5, resp 24, pulse 140

1st Morning temp 101 5, resp 44, pulse 132, evening temp 102, resp 34, pulse 132

2d Morning temp 98, resp 36, pulse 124, evening temp 102 5, resp 52, pulse 120

3d Morning temp 99 8, resp 48, pulse 132, evening temp 102, resp 32, pulse 116

Thus the antipyrin, given the first day about noon and continued in 5-grain doses every three hours until 30 grains were taken, had the effect of holding the temp several degrees below what it had been before it was administered It was given again in this case with good effect The pulse and respiration records prove that these are not influenced by the medicine, and I may add that this was found to be the case with all the patients on whom it was tried

Recently, in a case of typhoid fever in a man æt 30, colored, I kept the temperature below 100° by the use of the antipyrin It did not have any effect on the evolution of the disease, yet the general symptoms were ameliorated by it In this case, grs lx were given in hourly doses of gr xv During the past summer, I gave it with beneficial effects in several cases of malarial fever One case, male, white, æt 12, had had a high fever with delirium for three days When I first saw him after this attack the temperature and pulse were normal, but the next day the boy had a temperature of 102 5, pulse 120, and was slightly delirious Fearing an attack of the same nature and length as the previous one, I gave him at once gr xv of antipyrin in water, and directed gr xv more to be given in an hour's time He slept most of the day, and awoke in the evening without fever, and was feeling well In this case it did not prevent a return of the disease, but cut short the attack, for I believe that without the drug the child would have had a high fever with delirium for several days, as quinine did not appear to influence the temperature

Jahn and other writers have recorded during the past year splendid results obtained from the use of this drug in puerperal fever and febrile conditions due to operations on the abdominal organs (JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, Vol iii, No 22) Dr Samuel Macknew, in the *Lancet*, Sept 5, 1885, has an article entitled " Notes on Some Cases of Typhoid Fever of a Cerebro Spinal Type, Hyperpyrexia Treated by Antipyrin " In the cases detailed the treatment of high temperature by the use of antipyrin and sulphate of quinine was well contrasted The former, in two doses of gr xxx each, reduced the temperature from about 104° to near normal every time it was administered, whereas sulphate of quinine failed to have any effect, though given in two doses of gr xxx each, two hours apart The tendency to high temperature was well controlled by frequent and regular doses of antipyrin He employed it on 102 occasions in eight cases The sulphate of quinine was the only other febrifuge used, but its use was, however, quickly abandoned when the pronounced superiority of antipyrin in this respect became apparent Among the disadvantages of the use of antipyrin has been, according to some, the fugitive quality of the physiological action of the drug According to Macknew, the effects of a full dose of gr xxx rarely persisted longer than six hours, and in many cases for a shorter period My experience does not bear this out, as I have found that full doses of gr lx, given in hourly doses of gr xv each, will keep the temperature down at least twenty four hours and sometimes longer, and will influence the rise for a few days In many cases the drug is said to produce a rubeoliform or scarlatiniform exanthema Macknew found the latter on the face and neck unaccompanied by any itching or subsequent desquamation Dr Paul Ernst has reported some cases in which a papular eruption followed the use of the drug, but which ran its course, though the medicine was continued He explains this by supposing that the system acquired a tolerance for the drug The eruption was thickest on the body and extremities, the extensor surfaces being more covered than the flexor I have never met with this manifestation of the drug in my cases, nor have I noticed nausea or vomiting, which are said to be caused by it In some of my cases,I have observed the diaphoretic action of the medicine, but it has never been so profuse as to weaken the patient or give rise to any trouble In a case of typhoid fever this appeared to do good, as it relieved the patient from the dry condition of the skin from which he had previously suffered

---

[1] Read before the Medical Society of the District of Columbia October 14 1885

May (*Deutsche Med Woch*, 1885) reports a case of collapse after the use of antipyrin Burrs (*Lancet*, February, 1885) has reported a death following the exhibition of the medicine Only gr xlv were administered, in two doses of gr xxx and xv at short intervals The fever fell from 103 5 to normal, and then collapse ensued from which the patient never rallied At the autopsy the brain, membranes and lungs were found congested The spleen was enlarged and softened, with a number of infarcts Infarcts were also found in the kidneys He states that there can be no question—though the patient was undoubtedly very ill—but that the extreme depression accompanying the fall of temperature was directly due to the action of the drug In other cases it had acted well, holding the fever in check ten to twenty hours

Prof Penzoldt directs that in children as many decigrammes be given as the child is years old, repeated three times at intervals of one hour If this dose does not suffice for the production of a decided effect, then it must be increased decigramme by decigramme In adults, most writers have stated that they had given 60 grs, divided in two doses of gr xxx each I have found it best to give gr lx, divided in four doses of gr xv each, and give them at intervals of an hour This has had a decided and continuous effect on the temperature

We must greet with pleasure the advent of any drug that will lower the temperature in typhoid and tuberculous fevers, and if we have found in antipyrin this long sought for agent—as I think we have—it will be a great boon to patients suffering from these diseases It is certain that we cannot resort in many cases of typhoid fever to the cold treatment (baths, pack, etc), and I do not think that it is always advisable to do so, for besides the prejudice of the American people against this method of treatment, I am not certain but that in certain cases it does harm Large doses of sulphate of quinine, which has been used in these cases to reduce the temperature, do not always have the wished for effect, but, on the contrary, sometimes do harm by increasing the head symptoms Antipyrin, on the other hand, relieves the delirium and disturbed sensorium This is also the best remedy we have to reduce the hectic fevers in tuberculous patients In fact, it is about the only drug that will certainly keep down the temperature in these cases

It is true that the natural evolution of diseases is not arrested by antipyrin, yet, by controlling the hyperpyrexia, and consequently the degenerative and wasting processes due to it, the drug is invaluable, and will doubtless in the future take an important part in the pathogenetic and expectant method of treatment of the zymotic diseases

MEDICAL PROGRESS

MATERIA MEDICA AND THERAPEUTICS

Styptic or Hæmostatic Ether —Dr B Ward Richardson gives us an ether which, while checking hæmorrhage by cold, overcomes the subsequent relaxation of the vessels by its constringing action He has had prepared a solution of absolute ether, having a boiling point of 95° Fah, charged to saturation at a low temperature with tannin, and afterwards treated with collodion, a little short of saturation The compound ran easily through the spray tube without blocking, it produced good local anæsthesia, and it possessed an agreeable odor He tested it in a few drachms of blood which had been deprived of its fibrin by whipping, and then left for two days exposed to the air until it underwent partial decomposition The blood was placed in a saucer at the temperature of the body, the spray made to play upon it, and in five seconds the whole mass of blood was so thoroughly solidified that the saucer could be turned upside down without any escape of fluid The blood was also deodorized, and remained inodorous for ten days

When styptic spray is directed on an open bleeding, living surface, the primary effects are those produced by the cold—namely, the condensation and whitening of the tissues If blood be flowing, it solidifies, and when the parts relax, new blood that may ooze up enters the solid blood as though it were a sponge, the coagulation soon stopping further flow

The elements of this process are three in number

1 The immediate constringent effects of cold on the blood-vessels

2 The styptic action of the solution on the fibrin and albumen of the blood

3 The extreme mechanical fineness of distribution of the fluid on the bleeding surface

Styptic ether can also be applied to the hæmorrhagic surface after the extraction of a tooth, for hæmorrhage from cancerous disease of the uterus or other cause, and in cases of hæmorrhage from piles —*The Asclepiad*, July, 1885

MEDICINE

INTRA-CAPSULAR INJECTION OF WATER IN CATARACT-EXTRACTION —At the meeting of the Ophthalmological Society of Great Britain, on October 15, DR W A MCKEOWN read a paper on this subject His method consisted essentially in the substitution in the operation of extraction of a washing out of the cortex for the pressing, rubbing, and scooping out His method of operating was as follows He made the small flap section of the cornea above with puncture and counter puncture in the sclero corneal margin, and cut out about half a line from the corneal margin He always performed iridectomy After lacerating the capsule freely, and expelling the lens if any cortex were left behind, he introduced a perfectly clean "scoop syringe" well within the capsule, and injected gently distilled water of the temperature of about 100° Fahr, making gentle motion at the same time with the scoop to facilitate removal He had now used the scoop syringe in all thirty-nine times In one case only was there irido choroiditis, with complete closure of the pupil, good perception of light was retained In another case, there was most insidious iritis, beginning after the patient's discharge from the hospital, it went on to closure of the pupil, but there was a good prospect from iridectomy In the case of a syphilitic subject, there was a severe iritis arrested by artificial leeching and mercurial inunction In no case was there suppuration of the eye or of the cornea, and in no instance was there escape of vitreous humor from the use of the syringe Even in two cases of traumatic cataract, the syringe was used with advantage, notwithstanding the previous escape of vitreous humor In a few cases some iritic adhesions formed, as commonly occured in ordinary cataract operations, but caused no pain or diminution of vision In twelve cases, the cataracts were unripe, and in several the cortex was very sticky In the last thirty cases, he had had only one inflammation, and that was in the case of the syphilitic subject above referred to There were two cautions to observe, first, after iridectomy, to get the blood out of the anterior chamber as quickly as possible, secondly, to be careful to introduce the scoop within the capsule He did not believe in operating against time, but there could be no doubt that the quicker the work could be done and the eye bandaged, the better He timed the duration of the last eleven operations from the introduction of the speculum to the application of the bandage It varied from six to fifteen minutes, the average being about nine minutes The operations were all done without chloroform, and some of the patients were restless The conclusions which he thought he might draw from his own experience were (1) that the judicious injection of water within the capsule of the lens was innocuous, (2) that it was not liable to cause loss of vitreous humor, (3) that it was advantageous both in ripe and unripe cataracts, (4) that it shortened the average duration of cataract operations, and (5) that it was a most efficient means of clearing the wound —Mr McHardy said that the method might be used for ripening immature cataract, and to facilitate the removal of cortex at the time of extraction The method of trituration as advocated by Foster, the extraction being preceded by preliminary iridectomy, had been, in his hands, followed by no disagreeable results He had, however, noticed a loss of vitreous, which he was not accustomed to see in lenses that had spontaneously matured Posterior synechiæ could be broken down at the time of operation There might be danger and difficulty in getting the nozzle of the syringe within the capsule The capacity or water in removing the cortex was well known, and if he had to deal with a "sticky" cortex, he usually took the speculum out, closed the lids, and allowed the aqueous humor to be secreted into the open capsule, then, manipulating with the spoon, it was not at all difficult to remove the cortex after the aqueous humor had acted on it —Mr Mackinlay inquired whether Dr McKeown used cocaine He thought the nozzle of the syringe rough, and that it might be improved —Mr Critchett mentioned that M Panas, of Paris, irrigated the anterior chamber in cataract extractions, but the stream was produced by an assistant —Mr Adams Frost asked whether the method could be employed for lamellar cataract It seemed to him to be a sound surgical procedure, and preferable to the use of the scoop or manipulation —Dr McKeown, in reply, said that he did not employ the method in simple cases He had not had any trouble with the instrument The operator should get the instrument in behind some of the cortex of the lens He did not see why it should not be employed in lamellar cataract He now always employed cocaine —*Brit Med Journ*, Oct 24, 1885

APOMORPHINE IN CROUP AND BRONCHITIS —DR STUTZ, of Neuminster, is loud in his praises of apomorphine, subcutaneously injected in diphtheria complicated with croup, and in primary croup itself Of ten of these latter cases, he lost only one, and this he attributes to his not having been called in quickly enough Similar treatment is also very valuable in dyspnœa due to bronchitis He has also been successful in cases of arsenical poisoning in children, and in one where a woman had such severe pharyngitis that she was quite unable either to swallow or speak An apomorphine injection quickly emptied the stomach of pus and mucus, and enabled her both to speak and swallow —*Brit Med Journ*, Oct 17, 1885

SURGERY

ON THE AUSCULTATION SIGNS IN VESSEL-WOUNDS

—The sounds heard with the stethoscope are among the most important that one finds in cases of arterial wound, and WAHL (*Deutsche Zeitschrift für Chirurgie*, Bd XXI, Hft 1), after carefully verified observations and experiments, has come to the following conclusions in reference to them In the first place, he finds that in cases of partial division of the coats of the artery in which the cut is insufficient to allow the blood to escape from the vessel, though it may course for some distance between the coats, a distinct blowing or scraping sound, synchronous with the pulse-beat, is heard most plainly at the injured spot, though it is carried some distance along the coats of the vessel, and can be indistinctly heard a short space on each side of it In most of these cases the pulse can be felt below the place of injury, though the beat is not so forcible as on the sound side When a large vessel has suffered a gunshot or punctured wound, and the escaping blood is quickly brought to a standstill by the formation of a coagulum, a periarterial hæmatoma, which is generally without pulsation, is formed, and the stethoscope reveals a distinct murmur synchronous with the pulse On the other hand, when there is complete division of the artery-tube, the ends of the tube retracting and completely closing it—and in all instances where the continuity of the blood stream is broken, there is no sound to be heard at all, though the diagnosis is made sure by the absence of pulsation in the vessel below the wounded spot If the ends of the completely divided vessel yield to the blood current again, a soundless tumor rapidly forms The only exception to this rule is in cases where, through wound of the companion vein, there is a mingling of the arterial and venous blood streams These observations, he says, are practically valuable from the fact that we can safely determine the condition of matters when the chief symptom, the bleeding, is absent, and can then instantly use means to prevent the secondary hæmorrhage which is so likely to follow

DR VON DURING (*Centralblatt für Chirurgie*, No 16, 1885), cannot fully corroborate two of the results as laid down by Wahl He relates a case of subcoracoid luxation of the humerus where violent attempts at reduction were followed by the rapid formation of a traumatic aneurism of the axillary artery On cutting into the tumor, he found the vessel was completely torn across, the aneurismal sac was formed of layers of blood clot, the axillary remaining uninjured In this case there was a well defined whirring murmur as well as failure of the radial pulse, though the artery was completely severed and the vein intact During's experiments upon animals he thinks, justify him in concluding

1 That in the process of clot-formation the pulsation in the tumor very rapidly vanishes, except where the clot is very yielding in texture

2 That the sound very quickly disappears in cases where, through previous ligature of the vessels, the lumen intima is wounded and thrombosis favored

3 That the lumen of the tube often remains free, that in these cases, as well as in recent hæmatomata, a whirring sound synchronous with the pulse is heard, and that this is often accompanied by pulsation in traumatic aneurism, whilst pulsation may be absent in hæmatoma

He believes that quick retraction and occlusion are not inevitable consequences of the division of a vessel —*Medical Chronicle*, September, 1885

TREATMENT OF NÆVUS BY SODIUM ETHYLATE — DR B W RICHARDSON overcomes the necessity for waiting for the removal of the crust which forms over a nævus after the sodium ethylate has been applied, and which sometimes results in fresh growth beneath, by applying the ethylate very freely at first, adding a second layer of it when all the watery oozing has ceased This causes in three days an extremely firm crust On the third day, while the crust is still firm, instead of removing it, he punctures through it in three or more places with a sharply edged flat needle, and with the needle breaks up the vascular surface beneath freely On withdrawing the needle a few drops of blood exude from the needle points, which blood is taken up with cotton wool, pressing firmly so as to empty the surface entirely of blood Then a little ethylate is applied over the whole surface After four days, if, on pressing the crust, there is evidence still of fluid underneath it, the needle is once more inserted and used as before, but if the scale be flat and firm, it is allowed to remain until it falls off of itself and leaves an even and healthy surface —*The Asclepiad*, July, 1885

OBSTETRICS AND GYNECOLOGY

EXPULSION OF THE FŒTUS IN ARM-PRESENTATION —In a note on this subject MR HERBERT THOMPSON says I believe that the spontaneous expulsion of the fœtus in cases of arm presentation is so rare, that the following case may perhaps be worthy of record The mode of expulsion is well illustrated in Leishman's work on *Midwifery*, in which it is stated that Denman was the first to describe these cases, and was severely called to task by the eminent men of his day for suggesting the possibility of such an occurrence

I was called to Mrs N , in labor with her fourth child The water had broken three days previously On examination, I was unable to decide the nature of the presentation, but could tell that it was neither head or nates On examination again I found the arm hanging out of the vagina up to the shoulder, with very strong expulsive pains I tried to introduce my hand to reach the feet, but the expulsive efforts were so great, that I was obliged to desist I sent for chloroform but the messenger had scarcely left the room, when the patient said the child was coming On looking, I saw to my surprise the nates coming down by the side of the arm Another expulsive pain, and the legs appeared, the case being now resolved into one of ordinary breech presentation The head was easily disengaged, and a dead, but in no way decomposed, child was born, although the mother maintained that she had gone to her full time The child was very small, which probably accounted for the ease with which it went through its acrobatic performance —*British Medical Journal*, Oct 24, 1885

THE PRODUCTION OF FEVER HEAT

We are told by various authors that the heat of fever is due to increased combustion of tissue, or to diminished liberation of heat, or to both together, either of which, theoretically, we might suppose would cause accumulation of heat, and account for the pyrexia Most recent writers upon the general subject of fever content themselves with a statement of the vital changes that commonly accompany increased bodily temperature, with a mention of the theoretical explanations of the causes of the heat, and an acknowledgement that no satisfactory explanation has yet been devised

We know that a destruction of tissue out of proportion to the nutritive matter assimilated occurs, and as a consequence heat is produced While we have, however, more heat evolved from tissue-change in a feverish individual than would be evolved in a healthy person, living upon the same diet, no more tissue-change takes place, and no more heat is evolved, than would have occurred in a healthy man while subsisting on a liberal diet We know also, that there is in fever great prostration, great loss of flesh, of strength, and of energy, not because of so great an increase in combustion or retrogressive change in the tissues, as on account of a cessation of assimilation and repair

It is evident, then, that unless some other factor were present besides the production of heat, we would not find the bodily temperature raised above normal In order to explain the increase of temperature, it is natural to turn to the mechanisms of the body, which manage normally the liberation of heat, for the necessary factor We would expect to find them, in pyrexial states, so acting as to prevent the liberation of heat from the body, and thus contributing to induce its accumulation This is in part true In the earliest stages of many fevers, we find the bodily temperature raised, but the cutaneous capillaries contracted, the skin cold, the limbs shaking, and the teeth chattering in a chill In fact, all the circumstances present are most unfavorable for the elimination of heat, and most favorable for its accumulation Later on, in many cases, the skin is found harsh, although hot In health, heat is eliminated and accumulation prevented, by exhalations of moisture from the skin and lungs And the lack of cutaneous moisture in many cases of fever would point to a probable diminution of the liberation of heat But this fact will not account wholly for the fever, since in very many cases in which the bodily temperature is highest, the skin is bathed in moisture, and every circumstance is favorable to the freest exhalation We can also provoke perspiration by the use of drugs, and yet the fevered state persists

Our hypothetical explanations of fever are, therefore, imperfect and insufficient, and any suggestions that will throw light on this most important pathological change, will be received with interest and pleasure One worthy of thought has been made by Dr W M Ord, in a recent address before the Medical Society of London Recognizing the inadequacy of our present explanations, he attempts to outline another He asks the question, "Is the increment of heat of body in fever due not only to combustion or other disintegrative process thereto allied, but also to the persistence in the form of heat of energy, which should have taken another form?" "Throughout the body we recognize two processes ever going on, the building up of tissues on the one hand, their disintegration on the other, The disintegration of tissues is clearly attended by the liberation of heat This upbuilding presents itself to me as necessarily attended by the consumption or disappearance of heat, which assumes some other form of energy, kinetic or potential" But Dr Ord admits that he can find no experimental evidence to show that heat is used up in the formative processes of the body, to confirm his supposition that the increased temperature of fever is due to the accumulation of heat, which in health is utilized in the process of upbuilding of repair and tissue formation Owing to this lack of existing evidence, he has attempted to create it He noticed that in fruit there were two strongly contrasted processes and stages of development; the stage of growth, when formative processes predominate, and result in the production of cellulose starch, etc , and the stage of ripening, when destructive or retrogressive changes predominate and cause the formation of sugar Fruit, therefore, offered in its two stages of development a good subject for experiments, which might throw light upon the utilization or conversion or destruction of heat in processes of growth Dr Ord used the growing and ripening cucumber for his experiments The fruit grows mostly at its ends If a uniform difference of temperature could be found between the air and the cucumber throughout its length, he argued that it would be due to evaporation simply, but if varying at different points along its length, it must be due to the vital processes taking place in it He conducted his experiments by taking, with the same delicate thermometer, the temperature of the air about the plant, the temperature of water standing beside it, and, by thrusting the thermometer into the fruit, its temperature at different points in its length By these experiments he found that the growing fruit is cooler in all parts than the ripening or cut fruit, and that it is coolest where growth is fastest, namely, at the ends So far as these experiments go, they would confirm Dr Ord's supposition that heat is utilized in processes of growth His experiments were too few, as he admits, to make inferences sure, they are, however, suggestive, and may lead to important results

Without doubt too little attention has been devoted to the study of the causes and consequences of lack of assimilation, of upbuilding and repair, which is as constant and prominent a phenomenon of the fevered state, as is the destruction of tissue, and the increase of temperature

---

In applying these considerations Dr Ord says "I believe that, in the production of fever-heat, there is a first factor of increased oxidation, or combustion, or disintegration, setting free heat," but he does not find this sufficient to account for all the increase of heat observed in pyrexia, and still more in hyperpyrexia The further increment he believes to be furnished by heat going astray in default of correlative change in metabolism Dr Broadbent has formulated the problem thus "If a theory of the febrile process is to be formed, it must be based upon a theory of the relation between the nervous system and the processes of nutrition and oxidation, and especially the latter" Dr Ord further suggests that "in all fever, slight or intense, there is superadded to the combustion which we recognize an influence of the nervous system, a trophic influence, arresting processes in which heat should be transformed, and that the increasing temperature is determined by increase of this inhibitory influence" In speaking of how these speculations may bear upon treatment, he mentions the effect and value of baths, which he considers as moderators, they attract, so to speak, the attention of the nervous system, and draw it off from the dangerous paths in which it sets out "In the treatment of hyperpyrexia, I know of nothing so trustworthy as the bath—cool, cold, or graduated," and of these he prefers the latter

DILATATION OF THE STOMACH IN CHILDREN

PROFESSOR MONCORVO, of Rio de Janeiro, was the first to call attention, in 1883, to the frequency of dilatation of the stomach in children, claiming that it occurs as often, even in young children, as in adults He showed at that time that the affection may be produced in newly-born children, and recent clinical observations have led him to conclude that the dilatation coincides, in almost all cases, with symptoms of gastric catarrh of variable intensity

It is not a little surprising, however, that dilatation of the stomach in very young children is not, so far as we are aware, referred to by a single author who has written of the diseases of the digestive tract The youngest child reported by Lafage as having dilatation of the stomach was ten years old, and Demme reports a case at six and a half years, which is the youngest reported by any observer other than Moncorvo In fact, Welch, the latest writer on dilatation of the stomach, says that this affection is rare in childhood, but he adds that Kundrat and Widerhofer state that atonic dilatation due to over feeding, and particulary to rachitis, is not infrequent in children—which coincides with Moncorvo's observations Moncorvo finds that defective feeding is always a preceding factor in these cases, almost all the children were bottle fed, though a very small number were fed on the mixed plan All these cases had undergone the consequences of such feeding—vomiting, colic, and lienteric diarrhœa

Besides the defective nourishment, the other hygienic conditions of these children, as regards dwelling and clothing, were bad, and their physical development was below par In many of these cases, also, there was a history of malarial intoxication, and almost all of them were hereditarily syphilitic It is a well recognized fact that hereditary syphilis, by its dystrophic action on embryonal life, affects all the organs to a greater or less extent, and the digestive apparatus second only to the respiratory It is not difficult, therefore, to account for its causal relation to dilatation of the stomach Severe malarial intoxication, especially such as is quite common in the eastern maritime portion of South America, is often sufficient for the production of dilatation of the stomach. The gastro-intestinal complications and consequences of malaria need not be dwelt on at length to American readers. And while malaria is not given among the predisposing causes of dilatation of the stomach, by setting up a gastric catarrh, its influence as an exciting cause of this catarrh is very well known. Its influence in the causation of gastric ectasia is easily seen, however, when to a malarial condition is added a defective alimentary hygiene.

There are still other cases, says Moncorvo, in which the stomach is mechanically dilated by a constant excess of food when the children are hereditarily syphilitic or enfeebled by other diseases, but these cases are more rare. Lastly, in some cases there are no longer symptoms of dyspepsia or gastritis, and every trace of the cause, save the effect, has disappeared.

The diagnosis of dilation of the stomach in children presents many difficulties, especially when they are very young. Children do not take kindly to physical exploration, so that the diagnostic means recognized as advantageous in adult cases are used with them only with considerable difficulty. *Clapotage*, for example, recognized as a valuable symptom in adults, is obtained with great difficulty in children on account of the energetic contractions of the abdominal walls produced by crying. Another useful means of diagnosis in adult cases, the noise produced by the falling into the stomach of a liquid swallowed "by gulps" while the epigastrium is auscultated, cannot be employed in young children. Moncorvo therefore employs what he terms "plessimetric gastro resonance," which is only a modification of the method of auscultatory percussion. The stomach is previously dilated by giving the child 30 or 60 grammes of a ten per cent solution of tartaric acid, following by a dose of the same quantity of a ten per cent solution of bicarbonate of soda. As soon as the stomach is dilated the bell of a Constantin Paul stethoscope is placed over the centre of the epigastric region, and while he auscultates he suddenly strikes the region with the index and middle fingers of the right hand, commencing near the bell of the stethoscope and going around in concentric circles. The clear resonance heard over the dilated stomach, he says, is heard only over the area corresponding to the stomach.

In concluding his latest and very interesting paper, which is to be found in *União Medico*, of September, 1885, he particularly insists on the etiological relations already spoken of, and again claims that dilatation of the stomach is much more frequent in young children than is to be inferred by reference to published works. He states also that hereditary syphilis and paludism are the predisposing causes in two-thirds of the cases that he has seen. Some of the children are rachitic, but he believes that this affection is often the consequence of hereditary syphilis.

UROGLAUCINE IN THE URINE IN SCARLATINA.

M. Pierre Apéry, of Constantinople, calls attention, in *Les Nouveaux Remedes*, of November 1, 1885, to the presence of uroglaucine (indigo blue) in the urine of scarlet fever patients. In a series of twelve analyses of urine from as many cases of scarlet fever, he found in every case a greater or less quantity of this substance deposited in small blue masses, which are so distinctive that they can scarcely be confounded with any other substance. Neubauer, Vogel, Kletzinsky and Schunck state that uroglaucine and urrhodine (indigo red) are sometimes found in the sediment of urine in cases of cystitis and Bright's disease, but rarely in the urine itself. But, so far as we are aware, Apéry is the first to announce the presence of the former in the urine of scarlet fever.

Uroglaucine may be recognized by filtering the urine and the deposits. The filtrate is then dried, and treated with boiling alcohol. This dissolves the blue materials and is colored violet, and on evaporation the uroglaucine is left with certain other matters, which are washed off with cold water. The uroglaucine is again treated with boiling alcohol, and by careful evaporation the small blue crystals are obtained (Yvon).

Uroglaucine, so named by Heller, is also called urocyanine, by Martin, and indigotine by Schunck. It has the same properties and composition, according to Yvon, as vegetable indigotine. It seems that it must be regarded as a product of the decomposition of indican or uroxanthine, which exists, according to Ritter and some other chemists, in small quantity in normal urine, but is increased in certain pathological states. The action of acids upon it gives rise to urrhodine, uroglaucine and glucose, and curiously enough the same transformation is affected by putrefaction. Casselmann and Strohl were probably the first to point out that indican is increased in diseases of the spinal cord and other grave affections. Hoffman and Ultzmann state, in their "Atlas," that *Harnindigo* (indigotine) is deposited spontaneously in a urine rich in indican, but it is probable that this takes place only after decomposition sets in. Though much work has been done, and much has been written, on the subject of urine pigments, it is still involved in much confusion and obscurity. Even the light thrown on the subject by the most recent and best authorities is far from complete as to the nature and origin of these coloring matters

It need scarcely be said that if Apéry's discovery be confirmed by other observers, it will be an important addition to our means of diagnosticating scarlet fever, which often varies so much in its symptomatology in different cases and epidemics that peculiar difficulties are sometimes presented in recognizing it It is to be regretted, however, that Apéry does not indicate the period in the course of the disease at which uroglaucine first makes its appearance in the urine, and whether it is absent in those affections from which scarlatina is to be diagnosticated It is to be hoped that he, or some other observer, will clear up these points

AMERICAN MEDICAL ASSOCIATION—WORK FOR THE NEXT MEETING

The summer vacations having fully passed, and the season favorable for literary and scientific work having returned, we would remind the officers and members of the Association that the time for the next annual meeting is fast approaching The interest and profit of every meeting depends almost entirely upon the degree of attention that is given to the preparation of papers, and the study of questions for discussion in the several Sections The Chairman and Secretary of each Section should actively solicit contributions from members who are eminent in the departments belonging to their respective Sections, and all who intend to prepare and read papers or reports should give early notice of the same to the officers of the Sections and to the Chairman of the Committee of Arrangements, that these officers may have ample time to arrange judiciously the programme of work for each day of the meeting One of the prominent evils, hitherto noticeable at almost every meeting, is the haste and consequently imperfect manner in which papers are prepared This arises, in a great measure, from the writers postponing the commencement of their work until it is so near the time of meeting that they are unable to complete it with proper care Let everyone, therefore, who thinks he has anything worth contributing to the common stock of professional knowledge, commence its preparation now while there is time enough to do it well, instead of waiting for that "more convenient season" which generally never comes

OFFICIAL NOMENCLATURE OF DISEASES —We learn from a circular issued by DR JOHN B HAMILTON, Supervising Surgeon-General of the Marine Hospital Service, that on and after the 1st day of January, 1886, the revised edition of 1885 of the the Provisional Nomenclature of Diseases of the Royal College of Surgeons of London will be used as the official nomenclature for the U S Marine Hospital Service, instead of the former editions

SOCIETY PROCEEDINGS

MASSACHUSETTS MEDICAL SOCIETY—SUFFOLK DISTRICT

SECTION FOR CLINICAL MEDICINE, PATHOLOGY AND HYGIENE

Stated Meeting, October 14, 1885

(Concluded from page 556)

DR F I KNIGHT made some remarks on

RECENT METHODS OF TREATING HAY FEVER

We all know how frequently the sanguine hopes aroused by some new form of treatment of disease prove delusive We read of various suggestions and experiments, but there is a feeling against trying severe and protracted methods of treatment unless there is a reasonable prospect of benefit from such a course.

The history of "hay fever" is generally well known up to the time when it was first associated with the *pollen* period of certain plants There is no longer any question with the majority of observers that the pollen of ragweed and various other pollen producing plants acts in a large proportion of cases as the exciting cause Dr Beard was the first to make an advance in our knowledge of hay fever, which he did by collecting the history of many cases and examining all the circumstances attending the disease in many subjects and various localities His researches led him to the conclusion that hay fever is to be ranked among the neuroses, and is the effect of a general or central disturbance rather than of a localized irritation Dr Daly, of Pittsburg, in 1881 proposed a local irritation as the cause of all the symptoms and advised the removal of the local condition of hypertrophy of the mucous membrane or other tissue by which the usual passages are obstructed This he tried in a series of cases and observed that the disease did not recur in the succeeding seasons Dr Roe, of Rochester, uses the galvano cautery extensively and with great success

DR Sajous, of Philadelphia, considers that any mode of treatment by which an organic change is produced in the substance of the membrane may be followed by more or less complete relief from the disease, due to a modified condition of the anatomical structures at the seat of the local affection He also recognizes the neurotic element of the disease and unites both theories in his conception of the disease The local character of hay fever was strongly maintained by Hack, of Freiburg

Dr Harrison Allen, of Philadelphia, advocated the removal of obstructions, and thought that obstruction would be found in all cases

Mackenzie, of Baltimore, thinks the name "hay fever" objectionable for many reasons, and proposes the new appellation "coryza vasomotoria periodica" for the whole class of cases heretofore known as hay fever, rose cold, June cold, etc. Mackenzie also mentions a case in which reflected irritation from ovarian disease seemed to be a factor in the production of this affection. These observations are the testimony of reliable observers. There is no mistake as to their accuracy, and they go to show the variety of circumstances and diversity of conditions under which this curious disease is met. The more recent ideas in relation to hay fever find expression in the systematic and persistent treatment of the local manifestations or complications of the disease, which has for its object the removal of the obstruction to the patency of the nares, whatever may be the seat, or nature of the obstruction and the cauterization of the sensory areas by means of the galvano cautery carefully avoiding the olfactory region. The cautery, especially if preceded by the application of cocaine, is productive of but moderate local pain and its use has, in many cases, been followed by most gratifying results.

An example is the following case. A patient presented himself to Dr Knight last spring, in whom the disease had recurred each year for seven or eight years, in very severe form, obliging him either to remain in bed or go to Bethlehem. Treatment was commenced by the removal of obstruction on one side, and the free use of the galvano cautery in the anterior part of both nasal fossæ, while the very posterior parts were cauterized by chromic acid. This was deemed advisable on account of the possible danger of exciting inflammation in the middle ear by the use of the galvano cautery. The result was a most notable relief though not complete exemption from the symptoms. Instead of going to bed, or even staying in the house, or going to Bethlehem, the patient was enabled to go about his usual business. He says in a letter, "the nasal symptoms were so much lighter, that instead of constant flow of secretions and much sneezing, as in former years, this year I have only been troubled by working in the sun, or by very warm dry days, when the discharge would be copious for perhaps half the day, with no filling up of the nasal passages to prevent me from breathing through nasal passages at any time. Asthma has troubled me hardly any, a very marked improvement, as it has formerly compelled me to sit up many nights. On the whole I have been able to attend to my business every day, with comparative comfort most days, instead of the complete *prostration* by September 1st, of former years, and catarrhal cough lasting till winter. This year no cough to speak of and no asthma to care for." He also speaks of the complete relief from nasal catarrh during the early summer, which had been previously quite troublesome. Another thorough cauterization, especially in the posterior region, will doubtless be even more successful.

Correspondence with gentlemen who have heretofore spoken most enthusiastically in regard to the use of cautery in these cases, shows that the past season's work confirms them in their belief that at least a large proportion of cases can be cured, or radically relieved in this way. Dr Mackenzie still insists on the importance of specific treatment of the neurosis as well as local treatment of the nose, and Dr Roe still maintains the essentially local nature of the disease and its required treatment. Dr Sajous thinks that superficial cautery, as formerly supposed by him, may not be sufficient in all cases, but that some, especially those with markedly nervous character, may require deep destruction of tissue.

We undoubtedly owe our patients who suffer severely from this disease, a trial of galvano cautery, all serious obstruction having been previously removed.

DR LANGMAID stated that his experience had coincided almost completely with that so clearly described by Dr Knight, and he felt quite in the same way in regard to the disease. It is always important to discover the *cause* before instituting any form of treatment. It is a source of surprise that some practitioners discover such a large number of cases of hay fever. In a large hospital practice in diseases of the throat, there occurred last year but one (probable) case of hay fever. This year thus far, not a single case has appeared in the hospital clinic. In private practice the number of cases is quite considerable, and does not materially differ from the reports of other specialists. The disease is evidently to be regarded as a neurosis, and corresponds in all essential particulars to the observations of Mackenzie and Beard. A simple coryza may reappear periodically, and be produced by some cause which we cannot discover, but this is not necessarily hay fever. In hay fever there is always, either at the time of the attack or previously, obstruction of one or both nostrils, and no method of treatment can result in a permanent cure until this obstruction is removed. This must be done completely and thoroughly in order to be of more than transitory benefit. We are not prepared to say that a person with no obstruction in either nostril cannot have hay fever, but such cases must be extremely rare. The favorite theory of some specialists is that hay fever is due to some irritation of the "*sensitive areas*" within the nostril. These "areas" may be demonstrated by reducing the vascularity of the mucous membrane by means of cocaine, when many vascular points will still be visible. These are the "sensitive areas." They are very numerous and cannot be treated except by very extensive methods.

If the obstructive nostril is to be made patent, the first thing to decide, is the means to be employed for this object. Of all agents at our command, the galvano cautery is undoubtedly the best. The ecraseur, or cold loop, is unquestionably the safer. The chemical caustics, chromic or acetic acids, are not satisfactory. We are not yet prepared to apply so severe an agent as the galvano cautery to the surface of the entire nasal cavity. The present methods of treatment are doubtless better calculated to relieve this distressing malady than those of former years, and will probably be of great service in very many cases, while some will still prove refractory to any known mode of procedure. The galvano cautery is a means too severe to be employed in light or temporary cases. We are not at present inclined to sear the entire nasal mucous membrane in the free interval of a case of slight, or even moderate severity. The whole question of the applicability of galvano caustic treatment to the majority of cases of hay fever is still *sub judice*. In the meantime, we must not lose sight of the neurotic element in the disease; we must look at the general condition of the patient, his constitutional tendencies, etc. Our information will be more advanced by observation of large numbers of cases than by any prescribed plan of treatment. One of the most remarkable phenomena attending the disease is the development of the neurosis at the seashore, and its lack of development at Bethlehem.

Dr. De Blois said that he had seen few cases, but those were very interesting. Last summer he treated one patient by cauterizing the "sensitive areas" by means of chemical caustics, and the more the cautery was applied the greater number of "sensitive areas" were found, until both the operator and the patient were well nigh discouraged. A solution of cocaine was then applied with the happiest result, the relief being absolute. In this case, there was no obstruction previous to the paroxysm, and nothing to remove. After the attack had subsided, the nostril was entirely free from any obstruction or malformation. It is possible that the formation of cicatricial tissue throughout the nasal cavity might prevent hay fever by destroying the normal textures of the nostril.

Dr. F. C. Shattuck remarked that Dr. Langmaid had observed that obstruction of the nostril is almost always present. Is not ordinary coryza usually accompanied by obstruction of the nasal passages, and how does hay fever differ from a similar attack of ordinary nasal catarrh?

Dr. Langmaid responded that sensitiveness of the conjunctiva is a recognized feature of hay fever. There is a notable relief when the obstruction is removed. Given a case of acute catarrh, it is impossible to say whether the case is one of simple coryza or the specific autumnal catarrh.

Dr. Knight remarked that for this reason some writers have suggested another name for cases of undoubted hay fever, that is, for that form of catarrh which depends on the specific irritation produced by a particular cause. Especially irritant in so called hay fever is the pollen of the rag weed. Bethlehem affords immunity to many because this plant does not grow there.

There appears to be an unusual number of cases at present, owing to the fact that certain practitioners have relieved some forms of the disease by the more recent procedures, and as a consequence, many old and incurable cases present themselves and swell the number of actual cases to surprising figures. Cases of spasmodic catarrh are sometimes observed which are excited by unusual causes. A young gentleman who was married last January has had five severe attacks of bronchial asthma which invariably came on suddenly during sexual intercourse, and have been the cause of much suffering. The patient never had asthma before marriage, and never at all excepting that excited when cohabiting with his wife.

Dr. Langmaid stated that he had known patients in the Rangeley region and in Bethlehem to have a paroxysm during or after a south wind.

Dr. Prince stated that one practitioner has reported several cases of inflammation of the middle ear from the extension of the irritation caused by the actual cautery, along the canal of the Eustachian tube.

Dr. J. W. Farlow said that a certain firm of manufacturing druggists had advertised tablets of cocaine for the relief of hay fever, and he had tried the remedy, with the result of a greater degree of irritation than was caused by the hay fever. Cocaine and bismuth diminish the sensitiveness of the membrane to a moderate extent, but they do not alleviate the tendency to sneezing. Cocaine and fuller's earth relieve the distress caused by the exquisite sensitiveness of the mucous membrane, but do not in the least restrain the flow of secretion. Cocaine in solution is quite useless. For the asthmatic distress as well as for reducing the flow of secretion, belladonna is of great service. Acetic acid has been of no service in two cases in which it was carefully applied to the mucous membrane. The actual cautery seems the best agent for most cases. One factor in regard to hay fever seems to be overlooked by the most of those who treat these cases. The susceptibility of the same patient varies from year to year. Dr. Farlow employed the remedy so strongly recommended by the Rev. H. W. Beecher, and the patient escaped hay fever. At a later period, the same treatment was absolutely without avail in the case of same patient. The susceptibility varies according to the general health of the patient. When the general health is bad, the attacks of hay fever are usually severe.

Dr. Knight's experience confirms that of Dr. Farlow in respect to the curative power of cocaine tablets. In one case, the introduction of a single tablet was followed by the most distressing paroxysm of the entire season.

Dr. Farlow added that the cocaine tablets in the mouth afforded great relief to intolerable itching of the roof of the mouth and the palate, and this may contribute to the comfort of the patient.

Dr. Knight remarked that most gratifying results had been observed after the introduction of cocaine into the eye. The pain and lachrymation were quickly and completely relieved.

Dr. Blodgett spoke of a peculiar case which came under his observation, in which very severe attacks of asthma, with complete obstruction of the nares, lachrymation, itching of the mucous membrane, sneezing, and all the other discomforts of typical and severe paroxysmal catarrh, were induced in a young gentleman by drinking champagne. No other cause had ever produced the paroxysms in this patient, and recently the susceptibility to catarrh has become so modified that a moderate quantity of champagne can be drunk without the occurrence of a paroxysm.

Dr. Knight said that he had known of one similar case.

Dr. Edes stated that ipecacuanha is a substance which causes paroxysmal catarrh in some sensitive persons. Dr. Edes himself is made very uncomfortable by inhaling the smallest amount of this drug

Dr Langmaid added that green coffee has a similar effect upon many people, and that grocers are well aware of this peculiar property of coffee and usually seek to keep out of its danger Certain other substances also possess the power of exciting paroxysmal catarrh in those persons who are peculiarly sensitive, or who suffer from a personal idiosyncrasy in respect to these special irritants

MEDICAL SOCIETY OF THE DISTRICT OF COLUMBIA

Stated Meeting, October 14, 1885

The President, W W Johnston, M D,
in the Chair

Dr G N Acker read some

NOTES ON THE USE OF ANTIPYRIN IN FEVERS

(See p 571)

Dr King asked if Dr Acker knew the chemical constituents of antipyrin

Dr Acker had seen the formula, but could not now recall it

Dr S S Adams was glad Dr Acker had brought up this subject, for the profession in this city seem loath to try antipyrin He had been one of the first to use it here, and had been gratified with his experience He first tried it in a child æt 18 months, suffering with pneumonia A high temperature prevailed despite the use of quinine pushed to cinchonism The child was delirious and death seemed imminent At one o'clock in the afternoon the temperature was 104 6° F He ordered a solution of antipyrin, two grains to be given every hour until six had been taken At 5 30 the temperature was down to 99 5° F, and the respiration and pulse could be counted, a feat not possible four hours previous At 10 o'clock the temperature began to reascend, and was just as high the next day, but again responded to the same treatment Before the three doses were given a profuse sweating would set in Double catarrhal pneumonia supervened, and the child finally died of exhaustion

The second case, a girl of fifteen, had diphtheria Her temperature was 105° F, and she had been delirious several hours Twenty grains of antipyrin reduced the temperature two degrees, and restored the child to consciousness The next day, however, the delirium and fever were as great as before Antipyrin was not again tried, and the child died He had been called to this patient in an emergency, and the attending physician would not consent to any further use of antipyrin

Dr Magruder had no personal experience with the drug, and had come here this evening to learn about it He had been recently reading in the journals the experiences of others, and they spoke of it with but little favor It seems to have a pernicious effect upon the kidneys, and the poisoning is similar to that of carbolic acid

Dr McArdle had some little experience with antipyrin, and was not favorably impressed with it There was no doubt but that it would reduce temperature, but in many diseases such a reduction is of doubtful necessity, unless the patient is suffering from hyperpyrexia The speaker had recently used antipyrin in a case of typhoid fever, and he and the family were much alarmed at the exhaustion and depression following the use of ten grains of the drug in a child

Dr Marmion decried the use of a drug of which we do not know the chemical constituents

Dr Acker closed the debate by declaring that antipyrin is not a secret remedy, and that the chemical composition is given in the journals He did not agree with Dr McArdle as to the danger of antipyrin Depression due to the disease may sometimes be erroneously attributed to the effect of the drug As to its effect on the kidney, it is eliminated by that organ and a previously diseased kidney may suffer Whilst antipyrin does not have a permanent effect on the temperature, it lowers it gradually from day to day He had found it excellent in tuberculous fevers

Dr S B Lyon reported a case of

RUPTURE OF THE RECTUM AND PROLAPSE OF THE SMALL INTESTINE

(See Journal, Nov 14, p 541)

Dr Schaeffer asked if the rupture was within reach of the patient's finger

Dr Lyon said it was fully six inches beyond the anus He inferred that the patient had pulled down the bowel before inflicting the injury There was thinness of the walls in spots due to traumatism, but there was no evidence of ulceration

Dr Hamilton asked the condition of the rectum at the point of rupture

Dr Lyon said it looked something like a buttonhole The protruding small intestine was gangrenous

CHILD WEIGHING ONE POUND AND A QUARTER AT BIRTH

Dr J F Hartigan presented a child three years and nine months old, weighing eighteen pounds, who at birth weighed only *one pound and a quarter* Dr Brengle, of Winchester, Ill, was the attending physician Three years ago, after the parents' removal to Washington, Dr Hartigan first saw the little girl It weighed between four and five pounds, and has since suffered from several attacks of spurious hydrocephalus, diarrhœa, and dysentery, but now enjoyed good health He was not aware of a parallel case, and wished to make it a matter of record The mother has one other child, six years old, healthy, and well developed, both were born at term

Dr Hartigan also presented recent photographs of a case of

CONGENITAL MALFORMATION OF LEFT KNEE-JOINT, OR ANTERIOR FLEXION OF LEG UPON THE THIGH,

which he exhibited to the Society six years ago The leg and foot could not be moved backwards after the tibia and fibula were in the axis of the femur, but at the child's volition, or with the gentlest pressure, the leg and foot bent forward against the quadriceps, the sole of the foot presenting upwards, the toes pointing into the groin, no indication of a patella could be found The child was under treatment five months, is now nearly seven years old, and it is impossible to tell which limb was deformed The patella is fully developed, and posterior flexion complete

DR HARTIGAN also presented a

SECTION OF FRONTAL BONE SHOWING CONTUSION AND BLOOD EXTRAVASATION INTO THE DIPLOIC STRUCTURE

The patient was a white man 35 years old He was struck with a loaded cane, August 22, 1885 A day or two afterwards he complained of deafness, confusion of vision and intellect, dysphagia, and other symptoms of tetanus The first convulsion occurred four days before his death, the twenty second day of the injury The autopsy showed the wound to be practically healed, but the bone underneath was denuded of periosteum, and there was congestion of the brain and its membranes

CHICAGO MEDICAL SOCIETY

Stated Meeting, November 4th, 1885

THE PRESIDENT, C T PARKES, M D, IN THE CHAIR

DR HENRY T BYFORD read a paper on

NERVOUS PAROXYSM, OR SYNCOPE

(See p 566)

DR J H ETHERIDGE asked Dr Byford what he would think of the use of hypodermic injections of digitalis under such circumstances, if any one has ever used it in cases of acute syncope, and why it would not be a good thing to make use of?

DR BYFORD said In these attacks I think digitalis would perhaps hardly be the remedy, for the condition is one of reflex irritation, I think I think it is a case of spasmodic contraction of the heart, and that any nervous symptoms are the result of a contraction of the arterioles of the brain rather than a falling off in the force of the circulation, and that stimulants, such as digitalis, would be liable to do harm This class of cases I have considered really attacks of convulsions, in which consciousness is not lost, sometimes there is a partial loss of consciousness, spasmodic contraction of the diaphragm, the breath almost entirely cut off, and I suppose the same spasmodic condition of the heart, and sometimes, and in some of the cases referred to, there was rigidity of the muscles, one patient trying to throw herself out of bed In real syncope the attacks involve loss of consciousness and relaxation of the muscles Dr N Newkirk has informed me that he formerly treated cases of malaria wherein the onset was marked by such symptoms as have been described These cases, occurring in a malarial district, were characterized by a foul stomach, due to the presence of acrid ingesta Free vomiting, spontaneous or induced nearly always gave relief

DR FRANKLIN H MARTIN read a paper on

PALATABLE THERAPEUTICS

He exhibited specimens of drugs manufactured in the form of pills, capsules, granular salts, elixirs, etc , either tasteless or palatable Dr Martin claimed that many of the greatest improvements in therapeutics have been gleaned from the field of charlatanism Electricity, massage and the "Swedish movement" have been rescued from this domain, and placed upon a legitimate and scientific basis The author claimed that homœopathic medication had three valuable characteristics, palatability, harmlessness, and inexpensiveness to the patients This combination, absolutely without medical merit, accounts for the so called success of homœopathy If we can secure palatability to our remedies, we will do much to overcome the popular aversion to our medicinal preparations Since 1817, when morphia was first isolated as an alkaloid, a great advance has been made in discovering the active principles of drugs Of the alkaloids there have now been discovered twenty two, with actions similar to the parent drugs They are manufactured in pill form, and are more easy of administration than the disagreeable preparations from the crude drugs Twenty glucosides have been similarly isolated and manufactured While this branch of pharmaceutical chemistry is yet in its infancy, we can confidently look forward to the day when the active principles of all the organic drugs will have been discovered, isolated, and manufactured into palatable preparations To day, the salts of various metals, solid extracts, the bromides and iodides, chloral hydrates and the oils can all be administered in capsules Dr Martin claimed to be the first to suggest the enclosing in capsules solutions of chloral in oil We can summarize the means by which we can make drugs palatable as follows The administration of alkaloids, solid extracts, crude drugs of small bulk, and various salts, in capsules or gelatine or sugar coated pills the administration of glucosides and neutral principles in gelatine or sugar coated granules, the administration of tasteless liquids in water, the administration of oils, oleo resins, oleates and drugs soluble in oil in soft elastic gelatine capsules, and the administration of medicines by the hypodermic syringe, suppositories and inunctions

DR J J M ANGLAR said that the object of the paper was certainly commendable He thought the latter part of the paper is valuable, where is urged upon us the necessity of discarding these nauseating remedies and availing ourselves of the science of chemistry, and we should take the admonition to ourselves

DR R TILLEY thought that few experienced men would dare to give iodide of potassium in large doses in capsules He always recommends large quantities of water to be taken in connection with iodide of potassium With reference to arsenic and antimony, we are told they can be administered in solutions in teaspoonful doses We all know that, but he questioned whether it is desirable He has always recommended the administration of arsenic in large quantities of water, and also tartar emetic As to the administration of permanganate of potassium in capsule form, he has known it to be so administered in two or three cases, with very severe pain attending the administration, but he has never administered it in that way himself

Dr. J. H. Etheridge said that he thought the paper very timely, it was full of a great many good points, but he thought there is an objection to the administration of concentrated remedies, especially these alkaloids, in gelatine covers and sugar-coated pills. It sometimes happens that after they have been administered they do not dissolve, and then we get a terrific effect by a half dozen dissolving at once, and in some cases they do not dissolve at all. He recalled a case in which it was decided to give a child thirty-five grains of quinine, seven capsules were administered and three of them passed the rectum untouched. They may not always promptly dissolve, and the consequence is we run a very great risk of injuring our patients.

Dr. A. H. Foster thought it time that we should begin giving medicine more palatably by giving it in smaller doses, and we will often get a primary and not a secondary effect from our remedies, and will not get that terrible perturbation that we would if we gave large doses. The point is, that we can and do have to study the palatability of our remedies. Another point is, that we have learned to simplify our remedies.

Dr. D. A. K. Steele said that in reference to some of the objections that may be urged against palatable remedies, the objection to pills is their insolubility, the fact that they pass through the alimentary canals unchanged. He has repeatedly found them undissolved, he has found that in administering quinine in that form he did not get the desired result. He thought the author made a mistake in giving too little credit to our pharmacists for the advances made in pharmacy in late years, and that the essential point of the paper is the fact that it impresses upon us the importance of giving less medicine and of giving it in a more palatable form.

Dr. R. Tilley said that Dr. Foster seemed to imply that we get our tendency to give small doses from the homœpaths. I take the opportunity of saying that in the large hospitals in Paris and London, they have placed patients with acute affections side by side, and to the one they have given all the medicine they have thought necessary, and to the other they have given careful attention and nursing, with the suggestions a practical physician would give, and there has been practically no difference in the result in the two classes of cases. Experience has taught us to give in certain cases, or in many cases, simply a teaspoonful of water occasionally and that is very important, especially in children, a teaspoon of water is frequently all that the child needs, although few people seem to realize the fact.

Dr. Doering objected to crediting homœpathy with what science and chemistry has accomplished. Take the alkaloids, almost all have been discovered in Germany, where homœopathy cannot live at all—where they have not a single chair in any university. Palatable medicines are simply the natural result of the advance of the science of medicine, chemistry and pharmacy.

Dr. C. T. Parkes recalled one case which illustrates the fact that palatable medicines are not always innocent and harmless. He was called to make a post-mortem examination on a boy 6 years old. Upon opening the abdomen he found in the abdominal cavity a round mass, and upon examination of this round mass it was found to be a sugar coated quinine pill. These were also found in the vermiform appendix and had ulcerated through into the abdominal cavity.

Dr. F. H. Martin closed the discussion by saying that in regard to the iodide of potassium, Dr. Tilley mentioned that he always gives iodide of potassium diluted in large quantities of water. When I was considering iodide of potash, I recalled the experience that I had myself in administering it. I diluted the drug after getting it into the stomach, that is, I gave the patient water after he swallowed the capsule, and he experienced no trouble. In regard to permanganate of potash, it is not necessary to give it in capsules—the oleate of manganese can be used by inunction, or the permanganate of potash be given in distilled water. In regard to the solubility of these pills, any of the best pills will dissolve in water in such a way that the remedies will become free in three minutes. If a capsule or pill of morphine be put in cold water, you can taste the morphia after it has been in the water not longer than two minutes, and you can readily see that by putting the pill into the stomach the gastric fluid, the temperature, and the muscular action, would soon cause its solution. In regard to quinine pills, some time ago I believe that medicine was put up with sulphuric acid, and it lost strength and became almost inert, but now they put quinine up in excipients that will dissolve readily, and also, loosely in flexible capsules.

LETTER FROM PARIS.

(FROM OUR OWN CORRESPONDENT.)

Does an Opacified Lens ever Recover Transparency?—Cure of Cataract—Medical Treatment of Cataract—Eye-dressings after Cataract-Operations—Removal of a Mesenteric Lipoma.

Since the remotest period of medical history up to the present time the question as to whether a crystalline lens opacified can ever resume its transparency, and whether it is possible to cure a cataract by medicinal means, has occupied the attention of medical men. In a very interesting paper on the medical treatment of cataract, Dr. Galezowski replies to the question in the following terms: "The fibres of the crystalline lens become opaque only because they had undergone the process of degeneration as much in their envelope as in their contents, and it is consequently impossible that the lens should resume its former vitality and transparency." The resolution of an opaque lens has sometimes been observed, but this is effected only by the softening and the dissolution or absorption of the crystalline fibres, and the disappearance of the lens itself. The spontaneous cure of cataracts by luxation is not rare, numerous examples have been recorded in works on the subject. Sometimes it is the result of a blow on the head, or on the orbit, sometimes it may proceed from a fall from a height, or it may happen without any appreciable cause In all these cases, the cataractous lens is luxated, its ligament is ruptured, and the cataract falls into the vitreous body This spontaneous depression of the cataract may sometimes be really salutary and persistent, as are often persistent and durable as regards results, the operations for cataract by depression

Apropos of this subject, the late Dr Desmarres, the well-known oculist, relates the following case in one of his works "A pious old lady was affected with cataract in both eyes, but would not submit to an operation She could hardly see to conduct herself, when one day in prostrating herself before an altar in a church, she suddenly recovered her sight 'It is a true miracle,' she cried" The cataract was luxated and Desmarres, on examining the eyes, was convinced of the fact But the spontaneous luxation of the crystalline lens is a simple accident, and no one can count upon it for a cure Moreover, the depression of a crystalline lens may be followed by loss of vision, either immediately or later on, as this quite frequently happens in operations for cataract by depression

The medical treatment for cataract may have for its object to dissolve a cataract, either in dissolving it completely or in arresting its progress and evolution, but as has been shown that this is simply impossible, and all that has been related about the success of such treatment emanates generally from quacks or from practitioners who have faith in their particular nostrums, it must therefore be admitted that we possess no means to arrest the progress of cataract, and still less to dissolve it The only resource we have at our disposal against cataract is, surgical operation

If we are powerless to cure spontaneous cortical cataracts of a constitutional character, we cannot do otherwise than make exceptions in favor of cataracts of traumatic origin In general, traumatic cataracts require the most energetic and at the same time the most careful treatment, particularly during the first few days after the accident Should the cornea, iris, and crystalline lens be wounded, and if the iris protrudes into the wound of the cornea, the former will have to be excised It is here that the repeated application of leeches to the temple will be found most useful, after which the alternate instillation of eserine and atropine drops may be employed with advantage, administering at the same time mercury internally and externally If the wound of the capsule be healed, and the lens remain transparent, the application of atropine or the effecting of a simple artificial pupil, the vision may be completely reestablished without its being necessary to extract the cataract Traumatic cataracts may, however, develop with such rapidity that surgical interference will become indispensable, if the inflammatory accidents are not arrested by an energetic antiphlogistic treatment

In connection with the treatment of cataract I may mention that the same author lately read a note at the Academy of Medicine, on a plan adopted by him for dressing the eye after operations for cataract He reminded the Academy that about three years ago, he was the first to condemn the German method of extracting cataract, and to revert to the principles of the French school, that is to say, to the operation without iridectomy This mode of operation gave him excellent results, and he had no doubt but that it will soon become generally adopted But the author suggested that the success of the operation depended particularly upon the dressing employed after the operation, as suppuration of the cornea, which sometimes occurs, results from the infection of the wound in contact with the tears, which contain microbes To prevent this contact and to maintain the coaptation of the wound, Dr Galezowski covers the latter with large round pieces of adhesive gelatine combined with cocaine and corrosive sublimate This preparation dissolves the tears only at the end of eight or fourteen hours, according to its thickness, which permits the wound to heal by the first intention Twenty-four hours after, no trace whatever of the gelatine is found in the eye, and all danger of infection of the wound is removed

At the same meeting of the Academy of Medicine, Terrillon presented a patient from whom he had removed an abdominal tumor which gave the abdomen a circumference of 130 centimetres After the operation of laparotomy it was discovered that the tumor was an enormous lipoma included in the mesentery This lipoma was enucleated, which occupied one hour and a half, and the tumor was found to weigh fifty-seven pounds The blood vessels were tied, the abdomen was sutured, and the patient sent to his bed The operation succeeded very well, and the case progressed favorably, no peritoneal reaction, or any other bad symptom, having taken place

LETTER FROM PHILDELPHIA

(FROM OUR OWN CORRESPONDENT)

The College of Physicians—Treatment of Hay Fever—Treatment of Sunstroke—The Academy of Surgery—Hydronaphthol—Substitute for "Buried Sutures"—Instrument for Fractured Patella—Case of Cholecystotomy—Laparotomy—Semi-Annual Meeting of the Pathological Society—Curious Picture of first Ovariotomy in Hong-Kong—The Code

Since my last letter we have had a number of interesting medical discussions in this city One of them was before the College of Physicians, where Dr Da Costa read a paper on the treatment of hay fever by cocaine The result of his experience is, that cocaine is a valuable addition to our means of treating this troublesome affection, but that its effect is palliative, not curative In the discussion which followed, Dr Harrison Allen explained the varying susceptibility to improvement on the part of different individuals by a peculiarity of the erectile tissue of the nose Thus, cocaine cannot be expected to give relief in the hay fever of persons who have little erectile property in the mucous membrane of the nose, while it will give relief in cases in which the erectile property is largely concerned in the trouble, which is in the majority of the cases Dr H C Wood called attention to the investigations of Dr Lyons, of Detroit, who has shown that there are at least two alkaloids in the coca leaf, the absence of one of which may cause failure of the commercial preparations Another valuable paper read was by Dr Orville Horwitz, on the treatment of sunstroke and heat exhaustion This paper gave the result of the treatment of fifteen cases of this disease in the Pennsylvania Hospital during the past summer The essential features of this consisted in the use of cold, and antipyrine for the high temperature, and of musk, ammonia, ether hypodermically, and tincture of digitalis, for the exhaustion Dr Wood remarked that the use of musk was new, while that of antipyrine was not, as it had been used in New York hospitals for this purpose before He said that the ambulance surgeons carried antipyrine with them to give it once, and suggested that they might well cary ice also, since in case of heat stroke it is of so great importance to begin the treatment immediately upon the occurrence of the attack

At the last meeting of the Academy of Surgery, Dr Levis advocated the claims of hydronaphthol as an antiseptic agent He also described a new form of suture to take the place of buried sutures This suture is made by opening a wound wide, and passing a silver wire from the middle line of the bottom into the tissue, passing up toward the edge of the incision, but coming out of the flap inside at a moderate distance from the point at which it entered, so as to take up a mass of the tissue at the bottom of the wound The other end of the wire is threaded on another needle, and passed in a similar manner into and out of the tissue of the other flap The wires are then crossed and each needle is passed through the whole of the opposite flap so as to emerge through the skin at some distance from the edge of the in-incision When drawn upon these sutures approximate the bottom of the wound The ends are not fastened, and a separate suture is used to close the edges of the incision Dr Gross confirmed the good opinion expressed by Dr Levis in regard to this suture, saying that he had used it very successfully

At this meeting Dr Morton showed a most ingenious steel rod, with sliding shoulders attached, which he uses for the cure of fracture of the patella The rod is bored through the two fragments, the shoulders are slipped up until they press the fragments together, and then each is fastened in place by a screw The rod is made in two sections, which screw together in the middle like two pieces of a pocket catheter, so that they can be separated and drawn out at opposite sides, thus avoiding the risk of drawing septic material into the wound, which would be unavoidable if the whole were in one piece The irritation caused by this treatment of fracture of the patella, is insignificant, and it is much preferable to Malgaigne's hooks

At the same meeting of the Academy, Dr Keen reported an operation of cholecystotomy, in which, after having felt fully convinced that he had touched a gall stone with the needle of a hypodermic syringe, it turned out that this could not possibly have been the case, as the gall-bladder was in an unnatural position, lying transversely to the usual position, and far back, being covered by a twisted and peculiarly shaped left lobe, which itself was mistaken for the usual tumor of the gall bladder After cutting down into the abdomen the true relation of the parts was discovered, and the gall stone was found It was so deeply situated and so tightly enclosed in the gall bladder, that it was removed with the greatest difficulty Unfortunately the patient succumbed to the shock of the operation Dr F H Gross exhibited a most interesting specimen of cancer of the transverse and descending colon, which had caused sudden obstruction of the bowels, and for which the abdomen had been opened, naturally only to lead to the discovery that nothing could be done for the patient's relief

At the recent semi annual meeting of the Pathological Society, the address was delivered by Dr J Collins Warren, of Boston, who took for his subject "A comparison of the changes in arteries after ligature and in the ductus arteriosus and umbilical arteries after birth" The lecture was very interesting, and was followed by an entertainment given to Dr Warren, at the St George Hotel

At the last meeting of the College of Physicians, there was presented a most curious picture, purporting to represent the first ovariotomy performed in Hong-Kong The operator was Miss Reifsnyder, a graduate of the Woman's Medical College of this city, and the picture was made by a native artist It represents the patient as seated in a large arm chair, in an open pavilion with a huge pendulous tumor looking like a goitre hanging from the lower part of the sternum Her middle is decently covered with a sort of skirt The operator wears a Derby hat, and a French dress with a long and elaborate train, and she has on high heeled shoes She stands with one foot on the ground and a knee upon the knee of her patient Her knife is an ordinary carver A few Chinese assistants stand around, and there is a very English looking man near a counter, above which is seen a row of shelves on which are bottles and jars, while one of the shelves is filled with skulls and other bones Two most unmistakable Englishmen, with their hats on, stand outside the railing of the pavilion, leaning upon it and looking on at the strange spectacle, evidently mere passers by who have stopped to gratify their curiosity The whole scene seems to lie in the open air and to be of the most public character A printed explanation occupies the open space above the heads of the spectators The whole is a most *naive* representation of the remarkable operation, which I am happy to say proved a success

I will close my letter with a single word, not meant to be controversial, about the Medical Congress When conversing with a distinguished medical man of this city recently, he said to me that he thought it had not been made plain enough to the readers of the JOURNAL that the "New Code" has nothing to do with the attitude which has been assumed here in regard to the Congress This city, where the "Old

Code" may, in a sense, be said to have had its birth, is strongly attached to it And however unnecessary it may be for those who do not need it, it is believed here to be of great value as a bulwark against irregularities to which the frailty of human nature makes many liable The "Old Code" has been too useful to the whole profession in this country to be treated with disrespect in this city, which is nothing if not conservative C W D

COCAINE IN SURGERY—PERSONAL EXPERIENCE OF ITS EFFECTS

To THE EDITOR OF THE JOURNAL

Dear Sir —As a contribution to the aggregate of experience from which the value and application of cocaine is to be determined, I am able to give your readers a statement of its action upon myself while submitting to the removal of a lipoma The tumor was situated on the nape of the neck, and with the outlying integument formed a body about the size of a closed fist Thirty minims of water containing in solution gr j ⅓ of cocaine hydrochlorate were injected at six points over and about the circumference of the growth In addition to this, a mixture of ice and salt was applied for about two minutes after the injection of the cocaine In about the same time the integument exhibited signs of freezing, whereupon the refrigerant was removed and an incision about five inches long was painlessly made

Dr G W Jenkins, of Kilbourn City, Wis, assisted by Drs Wilson and Bryant, of this city, now found much difficulty in defining the tumor, owing to its vascularity, depth, and entire absence of investing membrane These conditions prolonged the operation to fully half an hour, and until a depth of quite two inches was reached (beyond which the cocaine could not be expected to act) there was no sense of the tedious dissection or any pain from the introduction of the fine sutures with which the wound was closed The effects of the ice had of course subsided in a few moments, and at no time could have extended below the integument In two minutes from the injection of the cocaine a decided sense of mental exaltation was realized, quite similar to the incipient stage of systemic anæsthesia from chloroform, and attended with an almost irrepressible tendency to loquaciousness This symptom may have been intensified by the contiguousness of the brain, but did not in the least impair perfect consciousness of all surroundings and necessity of self control

As no evidence equals that of personal experience, our reward for this trial was most satisfactory and convincing, proving that for a large class of minor surgical operations we have in cocaine an agent of inestimable value, and verifying its right to be termed the "angel of anæsthesia"

Independence, Ia, Oct 27, 1885

"WORDS AND THEIR USES

To THE EDITOR OF THE JOURNAL

Dear Sir —In a very excellent editorial on "Latent Talent in the Profession," in your JOURNAL for October 17th, you refer to the use of the word "diagnose" as offensive I beg to call your attention to the fact that Webster gives the words "diagnose" and "diagnosticate" as synonymous, and better authority could hardly be desired It is true that the form "diagnosticate" is more in accord with the Greek *διαγνωστικός*, from which it is derived, but "diagnosis" may as well be considered as derived from *διαγνωσις*, and it certainly has the merit of brevity It would seem to be a most useless piece of work to attempt to check this tendency to brevity in speech in the present age, it certainly would, where the word of *three* syllables can correctly take the place of *five*, as in the present instance

Very sincerely yours,

JAS E PILCHER, M D,
Ass't Surgeon U S Army

Fort Custer, Montana, Oct 30, 1885

[We have received several communications, verbal and written, concerning our objections in the editorial mentioned to "diagnose" for "diagnosticate," "allude" for "mention," "apt" for "likely" or "liable," and even to "cases (or "instances") where," for "cases in which"

1 It must be very evident that "diagnostic" is derived from the first of the Greek substances named above, and the very fact that this adjective ends in *tic*, instead of being *diagnosive*, is an argument in favor of "diagnosticate," since "diagnostic" is used both as an adjective and as the participle of "diagnosticate" We do not object to "diagnose" because it is short, on the contrary, that is the only thing in favor of the word The fact that Webster uses "diagnose" and "diagnosticate" as synonymous amounts to almost nothing in the way of supporting the former as a correct word Webster found that the words were used to express the same idea, and hence incorporated both in his very objectionable Dictionary Dr Robley Dunglison, who was Webster's peer in linguistics—certainly in Greek—gives "diagnose" as *sometimes* used for "diagnosticate," which clearly implies that he considered it objectionable Even if Webster could be regarded an equal authority with Worcester (which is not the case), the fact that he gives "diagnose" and "diagnosticate" as synonymous is offset by the fact that Worcester does not give "diagnose" at all We very seldom find *diagnosiren* used by German writers, though *diagnosticiren* is common In French *diagnoser* is extremely rare, and is not given in the lexicons, while *diagnostiquer* is the correct form In Italian the word is *diagnosticare*, though only recently used, and not generally, if at all, given in the lexicons

We have then Worcester, Dunglison, analogy and etymology against Webster It has been said that usage favors "diagnose" But usage is not sufficient authority for a word which has no right to existence Usage favors the verbs "to ligate" and "to ligature," there is no good authority for these words, and there is for "tie," which will always answer the purpose Common usage does not justify "post mortem" for "post-mortem examinations," "autopsy," or "necropsy," the last two being preferable because shorter

But "post-mortem," and even "a post mortem," are very frequently used by good writers

Webster—and other lexicographers for that matter—gives "hypodermic" as the correct form, and does not even mention "hypodermatic," which is unquestionably correct

2 The use of "allude" for "mention" cannot be justified on any grounds In fact, the words are antonomous, not synonymous To *allude* to a thing is to *suggest* it, to *imply* it, *hint at* it, *refer to* it, to *intimate* it or *insinuate* it, to *mention* is to *specify*, to *demonstrate*, to *declare*, to *state* As has been shown, what is called "common usage" is not an infallible criterion as to correct usage of words "Allude" and "mention are used synonymously by some very excellent writers both in America and in Great Britain In the same way

4 "Apt" is frequently used for "likely" and "liable" "Apt" means *fit*, *apposite*, *clever*, *ready*, *appropriate*, or *prompt* A boy may be apt to learn (have sufficient intelligence and quickness to learn), but so lazy that it is not likely that he will learn An intoxicated person is not only *likely* to fall (will *probably* fall), but is *apt* to fall A good chemist is *apt* to make a good analysis, but if he has no apparatus it is not *likely* that he will make one at all Nor are "likely" and 'liable" synonymous terms "Liable" really means *amenable*, *dependent*, *answerable*, *responsible*, etc And to show how critics will often fall into serious errors, one of our best writers, a good English critic, and a learned man, gives "likely" and "liable" as synonyms of "apt," but refers "liable" to 'amenable," and "likely" to "probable," in his work on "Synonyms and Antonyms," and does not give "apt" under either one! A man who embarks in a business of which he has no knowledge is both *apt* and *likely* to fail, it is *likely* that he will lose money, if he loses money belonging to some other person, which he should not have used, he is *liable* to punishment, and if he cannot make a good defence it is *likely* that he will be punished

4 The use of "cases where" or "instances where" for "cases in which" (or the use of "instance" for "case") in medical writing, and in referring to a *Case* (patient), is so utterly wrong and inexcusable—and so clearly so—that it need not be discussed —Ed]

ASSOCIATION ITEMS

INFORMATION OF IMPORTANCE TO ALL MEMBERS OF THE AMERICAN MEDICAL ASSOCIATION

Membership —Every one who attends an annual meeting of the Association as a delegate pays at that time five dollars, and thenceforward becomes a Permanent Member He continues as such as long as he remains in good standing in the body from which he was originally sent as a delegate As a Permanent Member, he must pay *Five Dollars Annually*, when notified by the Treasurer, whether he attends the meetings of the Association or not Payment of annual dues entitles him to receive the weekly Journal of the Association for one year

Members by Application are such as have not become Permanent Members in the manner above indicated, but apply to the Treasurer for membership, forwarding at the same time to him five dollars and the certificate of the President and Secretary of their State or local society, that they are in good standing in such society They pay five dollars annually thereafter, when notified by the Treasurer Members by application can join the Association at any time, and they receive regularly the weekly Journal

When Dues are Payable —The annual dues from Permanent Members are payable to the Treasurer at the time of the annual meeting of the Association, or immediately thereafter The payment entitles the member to receive the Journal for one year from the following July Payment for 1885, for example, entitles the member to the Journal from July, 1885, to June, 1886, inclusive

As some of the members have not yet forwarded to the Treasurer their dues for 1885, they are urgently requested to do so at an early day Having entered upon another year of membership, they are morally and legally responsible to the Association for the payment of their annual dues, having already received for three months of the new year—1885—the Journal of the Association

Subscriptions to the Journal, from those who are not members of the Association, should be forwarded to the office of publication, 65 Randolph Street, Chicago, and not to the Treasurer, but *all payments of annual dues must be forwarded to the Treasurer, Lock Box 1274, Philadelphia*

Deaths —When a member of the Association, who is in regular receipt of the Journal, dies, his family or other representatives are requested to inform the Treasurer at once of the fact

Payment of Dues for Previous Years —As a few members of the Association are still in arrears for payment of dues for 1883 and 1884, they are requested to forward at once to the Treasurer the amounts for which they are indebted to the Association

Transactions of the Association —These annual volumes, thirty-three in number, to 1882 inclusive, may still be obtained, with few exceptions, from the Treasurer, at reduced prices The Index to these volumes will be forwarded on receipt of *One Dollar* An opportunity is thus afforded to complete sets of these valuable publications, or to obtain important papers and works which are daily becoming scarce

Richard J Dunglison, M D , *Treasurer*
Lock Box 1274, Philadelphia, Pa

NINTH INTERNATIONAL MEDICAL CONGRESS, WASHINGTON D C 1887

[The following are some of the more important Rules adopted relating to the preliminary organization of the Congress —Ed]

1 The Congress shall consist of members of the regular profession of medicine, who shall have inscribed their names on the register and shall have taken out their tickets of admission, and of such other

scientific men as the Executive Committee of the Congress may see fit to admit

2 The dues for members of the Congress shall be ten dollars each for members residing in the United States

There shall be no dues for members residing in foreign countries

Each member of the Congress shall be entitled to receive a copy of the "Transactions" for 1887

3 The Congress shall be divided as follows, into seventeen Sections

I General Medicine
II General Surgery
III Military and Naval Surgery
IV Obstetrics
V Gynæcology
VI Therapeutics and Materia Medica
VII Anatomy
VIII Physiology
IX Pathology
X Diseases of Children
XI Ophthalmology
XII Otology and Laryngology
XIII Dermatology and Syphilis
XIV Public and International Hygiene
XV Collective Investigation, Nomenclature, Vital Statistics, and Climatology
XVI Psychological Medicine and Diseases of the Nervous System
XVII Dental and Oral Surgery

4 The General Meetings of the Congress shall be for the transaction of business and for addresses and communications of general scientific interest

* * * * * * * *

8 The official languages of the Congress shall be English, French, and German

In the meetings of the Sections, no member shall be allowed to speak for more than ten minutes, with the exceptions of the readers of papers and those who introduce subjects for discussion, who may each occupy twenty minutes

9 The rules and programmes shall be published in English, French, and German

Each paper and address shall be printed in the "Transactions" in the language in which it was presented, and preliminary abstracts of papers and addresses also shall be printed, each in the language in which it is to be delivered

All discussions shall be printed in English

10 The President of the Congress, the Secretary-General, the Treasurer, the Chairman of the Finance Committee, and the Presidents of the Sections, shall together constitute an Executive Committee of the Congress, which Committee shall direct the business of the Congress, shall authorize all expenditures for the immediate purposes of the Congress, shall supervise and audit the accounts of the Treasurer, and shall fill all vacancies in the offices of the Congress and of the Sections This Committee shall have power to add to its membership, but the total number of members shall not exceed thirty A number equal to one-third of the members of the Committee shall constitute a quorum for the transaction of business

11 The Officers of the Congress shall be a President, Vice-Presidents, a Secretary-General, four Associate Secretaries, one of whom shall be the French Secretary, and one of whom shall be the German Secretary, a Treasurer, and the Chairman of the Finance Committee

12 The officers of each Section shall be a President, Vice-Presidents, Secretaries, and a Council

13 The officers of the Congress and the officers of the Sections shall be nominated to the Congress at the opening of its first session

MISCELLANEOUS.

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT U S ARMY, FROM NOVEMBER 7 1885 TO NOVEMBER 13 1885

Col E I Baily, Surgeon, relieved from duty as attending surgeon, San Francisco, Cal , and ordered for duty as Medical Director, Div of the Pacific and Dept of California

Lt Col Basil Norris, Surgeon, ordered for duty as Medical Director, Dept of the Columbia

Maj J C McKee, Surgeon, ordered for duty as attending surgeon and examiner of recruits, Boston, Mass

Lt Col E P Vollum, Surgeon, ordered for duty as Medical Director, Dept of Texas

Lt Col J R Smith, Surgeon, ordered for duty as attending Surgeon, New York City, N Y

Lt Col R H Alexander, Surgeon, ordered for duty as Medical Director, Dept Arizona (S O 260, A G O, Nov 11, 1885)

Capt John J Kam, Asst Surgeon, ordered for duty as post surgeon, Ft Ringgold, Tex (S O 141, Dept Texas, Nov 4, 1885)

Capt R G Ebert, Asst Surgeon, ordered from Camp Grant, Riverside Park, New York City, to Ft Hamilton, New York Harbor, for duty (S O 237, Dept East, Nov 5, 1885)

First Lieut G E Bushnell, Asst Surgeon, assigned to duty at Camp Grant, Riverside Park, New York City (S O 237, Dept East, Nov 5, 1885)

OFFICIAL LIST OF CHANGES IN THE MEDICAL CORPS OF THE U S NAVY DURING THE WEEK ENDING NOVEMBER 14, 1885

J S Sayre, Asst Surgeon, detached from Naval Hospital, Mare Island, and ordered to the "Omaha"

W S Dixon, Surgeon, detached from Coast Survey Str "Hassler" upon reporting of his relief, P A Surgeon D O Lewis, and wait orders

D O Lewis P A Surgeon, detached from Naval Rendezvous, San Francisco, and ordered to relieve W S Dixon, Str "Hassler"

J S Dungan, Medical Director, ordered to Naval Rendezvous, San Francisco, to relieve P A Surgeon D O Lewis

OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF MEDICAL OFFICERS OF THE U S MARINE HOSPITAL SERVICE FOR THE WEEK ENDED NOVEMBER 14 1885

Wheeler, W A , Passed Asst Surgeon, to proceed to Ontario, Canada, on Special duty Nov 11, 1885

Urquhart, F M , Passed Asst Surgeon, to proceed to Baltimore, Md , with Str "Manhattan," and then rejoin station Nov 12, 1885

THE FUTURE OF THERAPEUTICS

The Annual Address to the Detroit Medical and Library Association[1]

BY DAVID INGLIS, M D,

THE RETIRING PRESIDENT

GENTLEMEN —Another year in the historv of our Association brings us to-night to a point of observation from which we naturally look back to note progress made, and forwards to plan how best to fulfil our coming duties and opportunities In such a retrospect perhaps one of the most striking facts, and one of which our Secretary's interesting statistics make no note, is that during the entire year of active work in the Society there has occurred no instance of animosity or contention between members, but rather we have harmoniously worked together

Therein, I conceive, lies a valuable lesson as to the uses and value of a medical society We are proud to count a membership of ninety-five active members, but prouder to show ninety-five physicians who have put aside personal animosities and united in a common effort for a common good The experience of such a society also demonstrates that much of the ill feeling which arises among medical men can be obliterated if they will but come in contact with one another There is a treasure of philosophy in the statement that "no man is as good as his best deed nor as bad as his worst" Our professional life is, in its nature, one of an unusually personal character, and we are, all of us, in danger of taking too personal a view of events We are too much in danger of judging some professional brother by his worst act It has happened, not once but repeatedly, in this Association, that meeting as we do, in a more general relation, some of us have learned that others are by no means as bad as our worst act had seemed to indicate

On the other hand, such a society just as surely tends to bring out the fact that we are, none of us, fully as good as our best deed This process of friction, while sometimes disagreeable to the subject, is uncommonly salutary, and tends to a higher average of good work In a word, the year's work has brought about an increase of good feeling and promoted many friendships It would be a great gain, to many localities in the State, if working medical societies were formed and existing societies vitalized into more generous life

As part of the retrospect of the past medical year it might be stated, that an amendment in the organization of the State Medical Society has been proposed by which that Society shall be changed into a delegate body It would seem to be a long step in advance as tending to compel the formation of local societies and to raise the value of membership in the State Society The great need of our profession is unity—no other profession allows personal animosity to so weaken its power as does our own

So, we would hold up our Association as a living example, yet modestly withal, for there are others in the same station Indeed, to night it is our great pleasure to welcome, as we do, so many members of our local sister societies It is a pleasant testimony to the growth of friendly feeling that we can thus come together While we each pursue our work in the coming year, let us carry ourselves simply as regiments in the same brigade, each jealous of our own honor, but all engaged in one purpose

To the gentlemen from neighboring cities, as well as the unattached of our own, we give a cordial welcome, and are honored by their presence

In reviewing the past year there is one fact which can well be mentioned with pride, and that is, the number of pathological specimens which have been presented, enough, indeed, to have furnished working material for a good pathological society Such an amount of material indicates increasing thoroughness of scientific investigation on the part of our members, and ought to serve as a reminder that we can, with much advantage, during the coming year, devote more time to pathological discussion It also recalls the fact that a large part of the reported cases met with in the journals are shorn of half their value by the statement "no *post-mortem* was allowed" nothing confirms a diagnosis like a post-mortem examination Sometimes it disproves the diagnosis

In the year's work of the Society, one element has done much to maintain the interest and promote vigorous life, I refer to the plan of having set debates appointed This plan seems to be unusual in medical societies, but its working has proved most successful, there is an unmistakable freedom of expression and criticism, and much is gained by the vigorous discussion of both sides of a question

In a retrospect of the year's work and contemplating it, as we do, with pleasure, I cannot forbear embarrassing our Secretary by a testimony to his unfailing zeal and attributing to him, in greatest measure, our success And our retrospect brings to our minds that which the years unfailingly bring, the gathering of the ripened grain We are all conscious that our work and our efforts are but part of the necessary growth of life, and "the end crowns the work" We ought to look forward pleasantly to the time of its completion, and, indeed, it is with pleasure that we recall how nobility of character in each, crowned lives which, in their short space, were of benefit and pleasure to us and to all whom they influenced Yet the fields look barren in the autumn, and we could wish that Reynolds's cheery voice and good judgment and Pease's hearty good-will to every body were with us yet

---

[1] Delivered on October 4 1885

There are many other things which such a retrospect suggests, but it is to the future I would call your attention What are the duties and opportunities which lie before us? To such a question there arise many answers, but from among them I would dwell upon one

WHAT IS TO BE THE FUTURE OF THERAPEUTICS?

It is obvious that much of the scientific work of the day is done by men who entertain but slight regard for faith in therapeutics, who themselves seem not to possess such a faith, and whose writings and statements of facts are such as to foster skepticism in regard to therapeutic possibilities It can hardly be denied that, as a result of this, there prevails, in certain quarters, a more or less pronounced skepticism, and that among practicing physicians Now, the blame for this state of things does not lie wholly at the door of those pathologists who can conceive of no disease which does not have its origin in some demonstrable lesion, some atrophy or malformation, and who pass over functional diseases with contempt or an apology, but this lack of faith originates, fully as much, from the one-sidedness and the inefficient methods of therapeutical investigation itself It is a good deal here as in religious matters, many people will not join the church on account of the claims of the world, the flesh, and the devil, but about as many more keep out because of the inconsistencies of those who already are church members Now, it behooves us who have faith in therapeutics to mend our ways And, to my mind, the first thing to be done is to more accurately define and establish the *place of action* of our various drugs While it is obviously true that, the body being a whole, general bodily states in many cases give the indication for treatment, yet it is also true that, not only in diseases distinctly local, but also in general systemic diseases, our therapeutical endeavors are directed to localized functions Instances could be given without number, but the mere mention of the fact suffices In anæmia, rheumatism, scrofula, the various fevers, and, indeed, in about all the general diseases, the constant demand upon the physician is to modify the function of one or other organ Herein, I conceive, lies the success of the skilful physician, of many physicians using the same general group of drugs, one will achieve better results than the rest simply by a more accurate judgment of the adaptation of the remedy

This brings us to the consideration of the next thing which ought to be done, namely we should more thoroughly work out the detailed symptoms of each case It is much easier to formulate in our mind certain gross symptoms and, coupling them with certain physical signs, make a diagnosis of a *disease*, than it is to bear in mind, beside the grosser symptoms, the lesser manifestations, the finer shades, and to make the diagnosis thus *A patient in a certain condition* If we hold in our minds the idea of a pneumonia, for instance, we are not far from falling into some routine treatment of pneumonia, but if we have in mind the patient with a process going on which not only, tangibly enough, interferes with the function of respiration, but, just as certainly, with the function of the nervous centres, the digestive, glandular and circulatory organs, and that the danger may make its appearance at any point, we will not only find indications for prognosis in the varying lesser symptoms, but still more important indications for treatment In other words, we have fallen lamentably behind in the study of symptomatology

The most cogent claims which medicine makes to be considered as one of the sciences are based upon the accumulated facts of pathological and physiological research The pathologist, in spite of his therapeutic skepticism has just cause for pride, so, too, has the surgeon Time was when the surgeon barber was held in low esteem, but our surgical brethren not only claim for themselves, but are credited by the laity with the highest place Their claim is based like that of the pathologist, upon accumulated and unquestionable facts

Now it would seem that the only permanent basis for a scientific Therapeusis is to be found in an exact knowledge of two kinds of facts *first*, what is the precise effect of a drug upon the functions of healthy organs, and *secondly*, what is the effect upon organs whose functions are already disordered?

The first class of facts are being accumulated in a gratifying manner by a number of competent investigators, the second class must, in the nature of things, be accumulated by the practitioners in direct contact with the sick Such men as Dr H C Wood, in investigating the first class of facts, pursue a very definite course The drug to be studied is used *alone*, of definite strength, accurate dosage, phenomena observed are recorded with accuracy and verified by many repetitions Suppose that we apply that plan to our purposes as practising therapeutists Is it not evident that it would work a revolution in the methods of practice, and in the place of therapeutics in medical science! It would first do away with complicated prescriptions, it would compel the physician to pay attention to the quality of the drug used, he would ascertain how long it had been kept in stock, the reliability of the manufacturer and the accuracy of the dispenser He would be compelled to note accurately, not in his fallible memory, but in records which could be referred to again, all the variations both in the symptoms existing when the drug was first administered and the modifications of the symptoms *produced by the drug* I do not say after the drug was given, but "produced by the drug," for by this plan we would soon reach that certainty which constitutes a *fact*

It may be replied that all these things are being done already, and I grant that here and there are men who are following out these lines, and who can justly claim to be scientific physicians, but a perusal of the insufficient notes taken by those whose notes become public in connection with reported cases, and a single thought of those who never take notes at all, establishes the fact that general practitioners have not yet fairly taken in hand the problems which general practitioners only can solve On the contrary, there is abundant and painful proof that the profession as a whole is seriously retrograding We have just said that the scientific physician is one who accurately applies his remedies to accurately observed conditions to produce constant results, what shall we say of physicians who prescribe patent medicines!

I do not refer to "Dr Pierce's pleasant purgative pellets," or "Ayer's sarsaparilla," or "Dr Hartley's great South American cure " We all agree in our condemnation of these and their kind, their makers and their makers' methods There may be some virtue in them, probably is, but not knowing their component parts, we cannot tell of their proper uses They are vaunted to cure such a multiplicity of diseases that we at once deny the claim They are advertised in what we consider an obnoxious manner, we will none of them! I hold in my hand some interesting medical literature The first specimen is got up in somewhat startling red type, and is a treatise upon nervous diseases Celerina, I find therein, is of inestimable value in over fifty different diseases It would take too long to mention them all, but a host of letters from the afflicted prove, among other things, that, to say nothing of spermatorrhœa, impotency and allied nervous diseases (?) locomotor ataxia, malignant jaundice and mollities ossium gracefully yield to this compound, which we are told contains in each fluid drachm the equivalent of "five grains each of celery, coca, kola, viburnum and aromatics " The neurologist's occupation is practically gone

Here I hold a volume upon "Aletris Cordial " I do not know what is in aletris cordial, but seventeen diseases acknowledge its sway, and with seventeen gynecological diseases (among which, curiously, is typhoid fever) counted out the gynecologist is left but a stubble field We are not *quite* sure what constitutes "Fellows' Syrup of Hypophosphites," but a beautifully bound series of text books upon "Nervous Diseases," "Pulmonary Diseases," etc , informs us of its remarkable effects in forty-six different diseases

These are great in themselves, but they pale their ineffectual fires before "Dr Hayden's Viburnum Compound " A similar obscurity hangs over the contents of this prescription, and words fail me in giving any adequate account of its virtues Caulo corea, Iodia, Horsford's Acid Phosphates, Listerine, Tongaline, Dyspepsine, Quineptus, Morrholine Ne phrilene, Asthmaticine, these and many more keep our medical journals alive in more ways than one I do not need to go further, the plain and pitiful fact stares us in the face from nine tenths of the medical journals, that the medical profession has allowed itself to become debauched, it has abrogated its function, and it is impossible to draw any line between the nostrums which the people buy and those which many physicians prescribe I add Ayer's and Hostetter's almanacs to the pile, they are, on the whole, rather more modest than some of the others

No, gentlemen, it is high time that we enter our protest and that we, each of us, purge ourselves The present methods are unjust to the people, for they are entitled to scientific therapeutics at our hands, and to just prices for their medicines (That they pay an unjust price, is evident from the fact that one firm engaged in the manufacture of one of these articles, is said to have paid last year, a dividend of 75 per cent on its capital stock) These methods are unjust to our pharmacists, for they cannot conduct legitimate pharmacy at a fair profit These methods are unjust to ourselves, for we are lowering the standard of our professional life

The future of therapeutics will be this The profession will find that using and recommending private and semi private formulæ, as well as the vast array of elixirs of unknown strength and composition, will result in serious detriment to all parties concerned, and self preservation will compel recourse to scientific therapeutics

Let us all begin now

ORIGINAL ARTICLES

THE PHYSIOLOGICAL ACTION OF THE DIFFERENTIAL PNEUMATIC PROCESS ON THE CIRCULATION[1]

BY E TIEGEL, M D ,

OF NEW YORK

A series of physiological investigations, the major part of which has been made only of late years, can so easily be brought into relation with the manner in which Dr Williams' process reacts on the body that one might easily think that the invention of this apparatus was a consequence of these investigations But on the contrary, the current of thought was a completely independent and original one For this very reason it is the more useful and necessary to show that in the pages of theoretical medicine this apparatus, which for a considerable time has stood a number of practical and clinical tests with brilliant results, can be freely proved and its action physiologically deduced To accomplish this, we have to refer to the researches of a series of authors, among whom we shall mention Einbrodt, Quinke, Pfeiffer, Zuntz, Knoll, and Yager

A number of necessary experiments have also been made with the pneumatic cabinet in which I have been assisted by my colleague and associate, Dr W

A de Watteville, of New York, and Mr Joseph Ketchum, of Brooklyn

Before proceeding further, let me present a short description of the instrument and the process

The pneumatic cabinet as at present constructed is of sufficient size to accommodate a patient seated within it In communication with it is a bellows, or cylinder, of such size that when opened to its full capacity it withdraws sufficient air from the interior of the cabinet to produce rarefaction to the extent of, say, one thirtieth of an atmosphere This done, the patient is instructed to place his mouth over the orifice of a flexible breathing tube, and the air from the outside is allowed to flow into his lungs in its effort to replace that which has been withdrawn The extent of this inflow is the amount of his respiratory capacity, plus the pressure of, say, one-thirtieth of an atmosphere Expiration is thereupon effected by the muscular effort required to overcome the increased atmospheric pressure The amount of air respired by this means, and at this degree of rarefaction, is increased by from 20 to 100 per cent, depending largely, of course, on the individual respiratory capacity

In the following discussion I speak only of the process just described, leaving to other investigators to determine the therapeutic scope of the instrument as an aid to respiration by the reverse of the above, and by the ability of the operator to effect complete artificial respiration by inspiratory and expiratory aid, or force synchronous with the normal respiration of the subject

Let us examine what would happen in our body if the heart stopped, and yet the respiration proceeded normally If such a condition could be produced, and life could co exist, we would have without the respiration exactly the same manometrical pressure wherever we measured it In the advent of an inspiration the pressure in the cavities of the plueræ would necessarily increase, the lungs be more aspirated than before, the capillaries more expanded, their volume increased, and a certain quantity of blood from outside the thorax aspirated into it In this case we would get an inspiratory wave in the vascular system Let us call any movement of air or blood, the direction of which is *towards* the thorax, an *inspiratory movement*, and any movement *away* from the thorax an *expiratory movement*, or wave This inspiratory wave may show itself in the veins only, and not in the arteries of the body, because the semilunar valves of the aorta prevent any other movement than the one towards the capillaries of the body Therefore we have an inspiratory depth wave in the venous system In case of a forced inspiration the pressure in the cavities of the pleuræ is 40 mm less than in the atmosphere, and therefore the venous wave would be large

At the end of an ordinary expiration the pressure in the cavity of the pleuræ is only 6 millimeters less than the pressure of the external air During such expiration the pressure therefore increases 34 mm, and the volume of the lung capillaries must correspondingly decrease, and we have now an expiratory wave, which, according to the mechanism of the valves of the heart, must be felt principally in the the arterial system of the body With a forced expiration we can bring the pressure on the alveolar side of the lungs to more than 30 mm mercury above the atmospheric pressure, and thus compress the blood vessels in the thoracic cavity, which naturally must cause a greater positive expiratory wave than the ordinary passive expiration We would thus be able to sustain a sort of circulation by forced respiration even in case the heart stopped This circulation would have the same direction as the real one, produced by the heart Physiologists have for some time cherished the belief that the functions of the heart were not affected by the relations just explained, and that the action of *respiration* or *circulation* would simply be added to the action of the heart This is the reason why they thought that the arterial pressure was greater in expiration than in inspiration But this was fundamentally wrong The first sphygmographical experiments proved that besides undulations of arterial pressure, caused by the pulsation, there exists another system of undulations much slower in movement and with much longer waves It was proved to be isochronous with the respiration, and therefore was supposed to be caused by it It is a system of waves upon which the pulsations are *superimposed* Without closer examination they declared that the ascending portion of the respiratory wave coincided with and was caused by the expiration, and that the descending portion stood in the same relation to inspiration Einbrodt was the first who registered upon one and the same paper, at the same time, both the respiration and the blood-pressure, and thus proved that the ascending branch of the respiratory wave of the blood-pressure corresponds to the inspiration and the descending branch to the expiration But both systems, that of the respiration and that of the respiratory movement of blood-pressure, are temporarily displaced towards each other

In ordinary respiration the blood pressure ascends during inspiration and sinks during expiration But the highest point of each undulation of blood pressure is immediately after the beginning of expiration, and its lowest point immediately after the beginning of inspiration Such is also the case in deep respiration, where the expiration lasts longer than the inspiration It is not noticeable that the succession of pulsations are quicker during inspiration than during expiration If the respiration be very quick and shallow we cannot find a decided influence of the respiration upon circulation If the breathing is deep and slow, if, for instance, the pneumogastric nerves are irritated, we have the same undulations of pressure as in the first case, but their frequency is not affected

In explaining these facts we must keep in view that undoubtedly the expiratory diminution of the thoracic volume is favorable to the transportation of blood out of the thorax, and that the inspiratory enlargement must cause an aspiration of blood, but it is equally sure that these factors are more than compensated by others equally important These must be now examined, and we shall find them to consist in the influence exerted by the respiratory acts upon the celerity with which the blood runs from the right heart through the lungs to the left heart

If we remove the lungs from the thorax and compare the amount of blood which passes through them, both in equal time and under equal pressure, we find that this amount varies according to the condition of the lungs, viz if the latter are collapsed, the amount of blood is greater, if, on the other hand, they have been insufflated from the trachea, the amount will be smaller In the living body, however, the lungs are never expanded by means of such insufflation, but always by the inspiratory movement of the thorax, by means of which the pressure is lowered on the pleural side, and so the air is sucked into the lungs through the trachea But if we intend to imitate this artificially on excised lungs (for which, of course, we need special apparatus), we find that, under otherwise equal conditions, more blood will pass through the lung which has sucked up its air in the manner described

The net of capillaries in the alveoli is so arranged that by the expansion of the lungs their transverse diameters are increased, and therefore the resistance to the flow of blood is diminished This is the reason why the blood will pass rapidly through a lung which has filled its air cells by suction When, however, the lungs are insufflated, they compress the capillaries to the extent of increasing the resistance to the flow of blood We understand now why, during inspiration, more blood passes from the right to the left heart than during expiration In addition, we have during inspiration a lowered pressure in the whole pleural and mediastinal space, and hence over the heart and great vessels inclosed in the thorax This lowered pressure, however, makes itself hardly felt on the left heart with its thick muscular walls, and on the rigid coats of the aorta, but the opposite is the case with the large veins and the right heart, which suck up blood in consequence

In *inspiration*, therefore, the right heart has more blood, and drives it more easily through the lungs A greater quantity of blood will pass into the left heart and aorta, and for this reason the blood pressure will rise in the arterial circulation

There are two ways in which the heart alone can augment the average arterial pressure One is if the pulsations follow each other more quickly, the other is when the amount of blood which is driven into the aorta is increased in each individual pulsation Both ways may coincide under certain circumstances

One phenomenon still remains to be explained It is the retardation which the tops of the respiratory blood pressure waves show in comparison with the tops of the immediate respiratory curves But this apparent exception is indeed the best demonstration of the correctness of our explanation We said The volume of the pulmonary vessels is greater during inspiration than during expiration, hence there must be a change of volume at the beginning of every act of respiration In other words, we shall have a diminution at the beginning of expiration and an increase at the beginning of inspiration The blood which in the former case is displaced from the lungs must flow into the left heart and into the aorta Therefore we have the highest pressure at the commencement of expiration, but immediately afterwards the pressure sinks When, at the beginning of an inspiration, the volume of the pulmonary vessels is augmented, the increase must be filled out with blood, and for a short moment, that is, for one or two pulsations, the left heart gets less blood than before, and the pressure in the aorta sinks to its minimum

Waldenburg, as is well known, devised an apparatus in which it is possible to make a man inhale either compressed or diluted air He was of the opinion that the arterial pressure is increased by the inhalation of compressed air We know now that the experiments which brought him to this opinion do not justify his conclusions He applied a sphygmograph to the radial artery of a man and made him inhale compressed air He now found that the average position of the lever of the sphygmograph was higher than before But this phenomenon is not caused, as Waldenburg believed, by an increase of arterial pressure, it is caused, on the contrary, by an *increase* of the *venous* and a decrease of *arterial pressure* The blood is stemmed in the capillaries and veins, in consequence of which the tissues are swelled, especially those lying beneath the sphygmograph Experiments upon animals prove the correctness of this explanation The animals were prepared in such a manner that the blood pressure could be measured immediately with a manometer The most interesting ones for our purpose are those made by Zuntz He used the apparatus of Waldenburg, which was connected with the trachea of a dog in which the arterial pressure was registered with the kymograph The possible variations were using, (a), compressed or diluted air in, (b), inspiration and expiration The results are the following

1 Expiration *into* compressed air, arterial pressure *sinks*

2 Inspiration *of* diluted air, arterial pressure *rises*

The respiratory undulations were higher in both these cases than ordinarily

3 Inspiration *of* compressed air, arterial pressure *sinks*

4 Expiration *into* diluted air, arterial pressure *rises*

The respiratory undulations were lower in both cases than in ordinary respiration

It is now not necessary to give a detailed explanation why these experiments prove the correctness of our opinion on the influence of respiration upon circulation If, in case 3, the respiration was continued for a long time, the blood pressure finally rose and its respiratory undulations were strongly expressed But this is caused, very probably, by dyspnœa and contraction of the small arteries of the body caused by it In addition to this apparatus of Waldenburg, many other forms of respiratory apparatus based on the same principle have been applied to the human respiratory organs How far they could have reacted on circulation can easily be deduced from the principles we have explained in the foregoing pages, so that further details are unnecessary

Let us now reflect how to arrive at the solution of the following problem *How can we increase the* *arterial blood pressure in the body by means of respiration?* To arrive at this result we must not blow up the lungs, but expand them by suction. In other words, we must enlarge the chest. To enlarge the chest without muscular force we must diminish the air pressure which compresses it. We see that such a manner of reasoning would guide us directly to Dr. Williams's differential process. We have simple means to prove the correctness of our opinion regarding the essential physiological effects of the apparatus upon the human body. It will be interesting to show that the quantity of blood driven out of the chest by the left ventricle is greater when a person is inside the cabinet in reduced atmosphere, and breathes normal air, than if he is outside breathing the normal air. In the latter case, his body and chest walls are submitted to the same air pressure as the air he uses for respiration. At the first glance we are tempted to employ a sphygmograph. But the error committed by Waldenburg warns us not to use this instrument.

Let us suppose the pericardium, with the heart included, was completely rigid and immovable, and there was between its walls and the heart no space at all, or only an incompressible fluid. If now the systole of the left ventricle should squeeze out of the heart 180 ccm. of blood (about its normal capacity), it can only do this if, in the same time, 180 ccm. venous blood return to the heart. But pericardium and thorax are in reality elastic, not rigid, and the 180 ccm. contained in the left ventricle immediately before the contraction, leave the thorax in a fraction of the time of a whole pulsation. But the venous blood which flows from the body into the heart has the time of one whole pulsation to do so. There must, therefore, at the end of every systole exist aspirating forces which influence (a) the venous blood, (b) the air of the lungs, (c) the walls of the thorax, diaphragm, and abdomen. It is only b in which we are interested. Here we can demonstrate an inspiratory movement of the air, caused by every systole, by joining the trachea of an animal with a Marey's tambour (or Marey's diaphragm), and by arresting the respiration for a short time. But also on man this negative pulsation can easily be demonstrated by joining the cavity either of the nose or of the mouth with a manometer containing a few drops of colored water. We now close all openings (mouth and nose), arrest the breathing, and open the glottis. On doing so we notice a leaping or bobbing of the water synchronous with the pulsations. The first half of the wave is an inspiratory one, that is, the first and quick part of the pendular movement is towards *the chest*. The second part of the movement is constantly interrupted with dicrotism, In case the glottis is closed (few men are able to govern their glottis in such a manner as to keep it open when told to stop breathing) the drop makes again an excursion synchronous with *the pulsation, but it is in an* opposite direction. The drop is moved outwards because now the wave of the pulsation fills the arteries of the buccal and nasal cavities during its passage. Hence the volume of these cavities is slightly diminished. We understand now that the movement which we see when the glottis is open is a difference between two antagonistic movements, and that the systolic aspiration of air is in reality more considerable than is indicated by the manometer.

In repeated trials we have compared measures to make sure whether the excursions of the drop are greater after an inspiration inside the cabinet or not. Without exception we obtained the same result, and we found that they are greater during the sojourn in the cabinet, and are therefore an excellent proof that the quantity of blood thrown out of the left heart into the aorta by one pulsation is greater during respiration inside the cabinet than outside. To further prove that the arterial pressure is raised, we must show that the number of pulsations is not essentially decreased by the apparatus. If a man, whether healthy or sick, be put for the first time into the cabinet, and if he experiences for the first time the dilating influence upon his chest, his pulsations show some irregularity, which disappears as he becomes acquainted with the manner of breathing.

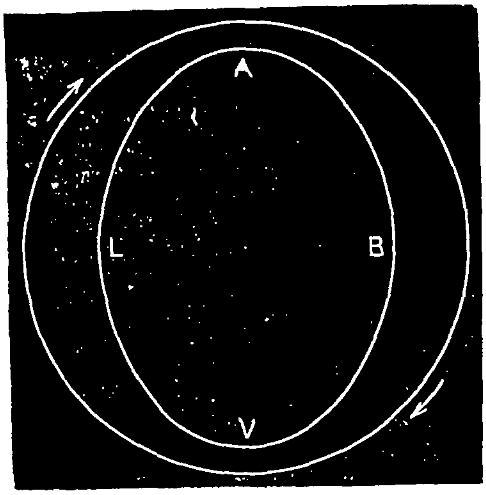
In every case the psychical and physical accommodation is gained after some time, and then we have the general rule that the main number of pulsations taken in one whole minute is greater inside the cabinet than outside, During the inspiratory state of the chest the frequency of pulsation is greater than during the expiratory state, the difference inside the cabinet being much greater than would be the case normally. The following is the outcome of an experiment made which gave, on frequent repetition, the identical results:

Normal breathing outside the cabinet, pulse	70
Inside the cabinet, with diminution of seven tenths inches, average mercurial pressure	
On light (not labored) respiration	88
On full inspiration held	104
On full expiration held (after allowing pulse to quiet down)	60
Ordinary pulse after breathing in the cabinet through the tube and then shutting the stop cock	80

That is arranged:

Normal outside	70
Normal inside	80
During respiration inside	88
On full inspiration	104
On full expiration	60

The changes produced in the pressure and rapidity of blood current by the use of the differential cabinet can be nicely illustrated in the following manner. Suppose we have a walking path or ring (as shown in figure). It is narrow at the two points A and V, and wide at the points B and L. Suppose now a great number of pedestrians have a cause of interest at heart to walk as fast as possible around this path in the same direction as indicated by the arrows. In this case the following conditions obtain. At the two places where the pathway is narrow the crowding will be great. At the places where the way is wide the crowding will be little. Let us call now the broad part, L, the lung capillaries, and the broad part B, the body capillaries. The pedestrians are the blood corpuscles, and the cause of interest which keeps them moving is the heart's pressure. We now intend to widen the portion of the



pathway, L, through the lung-capillaries (as is done in reality by the differential cabinet). This will produce the following changes: 1. The time in which the crowd, otherwise the blood corpuscles, is able to go round the whole circuit once, is shorter, because the road to be traveled over is at one place wider and easier. The rapidity of the blood-current is therefore increased. 2. From V (vena cava) to A (aorta) the crowding—otherwise the blood-pressure—is decreased, because the pathway is wider. 3, In the part extending from A to V the crowding (or blood-pressure) is increased because the crowd (otherwise the blood) gets quicker from V to A than it would do under normal circumstances.

[*Note.*—The comparison which we have used in this instance is only correct when, in every part of the pathway, both before and after the widening of the path mentioned above, the length dimensions (mathematically considered) are very great in proportion to the breadth of the path. If the latter be increased to a considerable amount, then the result of this widening is a lengthening of the road which every blood corpuscle has to travel, therefore a retardation and not an acceleration of the circulation, and besides a lowering of the blood pressure. This may be the case in our own circulation, especially when we have got an extreme dilatation of the large vascular system of the abdomen.]

In regard to the question whether the pressure of the respired air is the same in the alveola as in the trachea, we observed occasionally that the water drop in the heart manometer was drawn violently towards the lungs of the experimenter, when, with a view of watching the drop pulsations during arrested respiration, we opened too soon the stop-cock which shuts off the lungs from the heart manometer during respiration. The air in the alveoli had not yet arrived at the normal atmospheric pressure. But if the experimenter rested for only a few seconds in the inspiratory position, and then began the experiment, the drop always undulated up and down in a certain equilibrium. As a pressure of less than one tenth of a millimetre of mercury would displace or expel the drop, this fact is the surest evidence that even in the farthest alveolus the air pressure can be brought to be the same as the atmosphere, if we rest only a few seconds in the inspiratory position of the chest.

Very interesting and important observations made on patients can be explained by this fact. I mean the arrest of pulmonary hæmorrhages by the application of the cabinet. Indeed, if the pressure in the lung capillaries and its small vessels sinks, those are the very parts from whence these hæmorrhages tend to come, and if the air-pressure remains the same, or is even increased, it is perfectly plain how the hæmorrhage can be stopped.

According to observations made, the succession of pulsations is quicker during inspiration than during expiration, providing the way of breathing is such that any difference can be observed. We made some experiments with the view of determining if inside the cabinet the same relations exist. The experimenter remained for five seconds in inspiration, and and then for five seconds in expiration, and counted his pulse in both cases. In inspiration the frequency of the pulse was considerably greater than in expiration. All professional men who have breathed inside the cabinet agree that the thorax scarcely ever reaches the normal expiratory position, but on the contrary the inspiration surpasses by far the ordinary state, and *if performed slow enough* it reaches the highest standard possible. *Respiration is now performed not with the respiratory air only, but with the complementary plus the respiratory air.* The inhaled and the expired volume of air is considerably greater than in ordinary respiration. Moreover, there is the following important fact. In ordinary respiration, inspiration is the active and expiration the passive act, but inside the cabinet we have the reverse. *Inspiration is passive and expiration active.*

To show objectively that the type of respiration is changed, we made the following experiments. If one breathes through a large tube to which a mercury manometer is attached in such a manner that the lateral pressure of the inspiratory air-current can be measured, we fail to observe any movement in the mercury as long as the tube is wide enough. But the slightest obstacle, as a finger, crossing the opening without closing it, is sufficient to induce the mercury to move, and then we see that the inspiratory excursion of the mercury is greater than the expiratory one. In applying the same disposition to our experiment the experimenter entered the cabinet breathing the normal air through the tube. The mercury showed only an expiratory movement, because now no active aspiration is needed to bring air into the lungs.

In close connection with the question we have discussed thus far, there are others of not much less importance. They regard the exchange of gases inside and outside the cabinet. It cannot be doubted that only special experiments can give a complete certainty in this respect. But we know certain physiological facts, which can be demonstrated, to show what, in all likelihood, will be the state of things. The greater fractions of both the essential gases contained in the blood, that is of O and of CO, are held there in a loose chemical combination. The nature of such a combination causes that the quantity of both gases, contained in a given quantity of blood, can change considerably, but that their tension changes only slightly The tension of O especially is so low that mammals and man can absorb O enough from an atmosphere wherein the tension of this gas is only 50 mm mercury Any given quantity of blood can be saturated with O at this tension, but the process goes on much slower than it would do at a higher tension The higher the tension is the quicker the blood is saturated with O We know that during one respiration the heart makes four pulsations In ordinary circumstances 4+180=720 ccm of blood pass through the lungs during this space of time, and are transformed from the venous into the arterial state

If we should do the same thing outside the body by shaking 720 ccm venous blood with air, we would take much longer time The reason for this is that inside the lungs the blood is spread over an extended surface where it is influenced by air If we fulfil this condition outside the body by making the blood flow along the walls of large glass tubes, through which an air-current runs, the arterialization is performed in a similarly short time There are two factors which favor the oxygenation of blood Firstly, *the increase of contact surface between air and blood*, and secondly, *the increase of the partial pressure or of the tension of O in the air* These factors can replace each other Observations have been made on the population of the Highlands of South America and on other mountaineers Many of them suffer from a peculiar kind of anæmia, which can be cured by sending them to live in low altitudes, best of all at the sea shore From others, otherwise strong and healthy, it is reported that their chest and lung capacity is larger than usual If the blood has to remain a little longer in the lungs, and if it is spread over a greater surface it absorbs the same quantity of O during one respiration that it does at a higher pressure but less surface

Between the limits of human habitation the variations of the contact surface are much more important for the gas exchange in our body than any geographical or meteorological variations of the air pressure It is very likely that a person suffering from a reduction of the respiratory surface, whatever disease it may be caused by, absorbs more oxygen inside the pneumatic cabinet The remarkable effects of the pneumatic process as a general and special tonic, which clinical experience has shown, has been demonstrated in the able and interesting article of Dr H F Williams, in the *Medical Record*, of Jan 17th, 1885 For a healthy man the former statement cannot be made, because the increase in the velocity of the blood movement through the lungs will compensate the possible influence of the increased respiratory surface But such an increase would in most cases be useless by itself The arterial blood of a healthy person is entirely saturated with O, and the influence of the apparatus can be a mechanical one only But in case of a person suffering from a reduction of respiratory surface, we have a different state of matters Physiology teaches us that in dyspnœa caused by the insufficient ventilation of the blood, the arterial pressure increases It is increased not because the quantity of blood contained in the arteries of the body is greater than in the normal (this quantity is, on the contrary, less), but it is increased by a simultaneous contraction of the arterial walls This phenomenon is caused by nerve influence, especially by the accumulated carbonic acid in the blood running through the medulla oblongata and spinal cord If now, in consequence of the influence of the pneumatic cabinet, we get an increase of the contact surface between blood and air, the blood will be better ventilated, and by degrees the cramp-like contraction of the arterial walls will disappear, so that in such a case the apparent effect is contrary to the one produced on normal bodies It will depend on certain circumstances if this decrease will be followed by an increase corresponding to the normal one

The effect just explained, however, can but prove highly useful in any disease where the blood wants more O, and where it is overcharged with CO_2

We finally come to the question concerning the exhalation of carbonic acid This process is, within large limits, independent of the absorption of O as far as mere quantities are concerned But we see that a condition which favors the one, generally also favors the other, and therefore we may suppose that more CO is discharged inside the cabinet than outside, the difference being the greater, the greater the difference of the absorbed quantities of O

In regard to the use of the apparatus in cardiac therapeutics, the physiological conclusion of our argument must be evident, Its use is indicated in every case in which we have a deficient oxygenation of blood, and where the state of the cardiac and arterial walls do not render a sudden dilation dangerous, as, for example, would be the case in fatty or sclerotic degeneration

In closing, I have to render my thanks to my friend and associate, Dr W A de Watteville, of this city, to whose able assistance both in conducting the necessary experiments and in the preparation of the text itself, I am much indebted

EXOPHTHALMIC GOITRE, OR GRAVES' DISEASE

BY J W THOMPSON, M D,
OF ST PAUL MINN

During the past ten years that I have been engaged in the practice of ophthalmic medicine and surgery, I have had the opportunity of seeing a considerable number of cases of exophthalmic goitre The pathogeny and treatment of this remarkable disease are very unsettled and therefore very unsatisfactory With a view of adding something to my limited knowledge of this subject beyond what I was able to gather from its literature, I adopted, in the beginning, the practice of keeping somewhat extended notes of every case of the disease that came under my observation I have selected five typical cases for the subject of this paper, and herewith present the results of my observations to the readers of the Journal

Palpitation of the heart, enlargement of the thyroid gland, and prominence of the eyeballs formed a marked trio of symptoms which were present in all five of the cases selected Each one of these great symptoms occurred in point of time in the order above mentioned The length of time between the occurrence of these symptoms in their regular order was not constant The longer the interval between the heart disturbance and the enlargement of the thyroid gland, the more unyielding was the malady to remedial agents and the more protracted and intense was the suffering of the patient One of the five cases occurred in a male 30 years of age Of the four females the disease occurred in one before the menopause, and in the other three at or about that period The heart palpitation in the male was very distressing several weeks before the other symptoms made their appearance In his case the enlargement of the thyroid was very slight, while the protrusion of the eyeballs was very considerable In all other respects he was healthy and robust and had always enjoyed good health There seemed to be nothing in his individual history that furnished any apparent cause or foundation for the disease Upon investigating his family history, he stated that one member of the family, a brother, had in early youth suffered with "fits" as he termed it A careful inquiry revealed the fact that the "fits" had undoubtedly been epilepsy Possibly this peculiar neurosis manifested itself in the one by epilepsy and in the other by exophthalmic goitre

Of the four cases in females, in three of them, the three characteristic symptoms exophthalmos, goitre and quickening of the heart's action were well marked In the fourth one the enlargement of the thyroid was confined to the left lobe Over the right lobe only a very trifling fulness could be detected The prominence of the eyeballs was very great At times the insertion of the recti muscles could be seen The eyes became very sensitive to the light, and in one a central corneal ulcer formed, which is a complication said by some authors never to occur The severity of the symptoms was so intense that the patient was confined to her bed the greater part of the time for a period of nearly four months Under appropriate treatment the ulcer healed kindly, the patient made a good recovery, and four years afterwards was enjoying good health It is over a year since I lost sight of her, and I am unable to say whether there has been any recurrence of the disease

The general symptoms in all the cases, except the male, were very like Great excitability, anæmia and emaciation were present in a very marked degree The rapid and forcible action of the heart produced a rapid, jerky, trip hammer pulse The carotids throbbed perceptibly and the pulsation of the abdominal aorta could be very distinctly felt In one of the cases I found the pulse as frequent as 170 per minute ! In none of the cases did I find it below 100 There existed in all an extremely intensified self consciousness The most trivial exciting cause produced flushing of the face, great increase of the heart's action, and occasionally much dyspnœa, which in one case, became at times rather alarming In this case however, some of the dyspnœa could be readily attributed to the excessive enlargement of the thyroid The enlarged thyroid increased the size of the neck to such a degree, that the collar she formerly wore was too small by four and one-half inches

Among the general symptoms, besides the palpitation of the heart, goitre and exophthalmos, there were a number of minor symptoms which were more or less present in all the cases, and proved at times annoying and even distressing These were indigestion, hepatic disorder, pains in the extremities, local dropsy, sleeplessness, headache, vertigo, ringing in the ears, nausea, and vomiting after meals, diarrhœa, hæmorrhage from the bowels, nose bleed, night-sweats, and in two of the cases hæmoptysis There was also much irritability of temper The mind became at times very capricious and suspicious, feeble and childish

One of the prevailing theories of the day is that this peculiar disease has its origin in the nerves of organic life From the observations that I have had the opportunity of making, I have become a little skeptical on this point It seems to have been established more by assertion than by proof With a view of throwing some light, if possible, on the correctness or incorrectness of this theory, I made a very careful record of the temperature at stated times in each and every case that came under my observation In each instance I found it above the normal It ranged from 99 to 102 It was usually increased when, from any exciting cause, the action of the heart was accelerated The temperature was always taken on each side of the body at the same time, and it always registered the same, *e g* the corresponding cheeks, the sides of the neck and the axilla The normal difference between the cheeks and the axilla was observed in each instance, with one or two slight exceptions hardly worthy of mention It has been quite conclusively shown by experiment that the ganglionic chains have an action entirely independent of each other If the cervical portion of the ganglionic system be involved, as is claimed, then there would necessarily exist a difference of temperature between the corresponding sides, since it is impossible for both chains to be affected equally in the outset and progress of every case of this disease

Another observation made in relation to the five cases, under consideration that opposes the sympathetic theory, was the prompt response of the iris to the action of light and shade and to atropine The writer does not claim that the phenomena furnished by five typical cases alone could possibly establish a correct theory of the origin of a disease, which furnishes such a multitude of symptoms having such a wide range of deviation He does claim, however, that the sympathetic theory is quite inadequate to explain all the phenomena observed in these cases

Dr Hammond says in his celebrated work on "Diseases of the Nervous System" (page 819, seventh edition) "I am inclined to think that in the present state of our knowledge we are scarcely warranted in locating exophthalmic goitre in the sympathetic nervous system, and that we are justified in regarding it as an affection of the brain and medulla oblongata"

The link that connects this disease to ophthalmology is the local effect it produces upon the eyeballs This is, however, only one of its pathognomonic symptoms Yet, it is a symptom that produces a hideous deformity and has given much notoriety to the disease It gives to the eyes a wild, staring expression They project forwards from the orbits in many instances, so far that the lids cannot close over them entirely The prominence of the globe became so marked in one case that the lids at no time, not even while sleeping, completely covered the cornea A very interesting case of this nature is given in Trosseau's "Clinical Medicine," vol 2, page 178 He says "Dr Pain kindly supplied me with further details of this interesting case Twice in the course of a year there came on such a paroxysmal increase of the exophthalmos, that one of the eyeballs became dislocated as it were" "The eyelids got behind the circumference of the eyeball, which had to be pushed back with a certain amount of force in order to get the lids to come forwards again" This prominence of the eyeballs is due largely to hyperæmia of the orbital cushions, and in the chronic cases, there is undoubtedly some hypertrophy Muller's muscle, which has the power of projecting the eye forwards in health, is supposed by some, to act as one of the projecting factors in this deformity In these extreme cases of prominence, the cornea is constantly exposed to the irritating action of the atmosphere and dust Occasionally, in very chronic cases, the conjunctiva of the upper lids becomes much thickened and the surface of the cornea uneven and vascular

In most of the cases that I have been able to observe carefully, the prominence of both eyes was about equal, and as nearly as I could ascertain occurred simultaneously In many of the cases, however, the extent of the protrusion was rather deceptive The eyelids seemed in some instances to become retracted towards the orbit and favored, as it were their lodgment behind the equator of the eyeball It requires but a small increase in the width of the sclerotic zone to give to the eye the appearance of more prominence than in reality exists In one case I observed a considerable degree of anæsthesia of the cornea, so that the finger could be passed over it gently without producing but slight discomfort to the patient I believe this is the exception and not the rule In the cases of extreme prominence, I found hypermetropia in a much higher degree than I had reason to believe existed before the occurrence of the exophthalmos This was the mechanical result produced by the enlargement of the orbital cushions, which pressed the globe forwards against the resisting lids, and thus resulted a shortening of the autero-posterior axis of the globe

The prognosis in this disease is usually favorable, though when required to express an opinion with reference to any particular case, it is prudent to be guarded, since cases have been known to terminate fatally I never saw but one case having a fatal termination In certain mountainous regions in France, this disease has been known to prevail somewhat as an endemic, and occasionally one has had a fatal termination When death does occur, it is usually the result of general exhaustion and a gradual failure of all the vital forces The victim is by degrees worn out

The treatment is about as unsettled as the etiology The materia medica has been pretty thoroughly ransacked without avail for a specific At one time and another I have employed a variety of treatment Iodine exhibited externally and internally seemed to be attended with more favorable results as far as my experience has gone than any other medicinal agent Yet, in some of the cases, the hygenic and diatetic regulations, together with a change of climate when the circumstances of the patient permitted, had undoubtedly a favorable influence in bringing about a favorable result

I think the only safe plan of treatment is to endeavor to guide the malady to a favorable end To attempt to cut it short by specific measures, seems too much like striking in the dark Many times I believe it is difficult to say whether the patient is cured or got well

St Paul, Oct 25, 1885

ABSCESS OF THE LIVER[1]

BY J W HAYES, M D,

OF MARIANA ARK

I do not propose to enter into an exhaustive discussion of the subject of this paper Nor do I deem it at all necessary, at this time, to deal too minutely with a subject so generally understood by all physicians and surgeons as abscess of the liver But in justification, somewhat, for the present detail I will say this, that the inexperienced upon this subject will find very little to comfort or console them by searching our standard authorities They all state that this is a disease that prevails in Egypt, in the East and West Indies, and one author states that it is occasionally seen in the boatmen of the Mississippi River

---

[1] Read before the State Medical Society of Arkansas April 22 1885

That it does exist, and exists in sufficient abundance, all up and down our Southern water courses and other places where miasma abounds, is a truth that cannot be questioned, and urges every practitioner to ever be on the alert for hepatic abscesses in all cases of chronic disturbances of this organ

When we have a well defined case of abscess of the liver pointing outwardly, we have a case easy of diagnosis, and easily treated, the prognosis of which, with proper treatment, I would always deem favorable But when the abscess is deeply seated, or pointing internally, the diagnosis is especially difficult, the operative treatment tedious and dangerous, and the percentage of deaths far greater To distinguish these latter from encysted, or fatty tumors, from hydatids, and, in fact, to distinguish them at all, the aid of the exploring needle must frequently be called into requisition An intelligent history of the case, however, will reveal enough, with the few physical symptoms that are developed, to almost make certain our diagnosis

But just here we might ask What use have we for the diagnosis? When many of our standard authors say that we must not operate on the deep seated abscesses at all, that they are sure to die, at the same time confessing that the fluid, left to itself without an operation, will some day break internally, and by so doing create a certain death

Bégin, of France, recommends the following operation for deep seated abscesses of the liver Make an incision some two or three inches long upon the most prominent part of the swelling and divide with great caution the layers of the abdominal wall, until the peritoneal linings are reached, raise this carefully with the forceps, nick it and afterwards divide it Upon reaching the surface of the tumor, the operation must be temporarily arrested, the wound filled with lint and dressed, the patient to remain three or four days for adhesions to take place, after which we open into the abscess with reasonable hopes of success Several years ago, the Medico-Surgical Society of Alexandria published the statistics of 123 cases, of which only forty two were operated upon, and eighty one without an operation Of the whole number seventy nine died, in nine the results were not ascertained It is of interest to note that of those not operated upon eighty per cent died, and of those who were operated upon only fifty per cent died It seems to me, with a limited experience and knowledge of the disease, that the death-rate here cited in both classes of cases is higher than it would be in our country

A clinical case of much interest has recently come under my observation, a recital of which may be of interest to others

Case —Saw D M, colored male, about 30 years of age, on March 2, 1885 He gave the following history He had been a deck hand on a steamboat and a cotton picker up and down the Mississippi River for the past two years Had been in bad health for six months, unable for two months to do anything Was now complaining of gnawing pains in the right side, had frequent rigors, was somewhat dropsical, with enormous enlargement of the liver, jaundiced appearance of the eye, etc, making, in my opinion, a well defined case of hepatic abscess To these symptoms were added a dry tongue, tympanites, a temperature of 102°, and other symptoms of a slow and low grade of fever A well defined tumefaction presented itself in the centre of the hepatic region Being a long distance from home, I determined to try the virtue of my lancet, though I was entirely alone with my patient Without unnecessary delay I ran my abscess lancet one inch through the adjacent walls, and to my surprise and disappointment failed to reach an abscess With an exploring needle I found pus and a cavity one inch and a quarter deeper I now rode a half mile to procure a nurse and assistant to carry out directions On returning, I made a free incision, whereupon a stream of sero-purulent fluid began to spurt out with considerable force I pulled out an ordinary bucket, empty, from under his bed, and in twenty minutes it was filled with this fluid, the latter half of which was thick pus All told, there could not have been less than eighteen pints of this fluid I gave him no anæsthetic except a small dose of morphia Left an alterative to be administered, to be followed by quinine

On my arrival next day I found my patient worse Temperature 104 5, some delirium, and symptoms pointing to septic infection The alterative medicine previously administered had acted well, but the aperture in the side had closed up, no drainage had taken place for ten or twelve hours On examination, I failed to find the peritoneal adhesions of the day before to the abdominal wall, and think that some effusion into the peritoneal cavity now took place The adhesions doubtless were of recent date, and not firm enough to resist the pressure of fluid turned in this direction I had previously bandaged the patient to aid drainage of the pus and to favor adhesions in the cavity, when drained His face was badly swollen, and every feature was one of anxiety and distress After carefully probing the wound to the liver, about three and one-half pints of pus were discharged I saw him an hour later, when the swelling of the face had disappeared, as also did all his other unpleasant symptoms I now left him, ordering tr iron gtt xv every four hours, alternating with turpentine emulsion—the latter for the fever symptoms for its diuretic effect, and as a general diffusive stimulant I left him this time confident that about twenty four or forty-eight hours, at the outside, was his probationary period for this life

I saw Mr H (on whose farm the patient lived), three days after my last visit, and was informed that the man was in fine spirits, had a good appetite, and was improving rapidly I sent syrup of hypophosphites, to be taken in conjunction with the other treatment, and directed that the aperture be kept open, and a free drainage induced He was left to nurses of his own race and color, who neglected this important part of the treatment The wound closed, the drainage stopped, and the patient died two days afterwards

This is the fourth case of abscess of the liver that the writer has operated upon, and the only one of the four that died, though one of the other cases was a very delicate and nervous woman about 45 years of age, with bad sanitary and dietetic surroundings The results of the operation in this case suggest the following conclusions

1 Always operate if a reasonable diagnosis is made out

2 Anæsthetics are not necessary in every case for this operation

3 A free incision and a rational treatment warrant a more flattering prognosis, and a larger percentage of recoveries than our standard authorities lay down

MEDICAL PROGRESS.

ANATOMY AND PHYSIOLOGY

The Use of the Fossa at the Lower End of the Fibula—Mr C B Lockwood, in a note on this subject says If the usual text-books be consulted, they will be found to say that the fossa, at the lower end of the fibula, gives attachment to the posterior fasciculus of the external lateral ligament of the ankle-joint Examination of numerous specimens shows that this is only partially true, and that the most important use of the fossa has been over-looked The ligament (posterior fasciculus of the external lateral) is attached into the lowest part of the fossa, quite close to the apex of the external malleolus The upper part of the fossa serves for the reception of the ligament during dorsal extension of the foot

By dorsal extension, is meant a straightening out of the foot upon the leg Many anatomists call this action flexion of the foot, because the flexor muscles of the leg are concerned in its production —*British Medical Journal*, Oct 24, 1885

MATERIA MEDICA AND THERAPEUTICS

Cascara Sagrada—This drug has been recently extensively studied in the service of M Dujardin-Beaumetz, in the Hôpital Cochin Its bark contains several resins, a peculiar crystallizable substance, a fixed and a volatile oil These bodies have not yet received special study, and the drug is given in the form of the powdered bark or the fluid extract Cascara sagrada is an excitant of the abdominal sympathetic, its special action being on the stomach and intestines, it is a purgative, and of considerable value in constipation It has been used in America in intermittent and remittent fevers, but in France it is used solely for its purgative effect

The powdered bark is given in doses of 25–75 centig, and sometimes in doses of 1 gramme The fluid extract is given in doses of 0 50 to 1 gramme The fluid extract is the best preparation On account of its disagreeable taste, the following formula may be used

Fluid extract of cascara	30 grm
Simple syrup	30 "
Peppermint water	30 "
M	

Dose—3 or 4 teaspoonsful a day

In cases of atomy of the stomach, with intestinal inaction or paresis, cascara may be combined with nux vomica

Tincture of nux vomica	2 grm
Fluid extract of cascara	20 "
Simple syrup	15 "
Cherry laurel water	15 "
Distilled water	10 "
M	

Dose—3 or 4 teaspoonsful a day

—*Nouveauz Remedes*, Oct 15, 1885

MEDICINE

Intra-Parenchymatous Injections in Pneumonia—If, says Lepine, an injection of a few centimetres of a very weak aqueous solution of corrosive sublimate be made into the hepatised lung on the third or fourth day of the disease, in three or four places equidistant a few centimetres from one another, and preferably at the periphery of the lesion, with a view of preventing the extension of the disease, the following phenomena are observed 1 At the seat of infection an immediate diminution of the crepitant râles and tubular breath sounds, which are in part replaced by respiratory silence and some larger râles, 2 sometimes, later, a transient exacerbation of the temperature of body, 3 the next day a great improvement in the general condition, and notably a precocious defervescence, and 4 a resolution which, to judge by the persistence of the "souffle," especially in the hepatised parts that have not been treated, takes place very much earlier than would have been the case under ordinary circumstances As to the relative innocuousness of the intra-pulmonary injections in the doses employed (20 to 25 cubic centimetres of 1 in 40,000 solution of bichloride of mercury), when care is taken to keep away from the large vessels at the hilus of the lung, and not to penetrate the lung more than 3 to 4 cm (1⅕ to 1⅗ in), M Lépine urges that he has not lost a single patient and has not had one accident The only inconvenience is the pain, but this is not great, and may be still further relieved by adding morphine to the solution After the introduction of the sharp needle, and before the syringe is fitted on, a few drops of blood are allowed to escape, the injection must not be delayed or the needle will become plugged When the needle is inserted into healthy lung or into tuberculous lung it does not as a rule yield blood In the healthy lung such injections produce sufficiently defined lesions Experiments on the lungs of healthy dogs showed that at the site of injection of a rather stronger solution than that mentioned above, there was a circumscribed and indurated area, which was made of blood and congestive œdema The lesions were less marked with the 1 in 40,000 solution.—*Lancet*, Sept 5, 1885

THE

Journal of the American Medical Association

PUBLISHED WEEKLY.

THE EDITOR OF THIS JOURNAL would be glad to receive any items of general interest in regard to local events or matters that it is desirable to call to the attention of the profession. Letters written for publication or containing items of information should be accompanied by the writer's full name and address, although not necessarily to be published. All communications in regard to editorial work should be addressed to the Editor.

SUBSCRIPTION PRICE, INCLUDING POSTAGE.

PER ANNUM, IN ADVANCE. $5 00

SINGLE COPIES. 10 CENTS.

Subscriptions may begin at any time. The safest mode of remittance is by bank check or postal money order, drawn to the order of the undersigned. When neither is accessible, remittances may be made at the risk of the publishers by forwarding in REGISTERED letters.

CHICAGO, ILLINOIS.

SATURDAY, NOVEMBER 28, 1885.

THE NINTH INTERNATIONAL MEDICAL CONGRESS—WHY FURTHER OPPOSITION SHOULD CEASE.

All who have given due attention to the progress of the work of effecting the Preliminary Organization of the Ninth International Medical Congress will remember that the sudden and apparently concerted withdrawal of prominent members of the profession, in Philadelphia and two or three other cities, from further participation in such organization immediately after the first meeting of the Committee of Arrangements, which was held in Chicago in June last, was in its terms *conditional*. Each notice of withdrawal ended in substantially the same language, namely "*as now proposed to be organized*."

This language clearly implied two ideas. First, that there was something either in the Rules that had just been adopted by the Committee, or in the *personnel* of the organization, or in both, that those withdrawing could not sanction. And second, that if such objectionable features were removed, those withdrawing might renew their cooperation. The only Rule ever mentioned as objectionable was that relative to the conditions of membership in the Congress, which had been so changed by the Committee as to limit the American Membership to delegates from the American Medical Association and from such State and Local Medical Societies as were in affiliation therewith, thus cutting off delegates from all the National Organizations of Specialists. As soon as this proposed restriction of American Membership became known, it was declared unnecessary and injudicious by all parties. This, and the discovery that no provision had been made for an Executive Committee of the Congress to take charge of its interests after the Preliminary Organization had been completed, caused the Committee to defer any official announcement of the Rules or Organization until more mature consideration and another meeting had been held. But from the persistence with which the opposition denounced the Committee and created the erroneous impression in Europe as well as among their own friends at home, that the officers of the Committee were to be officers of the Congress, it was clearly apparent that much the larger part of the opposition was founded on purely personal considerations. We say the *erroneous* impression, because it must be kept in mind that the Committee as enlarged by the American Medical Association in New Orleans, at its first meeting in Chicago organized purely as a Committee of the Association to provide such necessary Preliminary Organization for the Congress as would enable it to assume full and independent charge of its own affairs. So far from claiming for itself or its Chairman and Secretary any official position in the Congress, the Committee adopted a rule at the commencement of its work, that it should appoint none of its own members to an official position in the Preliminary Organization of the Congress.

When the prejudices and passions of the hour have passed by, history will show that this much abused Committee of Arrangements was composed very largely of intelligent, conservative and truly representative men of the profession in their respective States, men who comprehended the nature of the duties assigned to them, and who were earnestly desirous of maintaining the harmony and best interests of the profession of our country and of the International Congress. Consequently, after giving due heed to suggestions from all parties, the Committee again assembled on September 3, in New York, and with much unanimity so altered the previously restrictive rule in regard to the American Membership as to do away with all delegations from other medical organizations, and to open the doors of the Congress to members of the regular medical profession in this and all other countries, with no other condition than that they enter their names on the register and take out tickets of admission. In other words, the conditions of membership were made essentially the same as in the preceding Congresses in London and Copenhagen. By the adoption of Rule 10 the Committee also made provision for an Executive Committee, not of its own members but of the general officers and presidents of Sections of the Congress itself, with power to take full charge of all the interests and management of the Congress as an independent and self-sustaining organization, from the time of their appointment until the work of the Congress should be completed by the publication of its transactions Having thus revised and adopted such rules as obviated all the objections hitherto made against the previously proposed conditions of membership, and provided for an independent organization of the Congress to be controlled and managed by an Executive Committee composed of its own chief officers, the Committee of Arrangements then selected the general officers and presidents of Sections, so far as was necessary to bring into existence the Executive Committee provided for in Rule 10, and by the adoption of a special resolution, transferred all the unfinished details of organization to the said Executive Committee, with full power to fill all vacancies, add a limited number to its own body, and to take full charge of the affairs of the Congress The power to add to the number of the Executive Committee was given for the purpose of enabling a number of the most prominent of those who had withdrawn their support under proposed regulations essentially different, to accept places on the Executive Committee and again participate actively in all the interests and management of the Congress

It is apparent, therefore, that the Committee of Arrangements, at their September meeting, deliberately and properly so shaped their action as not only to remove all the objections that had been urged against the rules as previously proposed, but also to open the way for all interests in the profession to again unite in sustaining the Congress as a true, independent, international organization, under the exclusive control of an Executive Committee composed chiefly of its own responsible officers It only remains, therefore, for the present Executive Committee of the Congress to fill the vacant places in its own body by offering unreservedly several appointments to as many of the most prominent of those who had previously withdrawn as their places will admit, before filling any other important vacancies If they accept, an end will be put to the dissentions regarding the Congress, without compromising the principles of any party Can there be a reasonable objection to such a course of action!

DR INGLIS'S ADDRESS

It is seldom that one has the opportunity of reading an address before a medical body which contains so much and so varied suggestion as the Address of DR DAVID INGLIS before the Detroit Medical and Library Association, published in this number of the JOURNAL While it is in no sense a valuable contribution to our knowledge of any *one* department of medicine, and was not intended to be, it would be well, indeed, if each member of every medical society in this country could read and study it thoroughly, thoughtfully and carefully, for there are some valuable lessons to be learned from it

The first lesson to be learned from it is—what has been and is often thought to be an impossibility—that a number of medical men can work together in peace and harmony, without wasting the time of the society and lowering themselves in the estimation of their fellows by quarrels and bickerings, usually of an entirely private nature This opinion seems to be so thoroughly grounded in the minds of some members of certain societies that they do not seem to think any meeting of the society complete, or that the time for adjournment has come, until a certain number of epithets have been passed, and at least one committee has been appointed to investigate some one or more members of the society In a few cases the real nature of a medical society seems to be forgotten, and the impression prevails that the reading and discussion of papers is an altogether secondary matter, the time for which is *after* the weekly, bi-weekly or monthly disagreement has been referred to a committee The case of the Detroit Society may or may not be unique, but it is certainly interesting to know that ninety-five physicians *can* lay aside personal animosities in their society, and work together for a whole year without one instance of animosity or contention "The great need of our profession is unity no other profession allows personal animosity to so weaken its power as does our own"

Dr Inglis refers to the large number of pathological specimens that have been presented at the meeting of his society during the past year, in itself a sign of a *working* society It indicates, as he says, an increasing thoroughness of investigation on the part of the members There can be no question that any paper that can be illustrated by specimens is far better if the specimens are presented There is an amount of wholesome proof in a specimen that can never be obtained from a mere statement And it is a matter that must ever be regretted that the laity look upon autopsies with such horror Should the time ever come when they can be educated to the fact that such things are for the good of humanity, the millenium of medicine will not be far distant, for they will then be also educated to many other equally important facts

From the Address we learn that set debates have done much to maintain the interest and promote vigorous life in the Detroit Society This plan might be adopted with obvious advantage by other societies It will at least insure some carefully prepared remarks on one subject, as opposed to the frequent exhibition of careless remarks on many subjects (It is not too much to say that medical society meetings are sometimes hopelessly tiresome on account of the disconnected and frequently valueless remarks of unprepared speakers But this fact has already been pointed out in a recent editorial article in the JOURNAL, and need not be dwelt on further)

The subject proper of the Address is embodied in the question, What is to be the future of therapeutics? In regard to our materia medica, Dr Inglis thinks that the first thing to be done is to establish the place of action of the various drugs "Of many physicians using the same general group of drugs one will achieve better results than the rest, simply by a more accurate judgment of the adaptation of the remedy " This, we think, sufficiently accounts for the amount of what we may call "therapeutic skepticism" among many physicians, of which our author speaks It is scarcely possible to conceive of a physician who can judge of the adaptability of a drug, and who only uses it when it is indicated, who is skeptical as to its value It is undoubtedly the fact that we should "more thoroughly work out the detailed symptoms of each disease " The man who does this, who discards the idea of "a pneumonia," or "a typhoid fever," and treats indications must be far from skepticism And we cannot altogether agree with our author that "we have fallen lamentably behind in the study of symptomatology " It must certainly be admitted that much has been added to symptomatology within the past few years, the case of cerebral tumor so acutely diagnosticated by Hughes Bennett, and operated on by Godlee, is an apt illustration of this fact At the same time, we must agree that the "only basis for a scientific therapeusis is to be found in an exact knowledge of two kinds of facts *first*, what is the precise effect of a drug upon the functions of healthy organs, and *secondly*, what is the effect upon organs whose functions are already disordered?" Here we at once come to the field of Pharmacology, the importance of which was spoken of in this JOURNAL only a short time ago—and it is an importance which can scarcely be overestimated And it is entirely proper to say that the only basis for a scientific therapeusis lies in a greater attention to, Pharmacology, in a closer and a more general study of this branch of medicine

In connection with the importance of a more thorough study of pharmacology, in order to establish a basis for a more scientific therapeusis, we may refer to that portion of the Address which speaks of the use of proprietary medicines While it is a fact, and one to be deplored, that physicians use these preparations, a part of the fault at least must be laid at the door of their teaching And while there is much to be said against the practices of many manufacturing pharmacists, there is also much to be said in favor of some Merck, of Darmstadt, is a manufacturing chemist, but we much doubt if a dozen physicians in all Europe and America would go so far as to say that his methods are objectionable, or that it is improper to use drugs known by his name Our strictures should be directed to the abuse, not the use, of manufacturing pharmacy And it is entirely probable that many of the abuses even of "patent medicines" could be stopped if the State would take a little more interest in the health and lives of its citizens But as one swallow does not make a summer, so one physician who prescribes proprietary or patent medicines does not represent the profession As regards the unfairness of such prescribing to our own pharmacists, it may be said that if they would refuse to sell these goods they would not be sold to the extent that they are now The small pharmacies are much more responsible for this state of things than are any members of the profession, both by selling these articles and by counter-prescribing

Finally, much of the uncertain and unscientific therapeusis of the present day should be laid, we think, at the door of those who are so badly affected with the *cacoethes scribendi* as to publish books of formulæ, in which one formula is given for the treatment of "pneumonia," another for "bronchitis," and so on to the end of the nosological list, as though a disease was always a determinate and definite entity, varying no more than a mathematical problem These books seem to be written in order that the purchaser may use them as he would a dictionary They are dangerous in the hands of a person who needs them, and those who do not need them never buy them

TEMPERATURE OF THE ABDOMINAL WALL IN ENTERITIS OF CHILDREN

PROFESSOR MONCORVO, of Rio de Janeiro, has recently communicated a very interesting note on this subject to the Academy of Medicine of Paris It is now about three years since he commenced a series of investigations on this subject, and some of his conclusions were announced two years ago by one of his pupils He had already applied Peter's method of thermometry of the chest to children, and his satisfactory results induced him to ascertain its value in affections of the abdominal organs—chiefly acute and chronic enteritis Dr Moncorvo has exceptional facilities for work of this kind in his capacity as Professor of Diseases of Children in the Rio de Janeiro Policlinic He makes no statement as to the number of cases examined, but his reputation as an acute clinician precludes any doubt as to the thoroughness or accuracy of his observations

As is the case with most diseases in the Brazilian Capital, it seems, acute and chronic enteritis of children are very frequently complicated by malaria, or are of malarial origin, a fact which North American physicians can readily understand Not only is this the case, but it is not at all infrequent that the malarial intoxication in children seems to be localized in the intestinal canal, and that the diarrhœa and intestinal symptoms are so predominant as to mask whatever other symptoms may be present, and may persist long after all other signs of malarial intoxication have disappeared This being the case, there must necessarily be more or less difficulty in making correct thermometrical observations, since any change in the temperature due to the malarial poison itself must be excluded in taking account of changes due simply to the intestinal affection

Having found by means of a Casella thermometer (in which the reservoir of mercury is encased in wood, so as to be beyond the reach of external causes of error), that the normal temperature of the abdominal wall of young children varies between 95° and 98 8° Fah, according to the age of the subject and time of observation, he classified the patients into two groups in the first were placed those cases of enteritis in which there was an elevation of rectal or axillary temperature—febrile cases, in the second were placed the non-febrile cases, in which there was only a greater or less degree of diarrhœa In the first class of cases the temperature was always very high, the average being 100 2° And as the increased local heat is directly dependent upon the elevation of the central temperature, it is easy to draw conclusions as to the influence of the intestinal affection In the second class of cases abdominal thermometry may also be of great value Moncorvo states that in the greater number of these cases he has been able to note the progress of the intestinal affection by close attention to the thermometric curve His observations show that the surface temperature of the abdominal wall rises a little before the diarrhœa sets in On the other hand, he has found that the thermometer still recorded a temperature of 97 4° when the diarrhœa was said to have disappeared, but investigation would show that the stools were not yet normal The intestinal mucous membrane has not yet regained its physiological condition, and the fact is shown by the thermometer

By this means, therefore, we are in a condition to give a much more certain prognosis, and to know the date of termination of the enteritis During the entire course of the disease the local temperature is more or less elevated according to the severity of the case, the temperature ordinarily varies between 97 4° and 98 8° That the local temperature decreases precisely in accord with the declination of the intestinal affection is a further proof of the value of local thermometry in these cases As the alvine evacuations decrease day by day under the influence of proper treatment, the local temperature falls in a direct and constant ratio

SOCIETY PROCEEDINGS

PHILADELPHIA PATHOLOGICAL SOCIETY

Stated Meeting, October 22, 1885

THE PRESIDENT, J C WILSON, M D, IN THE CHAIR

DR J COLLINS WARREN, of Boston, read a paper on

A COMPARISON OF THE CHANGES IN ARTERIES AFTER LIGATURE, AND IN THE DUCTUS ARTERIOSUS AND UMBILICAL ARTERIES AFTER BIRTH

After the ligature of an artery in continuity, the earliest changes noted are the formation of the thrombi within the vessel and the development of a mass of inflammatory tissue or callus around the point of ligature externally No perceptible cell action can be observed in the inner wall with low powers during the first week, although under favorable circumstances a proliferation to a limited extent of the endothelial cells near the point of ligature can be seen with high powers, and occasionally a few wandering cells may be found to have penetrated the walls of the vessel at the same point In the second week, the bundle of fibres of the adventitia, which were surrounded and held by the knot, have been absorbed, and the two ends of the vessel retract slightly from one another, leaving the ligature imbedded in and partly disintegrated by the granulation cells The walls of each portion appear to form a complete cul de sac, and it looks at this time as if the healing process were complete, but it can hardly be said to have more than begun, as the vessel has not yet passed through what may be considered as the first stage of healing

The beginning of the second stage is marked by an unfolding of the ends of the vessel, the walls separating somewhat after the manner of opening of a bud, which permits the entrance of a considerable quantity of the granulation tissue A disintegration of the thrombus follows, and we have now a fully developed external and internal callus, a small fragment of clot still protecting the latter from the current The ligature may be totally disintegrated and absorbed, or it may have become encysted, or finally it may have created a small abscess about itself which has discharged the fragments of thread through a sinus opening externally The second stage is completed when the internal growth has reached the neighborhood of a branch After this we have an absorption of the callus, which, as in fracture, is only a provisional structure, and eventually the two ends of the vessel are found held together by a slender cord of varying length The walls of the vessel are slightly separated at each end by a a cicatrix consisting of connective tissue externally, inside of which is another layer consisting largely of unstriped muscular fibre, the surface being covered within by a new endothelium The cicatrix is always pierced by a vessel which terminates in a number of capillaries ramifying in the cord We have here a scar made up of three layers resembling closely the three coats of the vessel In the large vessels of amputation stumps we have a somewhat different series of changes Soon after the ligation, the end of the vessel may be seen imbedded in granulation tissue, and containing a thrombus of varying length By the second week there is a marked change in the intima extruding for some distance above the point of ligation, probably to the first large branch or to the origin of the vessel

Examined several months later, when the healing process has been completed, the vessel is found to be preserved in the form of a cord running from the first large sized branch to the cicatrix of the stump, on laying open this cord the walls of the vessel are found preserved, the interior being filled with new tissue, leaving spaces occupied by one or more vessels There has been a process resembling that known as obliterating endocarditis, by which the calibre of the blood channel has been narrowed to an extent to adapt it to the diminished supply In this obliterating tissue we find comparatively large vessels with new cords consisting of the endothelium, an elastic membrane, and also a new media An erosion preparation would best represent the condition of the arteries of the stump at this time The main artery would, after giving off its largest branches, break into a spray of smaller vessels, no one of which would predominate

A comparison of these two modes of healing with the changes in the arterial system seen after birth shows certain resemblances in the two processes The ductus arteriosus, about the time of birth, differs considerably from the structure of the aorta and pulmonary, artery The media is much thicker than in either of these vessels, it is thrown into irregular folds which are increased at the time of birth, and help to narrow its calibre The distinctions between the different layers of its wall are less marked than in other vessels The lamina elastica is indistinct and in places apparently wanting, the media consists chiefly of longitudinal layers of muscular fibres, a few circular bundles existing in the innermost layer A few weeks after birth, a greater portion of the walls of the ductus undergoes hyaline degeneration, the inner or circular fibres of the media alone remaining, these being reinforced apparently by a growth from the media of the larger vessels At this time there is an active growth of long spindle shaped cells, with staff shaped media, at the edges of the media bordering on the opening into the aorta there is also moderate thickening of the intima Eventually the hyaline tissue becomes absorbed and is replaced by a ligamentous band of fibres, which becomes continuous at either end with the media of the larger vessels At the aortic end, in a longitudinal section, we see the media slightly separated At the point of the cicatrix, and between them and also continuous with them, are the longitudinal fibres of the ligamentum arteriosum In this ligamentous tissue and between the edges of the media are numerous new muscular cells, nearer the surface is a layer of thickened intima, which in the aorta has not only connective tissue in it, but also a deep muscular elastic layer, in the centre of the depression marking the site of the cicatrix a small round vessel is given off, which penetrates into the axis of the ligament, where it either loses itself in the capillary network or becomes continuous with a similar vessel coming from the pulmonary artery We have here conditions closely resembling those which have been described as existing in the cicatrix of a large artery after ligature in continuity, namely the slightly separated ends of the media, between which lie the fibres of the ligament connecting it with the pulmonary artery, a new intima and a new growth of muscular cells, and finally a central arteriole The only point of difference is the preservation of a layer of circular muscular fibres which form an outer wall to the ligamentous band, a much needed support at a point exposed to great tension Further protection is afforded by the oblique insertion of the ductus into the aorta, diminishing the pressure upon this particular point At birth the umbilical artery, or that usually called the hypogastric artery, the portion within the abdomen, at its origin from the internal iliac is a vessel of considerable size, being, in fact, a continuation of that artery At its termination in the umbilical wound it has greatly contracted, and is filled with clot for a distance of about one inch

The outlines of the various walls are not as distinct as in other vessels, and the elastic lamina for the most part wanting No special change is seen in the elements of the walls of the vessels, except a slight accumulation of endothelial cells near the apex of the thrombus A few weeks later, there is a distinct growth on the inner surface of the wall up to its point of origin, the terminal portion having undergone a hyaline degeneration and obliteration for a short distance The vessel has greatly contracted throughout its entire length, and its calibre is further diminished by the growth in its interior Cross sections taken from the artery in adult life show the media as a wall thick out of all proportion to the size of the vessel, and consisting not only of its original wall, containing longitudinal muscular cells interspersed with elastic tissue, but also an inner circular row of cells which is provided with a well formed elastic lamina. It seems probable that the greater portion of the hypogastric artery has been preserved, the ligamentous band which extends to the umbilicus consisting of the obliterated extremity of that vessel much elongated during the process of growth. The series of changes which occur in the hypogastric artery after birth is closely analogous to that seen in the main trunk of an amputation stump—a slight portion of each vessel is destroyed, both retract and are attached to the terminal cicatrix by a band of fibrous tissue, both remain as pervious vessels with thickened walls and narrowed calibre. In both the process is not unlike that seen in the so called obliterating or compensatory arteritis. Arteritis hardly seems a term applicable to the changes taking place in normal arteries after birth, nor can the alterations which have been developed through the whole length of a large vessel extending a considerable distance from the seat of inflammation, be strictly regarded as of an inflammatory nature. May not the obliterating growths found to exist simultaneously in terminal arteries in widely removed portions of the body of the same individual also be regarded not as of inflammatory nature, but rather as a secondary and formative process, closely connected with disturbances in the mechanism of nutrition, designed to adapt the vessels to a diminished blood supply?

Dr. S. W. Gross said that, in view of the fact that Dr. Warren's teaching seemed so distinctly opposed to that of other observers, he would like to have some points cleared up. He would, therefore, ask if Dr. Warren held, 1st, that instead of the external coat where it is included in the ligature, sloughing and coming away with the ligature, the pressure of the ligature sets up an irritation which causes the adventitia to return to its embryonic state, with a reconversion, after the ligature has cut through this, to connective tissue; and, 2d, whether the repair of arteries was brought about by the ingrowth of the cicatricial tissue, which he likened to provisional callus, together with some proliferation of the muscular cells of the media?

Dr. Randall said that, as the result of careful study of the subject, he had always found the clot present at first, and that it was honeycombed even in the first few days by the contraction of its fibrin, through the spaces thus formed the blood seemed to be circulating. Cells, either original white cells or of endothelial origin, occupied the walls of these cavernous spaces and seemed to sheathe them. The red cells early melted down into a homogeneous mass, furnishing the framework upon which the reparative tissue was built. The "plastic clot" of some observers he had not seen, the new cells being distributed throughout the old clot as well as upon the vessel walls and not specially collected in the immediate neighborhood of the ligature. The obliteration of the vessel was accomplished by the growth and contraction of the trabeculæ of new tissue built upon the remains of the original blood clot. Even close to the ligature he had not found the vessel walls greatly altered merely showing a great increase in the nuclei and in the number and size of the vasa vasorum, the lamina elastica being distinct, and, as a rule, intact. Toward the end of the first month the new tissue was largely spindle cells, but careful staining had given no suggestion of muscular tissue. But, not having carried his study beyond the first month, he had no data upon this subject, since the development of muscular tissue is claimed to occur only at a later stage.

Dr. H. F. Formad was inclined to favor the views of Dr. Randall. The observation of Dr. Warren that the new-formed connective tissue played the most important part was to him entirely novel. He thought probably the pressure upon the artery from without, with consequent diminution in its lumen, might bring about a condition more analagous to the growth of fœtal life than to inflammation.

Dr. Mears remarked that we are liable to be confused in considering this subject by the presence of the blood in the vessel. So far as the process of healing after ligature is concerned, we may consider only the structures which enter into the formation of the vessel wall, which is complex in character, and composed of connective, plastic and endothelial tissues. Dr. Warren has given us a very clear demonstration of cicatrization as it occurs in these structures after application of the ligature.

Dr. Tyson said the most novel feature to him in Dr. Warren's observations was the part played by the muscular tissue. This apparent increase in the muscular tissue he was inclined to believe was really only a proliferation of intermuscular connective tissue. He was becoming more and more convinced that there was only one kind of inflammation—the interstitial. He feared that he might himself mistake a proliferating connective tissue with spindle cells for muscular tissue. It is true that new-formed capillaries and arterioles have muscular walls, but the development of these seemed to him to be a slower process. He had expected to find a process of repair in the ductus arteriosus different from that in an ordinary artery. This process he had expected would be a true endarteritis, for it seems that the conditions of closure here are rather different from those in the ligaturing of an ordinary artery and in the umbilical artery, where we have also ligation practiced.

Dr. Warren, in closing, said in cases where there is much breaking down and little repair, there might be a sloughing of the external coat, yet, in his experiments, this part of the arterial wall did not slough, but was simply absorbed by the granulation tissue, as is the ligature itself in some cases. In the normal condition even, the elastic lamina is not a perfectly continuous plate, he did not refer to these breaks, however, but to numbers of little ruptures incident to the pulling out of the wound of an artery in the act of ligature—however, this need not necessarily occur. He had not attempted to identify anything like muscular tissue early, this could not be recognized till we had a permanent cicatrix formed. He had carefully eliminated all sources of error, and it seemed to him that in almost all cases there was a considerable number of these muscular cells. The layer was not always as well marked as in his diagrams, especially was this true of human cases, but these had all been in alcohol for some years, of the fresh specimens he had selected only those in which he had considered the process complete In a specimen which he had here to night, through an opening in the lamina elastica cells could be traced from the muscular layer, those in the inside resembling exactly those outside These facts, together with the fact that we have normally a few muscular cells inside of the lamina elastica, lead him to believe in the proliferation of the muscular tissue The disintegration of the blood clot is accomplished by granulations growing inward from the callus, there being two sets of blood vessels, one in the granulations, the other, (blood spaces, rather) in the clot itself, these unite about the end of the first or second month

---

Stated Meeting, November 12, 1885

THE PRESIDENT, JAMES C WILSON, M D, IN THE CHAIR

DR FUSSELL presented

SPECIMENS FROM A CASE OF MASTOID DISEASE

The patient was a male, æt 25 years Never had scarlet fever Since vaccination at the age of 5 years, has had occasional attacks of suppuration of the middle ear General health was good Was first seen by Dr Fussell July 14, for several weeks he had had earache, with one slight chill When seen hearing was very poor, membrana tympani opaque, swelling and redness over left mastoid process and temperature elevated His general condition grew worse, and an incision was made over the mastoid process, but it failed to find pus On extending this incision a few days afterward, pus flowed freely, and he was much relieved He afterward grew worse, fell into a typhoid condition and died July 24 Before death, blood oozed freely from the cutaneous surface At the autopsy, the mastoid cells were found filled with pus, in the inner half of the process was a large irregular cavity filled with a pultaceous mass of necrosed bone, this communicated with the middle ear The walls of the lateral sinus were thickened, easily detached from the bone, and the seat of a purulent inflammation The sinus contained no thrombus The meninges over this spot were discolored, though not inflamed, but there was a patch of inflammation over the anterior edge of the left lobe of the cerebellum Brain substance was normal Remaining organs were not remarkable, except the right lung, which contained in its apex two small abscesses From the condition of the sinus, the reporter thought there had been an actual admixture of pus with the blood

DR ~~JOHN H~~ PACKARD presented

[illegible]

AN ANOMALOUS LUNG

It was taken from the body of a negro who died of Bright's disease From the inferior surface of the lower lobe of the right lung springs a tongue shaped process of pigmented, crepitant lung tissue two and one half inches long and two inches wide at its base, resting upon the diaphragm, its upper surface being in apposition with the under surface of the lower lobe Dr Packard had recently seen in the body of another negro a similar anomaly, except that the process was smaller and situated more anteriorly

DR J H MUSSER presented a

CYSTIC KIDNEY

It was the right kidney, and was taken from the body of a man, æt 72 years, who died of apoplexy The kidney was cirrhotic and contained two cysts, the larger occupying the upper one fourth of the organ Its walls were firm, and it contained clear fluid in which floated cheesy masses, which the reporter thought were degenerated pus When first seen, the patient was passing small quantities of bloody, highly albuminous urine, and complained of pain in the right renal region These symptoms were apparently due to an acute process grafted upon the chronic lesion The blood and most of the albumen disappeared, but the pain persisted Was this pain due to the cyst?

DR MUSSER presented also a

CARCINOMA MAMMÆ

removed from the body of a woman, æt 75 years The breast had been injured eight years ago, and three years afterwards the tumor noticed There was never any pain in the tumor The lymphatic glands of the axilla were involved In addition there was a large lipoma of the back of the arm She had frequent attacks of severe pain in the tibia and left parietal bone, apparently due to periostitis, and not to any secondary growth There was no syphilitic history

DR MUSSER also presented

SPECIMENS FROM A CASE OF DIABETES MELLITUS

The patient was a female, æt 43 years Had a vesico-vaginal fistula for fourteen years Diabetes had persisted, without apparent cause, two months Patient was unusually fat, and had lost no weight She died of coma Temperature in the abdominal cavity three hours after death was 107 8° F Liver large and fatty, gall bladder contained thirty stones Kidneys fatty Pancreas normal Blood had a most marked lactescent appearance, and after standing twelve hours globules of fat collected on its surface Lacteals in the mesentery engorged with chyle Microscopic examination of lungs showed no fat emboli In the urinary bladder was a large phosphatic calculus Dr Osler thought the peculiar condition of the blood was what we should find normally in a person dying during digestion, and called attention to the fact that very frequently in diabetics there is the engorgement of the lacteals

DR MUSSER also presented a

FŒTUS PAPYRACEUS

The mother was delivered in the morning of a mature living child, and in the evening of this fœtus It is apparently of the fifth month of pregnancy, and with the exception of shriveling and paling of the skin, is quite normal The cord is thin and soft, its length unknown The placenta is thin, flat, compact, and whitish yellow, apparently having undergone complete fatty degeneration

Dr John B Roberts presented a

SMALL TUMOR, THE SIZE OF A HICKORY NUT, REMOVED FROM THE BACK OF THE WRIST OF A YOUNG MAN

It had the clinical appearance of an ordinary ganglion, but attempted evacuation showed it to be solid It was then enucleated and found to have been developed within the theca of the tendon going to the middle finger, and probably between its fibres The great rarity of solid tumors in this locality was mentioned

Dr Wm Osler asked if the patient had a rheumatic history, although this specimen was rather large for a subcutaneous nodule occurring in rheumatism

Dr Roberts knew nothing of the history

Dr C B Nancrede presented *Fluid from an Encysted Hydrocele*, which fluid contained large numbers of dead spermatozoids

Dr W E Hughes presented a

PRIMARY CARCINOMA OF THE LIVER

Female, æt 58 years A daughter died of cancer of the uterus She had been in good health till 18 months ago, when flesh and strength began to fail With this there were occasional attacks, lasting about a week, of headache and sick stomach, followed by diarrhœa There was pretty constant lancinating pain in the hepatic region Five months ago she had an attack of jaundice (her only attack), lasting two weeks, and at this time a humor was detected in the liver At the autopsy the liver was found much enlarged, and scattered through its substance were firm cancerous nodules varying in size from an orange to a pin head In addition to these there were several cysts, one in the left lobe two inches in diameter, filled with clear fluid The liver substance between the cancerous nodules was normal The gall bladder was full of healthy bile and the ducts patulous There were no enlarged glands in the fissure of the liver, but the retro peritoneal and mediastinal glands were increased somewhat in size, and the seats of secondary deposits, with these exceptions these was no growth outside the liver The intestines were crowded into the left side of the abdomen by the enlarged liver The stomach was very small, only one inch in diameter at its fundus There was an intussusception, three inches in length, at the ileo cæcal valve, which, on being reduced, which was effected with some difficulty, showed the opposed surfaces of peritoneum covered with lymph

Dr H F Formad presented specimens and read a paper on

AN ANALYSIS OF 250 AUTOPSIES ON DRUNKARDS, ILLUSTRATING THE MOST PROMINENT ANATOMICAL LESIONS OF CHRONIC ALCOHOLISM

He considered the most conspicuous lesions to be cyanotic induration of the kidneys, fatty infiltration of the liver, and mammillated stomach His cases had been those in which there had been a history of a long-continued series of debauches, the subjects often dying in one of these debauches, and did not include moderate drinkers or those who perished after imbibition of an enormous quantity of alcohol without any previous chronic causes He thought that the exposure, irregularities of diet, etc, incident to a state of drunkenness, had much, probably more than the alcohol itself, to do with the production of the lesions, but it was not at all possible to separate one from the other He gave a long list of lesions considered by various authors to be results of chronic alcoholism, among which the cirrhotic liver, with contraction, held a prominent place He had had himself at one time considered cirrhosis a very frequent, if not almost necessary, concomitant of long-continued excessive use of alcohol, and had even testified in court that a certain person was not likely to have been a hard drinker because at the autopsy no cirrhosis of the liver was found He had thought, too, that the connection between the two was so close that it was impossible to have a case of cirrhosis without a previous history of alcoholism, as is held by various authors, Therefore, it was surprising to him to meet in his 250 autopsies with only six cases of cirrhosis of the liver with contraction, In 220 cases the liver was considerably or even very much enlarged, the enlargement in most cases proving to be due to a fatty infiltration Cyanotic induration of the kidney, and chronic gastritis with mammillation of the stomach, were found in nearly every case This cyanotic induration is peculiar, and differs from the cyanotic induration due to heart disease At a future time he will give a detailed account of the above lesions, and a more extensive analysis of the cases

Dr James Tyson could not speak from a systematic observation of a large number of autopsies in the cases of confirmed drinkers, but he remembered distinctly being surprised, in several cases, by the absence of cirrhosis where he confidently expected to find it

Dr Wilson said that Anstie, in the article on alcoholism in "Reynold's System of Medicine," had called attention to the comparative infrequency of contracted liver in confirmed drinkers This observer, in an extensive out patient practice in London, had seen large numbers of cases of alcoholism, but very few among them presented the physical signs of cirrhotic (contracted) liver The experience of the staff at Blockley Hospital confirms this view There many of the patients are soaked with alcohol, but even among those whose death is directly or indirectly due to alcoholic excess, fatty liver is much more common than contracted liver

Dr Osler thought the experience of pathologists and morbid anatomists with histories of patients not of the most satisfactory character, he often having had cases to dissect where he knew very little of the history Before saying these cases were chronic alcoholics Dr Formad should present more specific statements about them His own experience with livers, in a large number of autopsies on cases of chronic alcoholism, had led him to divide them into four classes 1 Those in which the condition of the liver is pretty satisfactory, some of these cases may take alcohol for many years and yet the liver pass muster 2 Fatty cirrhotic livers, the cirrhosis may not, perhaps, be distinct to the naked eye but plainly shown by the microscope, this is the largest class 3 Hobnail livers, these he would say were much more common than in Dr Formad's series 4 Hypertrophic cirrhotic livers The difference between his observations and those of Dr Formad might possibly be accounted for by a difference in the form of alcoholic beverage taken He had not observed the special form of kidney described by Dr Formad In reply to a question, he said in order of frequency he would place them fatty cirrhotic, hobnail, hypertrophic cirrhotic, apparently normal

Dr S Solis Cohen said that there were certain theoretical considerations which suggested themselves in this connection The text books teach that the lesions of alcohol are of two kinds, sclerosis and steatosis It is known that in some organs the fibrous change precedes the fatty one The latter is the higher grade of degeneration The subjects of Dr Formad's autopsies were confirmed whisky soakers, in whom one would expect to find more intensity of degeneration than in those whose use of alcohol, though persistent and excessive, was not so outrageous Another point which had not been alluded to was the fact that some lesions might result from a local action of the poison upon the tissues, while others might be due to its systemic action No study of the subject could be complete in which these points were overlooked

Dr B A Randall suggested that the point touched upon by Dr Osler—the character of alcoholic beverage—might be very important In Vienna, among beer drinkers, he had found the fatty liver much more common than the cirrhotic, while in England, where much gin is drunk, and he should suppose in Scandinavian countries, where they drink altogether strong spirits, the cirrhotic liver is doubtless comparatively frequent

Dr Musser had recently had to go over the records of the Pathological Society, especially in liver diseases, and had found the total experience of different observers the same as Dr Formad's, and also in those cases cirrhosis was caused not so much by heavy drinking as persistent drinking of spirits on an empty stomach

Dr Formad presented the

SAC OF AN EXTRA UTERINE PREGNANCY

The woman from whom this was removed had not suspected that she was pregnant She was in perfect health until twelve hours before death, when she was suddenly seized with excruciating pain in the left groin, rapidly followed by collapse On opening the abdomen it was found to contain at least a gallon of partly clotted blood About the middle of the left fallopian tube was the sac with a rent in its posterior wall This sac was one inch in diameter and contained clotted blood and placental tissue The uterus was twice its normal size The fœtus was not found

Dr Formad also presented

AN ANEURISM OF THE ASCENDING AORTA RUPTURING INTO THE PERICARDIUM

The patient was a laboring man and had considered himself in perfect health He died very suddenly The aneurism, half an inch in diameter, was situated just above the posterior aortic leaflet and had broken through the wall of the aorta at the point where it touches the descending cava The cavity of the pericardium was fully distended with clotted blood

---

OBSTETRICAL SOCIETY OF PHILADELPHIA

Stated Meeting, Thursday, November 5th, 1885

The President, B F Baer, M D, in the Chair

Dr John M Keating, M D, read a paper on

LYMPHATIC LEUKÆMIA IN CHILDHOOD

The short paper which, by invitation, I propose to read to you this evening will, I am sure, prove of interest on account of its clinical rarity and the infrequency with which we meet the disease in current literature To make the subject more interesting and more lucid, at the risk of recalling to your memory matters already familiar, I will premise with a few remarks on the blood in health in children and briefly with its diseases

There is a uniformity of composition of healthy blood which is curious This is brought about by that equilibrium which is so striking in textures regulated by the production and waste The blood corpuscles which we are called upon to study are 1 The red, of which there are floating in the plasma about 5,000,000 to the cubic millimeter These are about 1 3200 of an inch in diameter 2 The white, of a diameter of 1 2500 of an inch, having the proportion of *1 to every 300 or 500 red* 3 The neucleated red found in the fœtus and infant, and disappearing about the third or fourth year of life These may contain one or more nuclei in some instances protruding from the cell They measure from 1-1400 to 1-2000 of an inch 4 The *hemato blasts* of Hayem—"Small discoid, colorless, corpuscula, normal constituents of healthy blood—in drawn blood they aggregate in clumps known as Schultze's granule masses" As to the origin of the red corpuscles I will quote "They are developed from colorless corpuscles, the lymph cells or leucocytes The nucleated corpuscles of the embryo also aid in the development These nucleated cells disappear early in childhood, and are therefore only in the red marrow" It is Osler's opinion that "they apparently originate from colorless marrow-cells which gradually become more homogenous and hemoglobin develops in the protoplasm, the nucleus degenerates and disappears, when the cell has the appearance of an ordinary red disc" Possibly these nucleated cells may give birth to red cells by the process of budding The relations of the cytogenetic organs to blood formation has always been somewhat debatable ground, the present state of our knowledge may be formulated about as follows "The spleen certainly takes part in the development of colorless corpuscles, but its participation in red blood formation is more doubtful, though the opinion prevails widely that the spleen is one of the important organs in the formation of red corpuscles, the evidence for this belief is of an exceedingly scanty nature

"The lymphatic glands and adenoid tissues in other regions are the seat of constant production of colorless corpuscles, but of their relation to the red corpuscles there is the same lack of information as in the spleen "

Neumann and Bizzozero pointed out the fact that the red marrow appears to be the seat of blood formation In the adult it is the only region in which embryonic or nucleated red cells are found In the young the marrow fills the long bones It is Osler's opinion, and I have quoted from his recent admirable articles on this subject, that the evidences of the development of red corpuscles in the marrow rests upon the constant presence of nucleated cells infiltrated with hemoglobin, and of their fusion In excessive hæmorrhage, natural or induced, it appears to undergo active proliferation, and it is an interesting fact to notice the marvelous rapidity with which the red corpuscles are reproduced after a hæmorrhage The amount of hæmaglobin in healthy blood, according to Preyer, is 13 45 grammes to 100 This relation is important for us to have in mind, as it proves an index to treatment The color test being used, I feel certain that before long it will be a matter of more than ordinary interest to the general practitioner when the means of applying the color test shall be generally adapted, as has been done already to daily practice In the new-born the blood is said to amount to one-tenth part by weight of the body In the adult, one-twelfth to one fourteenth I may also note that it has been shown by Neumann that the liver in the embryo may be the seat of the formation of corpuscles, though in the adult it is the seat of their destruction

Let us now take up the subject of anæmia in children Were I to attempt to do justice to this condition, it would take far more time than your patience would allow We will omit that caused by hæmorrhage, by toxic agents by mineral poisons, by miasm, by syphilis, in which we have an increase in the watery elements, and a diminution in the albuminous, and consider that dependent upon disorder of the blood-making organs themselves, and here we meet with a most difficult problem By the blood-making organs we understand the spleen, the lymphatics tissues and the bone marrow, remembering of course that some of their tissues have also to do with blood destruction We, however, definitely know that an increase in the cytogenetic tissues is associated with disturbances in blood formation The organ undergoes a hyperplasia, particularly of its fibrous constituent, and the marrow of bone changes from normal appearance to one like spleen-pulp The blood of all patients suffering from anæmia presents a reduction in the number of red corpuscles This is true, no matter whether the seat of the trouble is located in the spleen, the marrow of bone, or in the general lymph glands, the white cells may or may not be increased, the clinical features of a case of anæmia will be strikingly alike, let the cause be in any one of the blood making organs, all the more important symptoms will be present To quote once more, such common features would be "the progressive anæmia with its group of circulatory symptoms, the irregular febrile reaction, essential fever of anæmia, the absence of marked emaciation, the tendency of serum, the progressive debility, the recurrence of hæmorrhages, gastric and intestinal, gastric and intestinal disturbances, and the resistance to treatment " These affections that have so many symptoms in common are grouped as distinct diseases under the following heading, viz leukæmia, Hodgkin's diseases (anæmia lymphatica, splenic anæmia, and idiopathic anæmia)

Leukæmia signifies a hyperplasia of the blood-making organs with anæmia and an increase in the colorless corpuscles Of this form we have three varieties, the splenic, lymphatic and medullary Leukæmia is present at all ages, the youngest case recorded by Osler being an infant of eight months The chief symptoms are insidious onset, anæmic appearance, bleeding at the nose or other hæmorrhages, frequent diarrhœa or other gastro-intestinal disturbance The spleen is enlarged, gradually increasing in size from the onset, and finally it may interfere with the circulation and cause difficulty of breathing by pressure Late in the disease the liver is also enlarged The lymph glands in most cases are affected and sometimes slightly enlarged The tonsils and follicles of the phanynx are usually enlarged The lymph glands of the intestines and of the peritoneum are always enlarged Fever is present and increases as the case progresses, and is usually of the remittent type But the most important aid to differential diagnosis is the microscopical examination of the blood This I give in detail in the case that forms the basis of this paper which I will now relate I was called in consultation by Dr J W Gadd, of this city, to see the child with him the latter part of last month, and the following notes were given by Dr Gadd

Mamie McC , aged 4½ years, had measles when about 2 years old, and from which she recovered without complication or sequelæ About August, 1884, the tissue surrounding the eye became much inflamed and swollen The swelling increased so much that the eyelid could not be opened for several days After continued poulticing an abscess formed and broke, discharging a quantity of pus and continued to do so for a considerable time, but finally healed up with small scar The child never complained, yet was pale and did not want to play as other children did I believe this was more due to her disposition than to the effect of any disease About midsummer there appeared a rash, all over her body very thick, and resembling the eruption of measles, as it matured it was crowned with small white caps or heads The epideim soon came off in large patches The child had no fever As the eruption faded the mother observed purplish spots, like bruises, making their appearance These were considered by the parents to be bruises due to falls No attention was paid to her condition until September 28th, when I was called in the evening to arrest an epistaxis which had existed most of the day I found the child lying on a sofa, though able to sit up, with blood slowly trickling from the nose, each nostril contained a large clot The child appeared very anæmic, with slight fever, yet did not complain of anything except weakness The mother stated that the appetite had been very poor for some time past The bleeding from the nose was very easily arrested by removing the clots and packing with a strip of lint in each nostril I also gave the following internally

℞	Acid gallic	gr xxx	
	Acid sulph , dil	♏ xl	
	Ext Ergot, fl	♏ xxx	
	Syrupi	℥i	
	Aquæ q s ad	℥ij	M

S 1 teaspoonful in water every hour

Also ordering her as much milk as she cared to take, with the precaution that she should sip it slowly Tuesday morning I saw her and found her in the same condition, except that the epistaxis had been arrested I thought it best not to remove the lint packing It now being daylight, her mother called my attention to the bruise-like spots over her body There were in size from that of a two cent piece to that of a fifty cent piece, and two of them, situated one over each trochanter, were as large as silver dollars, with the exception of these two they were all, I believe, situated over the soft parts, such as over the belly of a muscle, and varying in color according to age, from a bluish black to a greenish yellow She still had some fever, and her heart was more rapid in its action than normal, hence I gave her, in addition to the gallic acid and ergot mixture, the following mixture

℞	Liq potass cit	ʒj	
	Spts æth nit	ʒij	
	Tr aconiti rad	gtt xv	
	Syr limonis	ʒiv	
	Aquæ q s ad	℥ij	M

S 1 teaspoonful every two hours

Wednesday morning I found her feeling somewhat better, though still having slight fever, pulse 124 per minute and moderately weak in character I did not detect any abnormal heart sounds I renewed the lint packing without any further bleeding and with much relief to the patient I then ordered tr digitalis in three drop doses every three hours, and also the following mixture

℞	Quin sulph	gr viij	
	Tr ferri citro chlorid	ʒj	
	Syr tolu	℥j	
	Aquæ	℥vij	M

S 1 teaspoonful every three hours

Thursday I found the patient, to use her own language, well, evidently much better Fever had entirely subsided, the heart's action remained abnormally rapid The cervical glands were slightly enlarged, but no enlargement of the tonsils and apparently no inflammation of the fauces Treatment was continued with the addition of more nourishing food, beef tea, wine-whey, etc The child seemed so much better that I said it might come to my office the next morning instead of my going there Later in the same evening she took a sudden change for the worse, but I was not sent for until Friday morning Now the patient was suffering from high fever, 104° F in the axilla, pulse 134 per minute, compressible The cervical glands much enlarged and very hard, the bowels had not been moved for twenty-four hours, the tonsils were but very slightly swollen, there were no patches on the throat Thinking that possibly she was developing a malignant form of diphtheria, I at once put her on the calomel treatment until the bowels were moved, giving her three grains repeated in two hours, and then two grains, when the bowels were moved freely and the calomel stopped I also gave suppositories of two and a half grains of quinine every two hours, also

℞	Liq ammon acet	℥j	
	Spts æth nit	ʒij	
	Syrupi	ʒiv	
	Aquæ	ʒij	M

S 1 teaspoonful every two hours

I continued the tr digitalis in five drop doses every two hours I also applied hot flax-seed poultices to the enlarged glands, and at noon plenty of beef-tea and milk, but the child did not care for food, and it was difficult to get her to take any nourishment At mid day I noticed for the first time—although I had carefully and frequently listened before—a systolic heart murmur The temperature was but little affected during the night and next morning (Saturday) at 7 30 I found it as high as ever, 104° F in the axilla Fearing that endocarditis had set in, from the continuance of high fever and the heart-murmur, I at once applied a mustard plaster to the pericardium, followed by a poultice, giving internally potassium iodide and ammonium carbonate, continuing the digitalis until noon, when I met Dr J M Keating in consultation

Physical signs showed, in addition to what has been mentioned, an enlargement of the spleen, yet there was no history of malaria Dr Keating did not think that endocarditis had set in, believing the murmur to be rather of a hæmic character, yet as a stimulant to the heart suggested the application of a blister, internally, very small doses of Basham's mixture every three hours, with the free use of alcohol, beef juice in small amount, etc The temperature to be kept down to 102° or lower by means of the wet sheet On examining a specimen of the urine which had just been passed, and the first that I had been able to obtain, I found it to be of sp g 1016, of a light straw color, free from albumin and sugar The child could not retain either medicine or beef juice The nose again commenced to bleed, to prevent which I again plugged the nostrils Soon large clots of coagulated milk were vomited, the result of having been given by half cupfuls at a time, which was entirely contrary to my direction Her stomach soon became settled and she took brandy and crushed ice in small quantities We wrapped her up in a wet, sheet and then poured cold water over her until the temperature came down to 101° in the axilla, which required about thirty five minutes She was then wrapped in a blanket In two hours the temperature was again 104° We gave several of the wet packs during the afternoon and evening, and, notwithstanding we were at the same time giving 2½ grains of quinine every hour by suppository, the same rise in temperature was observed after each During the night she took her medicine regularly, alcohol and water and beef tea were also administered Sunday morning (the day of her death), I found her to all appearance bloodless, pulse rapid and small, respiration shallow and too frequent, temperature rising to 104° after the wet pack, as before. During Saturday night she had removed the packing from the nostrils, which allowed a slight oozing of blood, and this having been swallowed gave rise to vomiting of clotted blood, this continued, after the bleeding from the nose had been again checked, at intervals of ten to fifteen minutes, which gave me the belief that there was a slight hæmorrhage into the stomach, these clots differing somewhat in form and color from those which I ascribed to the epistaxis. The heart became more rapid—138 per minute—and the patient gradually sank. She died at 6.30, P.M., in great agony, giving two or three shrieks, which were quite loud, considering her weakened condition. Dr. Keating remarked that Dr. William Osler had kindly examined for him a slide of blood and reported as follows: Examination about three hours after withdrawal. *Red corpuscles* present, no special alteration in size or shape. *Colorless corpuscles* greatly increased in number, fifty or sixty in each field of the No. 7 Hartnack. They present remarkable variations in size, many are small, not more than one third the size of the larger forms, they resemble the smaller colorless cells which Virchow has noted to be present in cases of lymphatic leukæmia. Many of the cells have feeble amœboid movements. *Neucleated red corpuscles* not observed. *Schultz's granule masses* (often abundant in leukæmia), scanty.

The relation of the increase in number of the colorless corpuscles above noted to the increase in size of the glands and cytogenetic tissue is indeed hard to solve. The increase in size and hyperplasia of the spleen in leukæmia and anæmia are histologically identical. We must remember that the view that colorless corpuscles are changed into red corpuscles is not fully established, hence, also that it is not proven that the excess of colorless corpuscles is due to failure in the change to red ones. In such cases the prognosis when the disease is detected at its incipiency may be favorable under rigid treatment of fresh air, suitable diet, iron, quinine, and arsenic and salt bathing, but in marked cases that have existed for some time with advanced symptoms, the result is fatal.

DR. WM. GOODELL inquired if there was any distinguishing points between purpura hæmorrhagica and lymphatic leukæmia. If there is a deficiency of red blood corpuscles, why do red patches occur so easily?

DR. KEATING remarked that the subject under discussion was dependent upon certain conditions which physiologists are still debating. In leukæmia we have as a diagnostic feature an involvement of the lymphatic system more or less, a hyperplasia of the tonsils, lymphatic glands of the peritoneum and of the intestines, also of the spleen and bone-marrow, all of them being more or less connected with red cell formation, but the principal diagnostic point is the increase in number of the colorless cells as is noted in Dr. Osler's report just presented. The hæmorrhages in these cases are possibly due to a diapedesis or capillary rupture. In what is known as purpura hæmorrhagica, there is an exudation of blood-cells; or the hæmatin from their destruction, into the rete mucosum and the papillary layer of the cutis, of course capillary ruptures may occur with profuse hæmorrhage. The blood cells (red) are usually diseased, they become crenated, or they cease to form rouleaux, and possibly the plasma may be at fault. The microscope alone will reveal the distinguishing features. Purpura may be considered a symptom accompanying a dyscrasia in which the blood itself is involved, not merely the organs of its production.

(*To be concluded.*)

DOMESTIC CORRESPONDENCE

NEW YORK LETTER

(FROM OUR OWN CORRESPONDENT.)

New York State Medical Association—Relation of the State to Medical Education—Is Tubercular Consumption ever Inherited—Discussion on Pneumonia, Is it a Local Disease? Is it due to Micro-Organism? Its Fatality, Remedies for It, Blood-letting, Alcohol, Antipyretics.

The meeting of the New York State Medical Association, which was held November 17, 18, 19 and 20, was in every way a most gratifying success, and an enormous amount of scientific work was accomplished at it. During the four days there were no less than eight day sessions and three night sessions, and there was quite a full attendance at all of them.

The address of the President, Dr. John P. Gray, of Utica, was devoted principally to the "Relation of the State to Medical Education," and in it he took very strong ground against the organization of a State Board of Medical Examiners. To take away from corporate schools of medical learning, which were the property of private individuals, and the students of which paid for their own tuition, he said would indeed be an anomaly in political economy. It would only tend to degrade the schools, and would transfer students, who came to New York from all parts of the country and from foreign countries, to Boston, Philadelphia and other cities. The same opposition to a State Board of Examiners was also expressed in the address on State Medicine, delivered by Dr. Alfred L. Carroll, Secretary of the State Board of Health. From his official intercourse with the physicians of the State it was evident, however, that the medical schools turned out many incompetent men, and a considerable portion of the address was devoted to the need of a preliminary education and a more thoroughly enforced scientific training of candidates for the degree of Doctor of Medicine.

Among the papers read on the first day was one on "Tubercular Consumption; Is it ever Inherited?" by Dr. H. D. Didama, of Syracuse. The principal conclusions of Dr. Didama were that tuberculous disease is not inherited, that if a special tendency to the disease is transmitted, the term *liability* expresses the idea better than *tendency*, and that two conditions are always indispensable for the causation of the disease, viz.: abundance of bacilli and an inviting asylum for their development, whether the susceptibility is inherited or acquired To the discussion of the subject of shock, short papers were contributed by Drs Frank H Hamilton and E S F Arnold

Undoubtedly the most notable portion of the scientific proceedings during the whole session was the general symposium on the subject of pneumonia, which came off in the evening of this day The discussion was opened by Dr Austin Flint, in a brief paper in which he propounded eight questions relative to the nature, pathology, prognosis and treatment of acute lobar pneumonia, and in a clear and judicial manner brought out the most important points bearing upon the various problems connected with the disease In the course of it he mentioned that he had never seen a case of relapse in this affection, and expressed his conviction that there was no tendency whatever to relapse in it, a point which he considered to argue strongly in favor of pneumonia's being a continued fever The occurrence of an attack of it, however, did not diminish the susceptibility to a future recurrence of the affection, a point in which it differed from the ordinary essential fevers A few years since Niemeyer and his school had attempted to show that pneumonia often led directly to pulmonary phthisis, but Louis, more than half a century ago, had satisfactorily demonstrated that it was characterized by no such tendency, and later researches had abundantly confirmed his results

The first question, Is lobar pneumonia a primary local inflammatory disease, or is it an essential fever, the pulmonary affection being secondary thereto and constituting its anatomical characteristic? was discussed by Drs Henry D Didama, of Syracuse, and F W Ross, of Elmira, in excellent papers in which they both took the ground of its being an essential fever, and presented in a concise manner the various arguments in favor of this hypothesis Dr Didama remarked that three views regarding the nature of this disease had widely prevailed at different times The first was that, preceding the *pneumonic* attack, there was a morbid increase of fibrin, with the addition of a certain unknown element, in the blood, the accumulation going on until there was an explosion in the form of a chill, followed by fever, and that the lungs had a special affinity for the blood in this condition The objection to this view was that the preexistence of hyperinosis was merely assumed, and not demonstrated That it was erroneous was shown by the fact that in acute rheumatism hyperinosis constitutes a marked feature, but it does not produce pneumonia The second was the inflammatory view, which regarded the affection as an ordinary phlegmasia, in which there are predisposing and exciting causes, and in which, when the inflammation has run its course, the disease ends But, he contended, the ordinary causes of phlegmasia were not sufficient to excite pneumonia, as was the case in bronchitis, however, it could not be produced experimentally, and it differed from the ordinary inflammations in the marked severity of the chill inaugurating it and the high grade of fever attending the attack, which, in the early stages, at all events, could not be accounted for by the local trouble present

The third view was that it was an essential fever In connection with this he remarked that the belief seemed to be gaining ground that all communicable diseases are of germ origin If, however, pneumonia be a constitutional affection, why are the lungs always implicated, and why, as is most frequently the case, but one lung, and only one lobe of that? In reply to this question, he said that many pathologists considered that each essential fever has its special local manifestation, well marked instances of which could be found in the case of typhoid fever, epidemic cerebro-spinal meningitis, glanders, and other infectious diseases In most of the general affections which had a local predilection, however, a number of organs were likely to be involved in the diseased process This was true also of pneumonia in which the kidneys, liver, spleen and heart were not infrequently implicated Among the objections which had been raised to this disease being one of the essential fevers was, that in the latter there was a diminution in the quantity of fibrin in the blood, while in pneumonia there was an enormous increase of fibrin But Andral had shown that the same thing was true of variola in the early stage Again, it was objected that pneumonia predisposes its victim to a recurrence (not a relapse), but the same thing was true of cholera, erysipelas, diphtheria, and other similar affections Having referred to the fact that the investigating committee of the British Medical Association had reported that cases of pneumonia have been observed in which it was impossible to detect any breath in the lung, he said, in conclusion, that the labors of Jurgensen, Eberth, Leyden, and others, including our own Flint, had so far established the true nature of this disease that it could no longer be doubted that it was *really an essential fever*

Dr Ross said that at the present time he thought the majority of practitioners would pronounce pneumonia to be a local disease of the lung For himself, however, the more he saw of it the more and more convinced he became that it was undoubtedly constitutional Thus, it selected by preference certain ages and conditions, and there was no ratio, as a rule, between the severity of the attack and the amount of pulmonary tissue involved, except in those cases where a very large amount was implicated, where the damage to so extensive a portion of the lungs might by mechanical means produce disastrous results Ordinarily, the fever and constitutional disturbance were the elements to be taken into consideration, and, when the temperature fell, the whole aspect of the disease was changed The patient was then on the high road to recovery, notwithstanding the fact that a physical examination showed that the local trouble was as serious as ever, or even more aggravated than before The case might be different in pneumonias which followed an injury or occurred in connection with some long-continued pathological condition, but Dr Frederick Roberts, who did not himself believe that the disease was an essential fever, expressly states that such attacks are not those of acute croupous pneumonia Dr Ross went on to say that whenever in the latter affection we find the fever not too high and the pulse moderate, we can look for a good result, notwithstanding the condition of the lungs Again, the kind of treatment which is most efficacious is that required for a constitutional rather than a local disorder The common selection of the right lung also strongly points to a constitutional origin, just as the intestinal lesions in typhoid fever do In the same way it is noticed that the eruption of variola constantly appears first upon the face, and that it shows a special preference for the molar portion of the latter Diphtheria and scarlet fever, as well as other constitutional affections, also have their peculiar local manifestations In conclusion, he remarked that a disease which had the essential features of a continued fever, which could not be artificially produced, and in the treatment of which the condition of the heart was more of a guide than the lungs, ought rightly to be classed among the continued fevers

Dr E G Janeway spoke on the vexed question "What facts and rational grounds, with our present knowledge, can be cited in support of the doctrine that acute local pneumonia depends on the presence of a specific micro organism?" Having stated that he had been prevented by a severe attack of the disease in question from making a number of personal investigations which he had contemplated in connection with the present discussion, he proceeded to refer to the labors of Klebs, Eberth, Leyman, Friedlander and others, in establishing the identity and etiological efficiency of the pneumo coccus While expressing his conviction that this microbe was really the causative agent in pneumonia, he thought it well to call attention to the fact that Dr George M Sternberg, U S A, had recently claimed that the pneumonia-coccus of Friedlander is identical specifically with a micro coccus previously described by himself, which is commonly found in normal human saliva Dr Sternberg, however, had not, it seemed, made any parallel cultures of the two microbes In conclusion, Dr Janeway stated that three days before the meeting he had injected three rabbits with an old pneumonia culture, and that one of them died The examination showed that there was inflammation of both pleuræ, and that the lung on the side of the body which had been injected was inflamed and solidified, while the other lung was collapsed and exhibited petechial points through its tissues There was, therefore, undoubtedly septicæmia with pneumonia (The specimen was exhibited) The other rabbits are still alive, but one of them was ill and likely to die A strong case, he said, could be made out in favor of the pneumo coccus as the cause of pneumonia The question was, Is the pneumonia obtained by experimentation with this a fair representation of pneumonia as it occurs in the human subject? The nature of the proof demanded for the pneumo coccus is the same as for microbes in the other affections, viz 1 The disease-exciting germ must be proved constantly present during the presence of the disease, or at least of its earlier stages 2 It must admit of cultivation out of the body under such circumstances as to assure us of its purity 3 Re introduced into the system, it must excite in susceptible individuals the same disease phenomena 4 In the individual so made ill by the introduction of the cultures we must again find the same germs as the cause

The third question, "What conditions incident to acute lobar pneumonia tend to render the disease fatal?" was discussed by Drs W H Robb, of Amsterdam and H M Biggs, of New York The former said that statistics showed that the average mortality was one in five, and that the disease was especially fatal in the very old and the very young It was more fatal in negroes than whites, and in the female than in the male, the mortality figures in the two sexes bearing the relation of three to two in Vienna Pregnancy also increased the danger from the disease, and it was more fatal when it attached to the upper lobe of the lung than the lower Recovery was very doubtful when the whole of one lung was involved, and in double pneumonia recovery was the exception In chronic drunkards the danger was nearly doubled, and it was also great in cases with such complications as endocarditis, pericarditis, and emphyzema It was also noticeable that the disease was more fatal in some years than in others When the pulse reached 130 or 140 and remained thus rapid for any length of time, the case generally ended fatally, and an intermittent pulse indicated great danger A temperature of 105° or over was a bad sign, and muttering delirium and subsultus tendinum were usually of fatal import Dr Biggs stated that in acute pneumonia the tendency was to recovery, and when this did not occur the fatal issue to be referred to other conditions complicating it Among them were the existence, (1) of some unfavorable condition as regards habits, constitution, age, etc, (2) of some other acute or chronic disease, (3) of certain complications developed in the course of the disease, (4) of the involvement of more than one lung, and (5) of intense activity of the morbific principle Inquiring whether it was possible to trace any circumstance which was common to all the different conditions rendering the prognosis bad, he said that he believed it was, and this was heart failure He considered pneumonia as an essential fever which has its local manifestation in the lung, which is infectious in the same sense that typhoid fever is, and which is due to a specific cause

In discussing the fourth question, "Are there known remedies or therapeutic measures capable of arresting the disease, or of exerting a curative influence by either shortening its duration or conducing in any way to a favorable termination?" Dr T F Rochester, of Buffalo, advocated with much earnestness the special efficacy of carbonate of ammonia, the advantages of which he had first learned when serving in the hospital in, 1848, under Alonzo Clark and John T Metcalfe It was important that the solution should be made from the freshly prepared crystals, and that it should not be kept in the form of powder He advised that it should be used in doses of from five to ten grains every two hours, and that it should as a rule be given in milk In the old and debilitated as much as ten grains every hour might be required With the carbonate of ammonia he usually employed about five grains of Dover's powder, or an eighth of a grain of morphine, every four hours When alcohol was indicated, it was sometimes wonderful to see what it could accomplish, and a highly nutritious diet was always of service He did not believe in the use of the arterial sedatives, but digitalis and convallaria were sometimes of service in stimulating the heart's action Quinine, kairin and antipyrin were also useful, but he thought that the employment of the latter might be carried too far

The fifth question was, "Is blood-letting ever indicated in this disease, and if so, what are the circumstances indicating and contra-indicating this measure of treatment?" and it was discussed by Dr Simon T Clark, of Lockport Possessed of a strikingly handsome presence, a clear and well modulated voice, a graphic style of writing and no little elocutionary power in delivery, Dr Clark undoubtedly made the oratorical hit of the evening, being listened to with profound attention and frequently greeted with hearty applause Believing that the disease was an inflammatory affection, he said there was ground for supposing that, like any other inflammation, it might originate from a variety of causes In the course of his remarks he stated that the experience of physicians in large city hospitals should not be accepted with too much confidence by country practitioners as always applying to their own patients, and related two cases in which he was confident that he had saved life by the use of the lancet One case, in which he drew sixteen ounces of blood, was that of a robust young man whose system was overwhelmed with complete stasis at the commencement of an attack of pneumonia, and the other, in which he drew somewhat less than eight ounces, was that of an Irish woman 60 years of age, accustomed to hard manual labor, who was suffering from passive pulmonary œdema on the fifteenth day of the disease, stimulants producing no effect whatever, and death apparently being imminent These two conditions, he believed, were indications for the infrequent but judicious use of the lancet, and the result was the test of its efficacy

Drs John Shrady, of New York, and E D Ferguson, of Troy, discussed the sixth question, "Is alcohol useful in the treatment of acute lobar pneumonia, and if so, what are the indications for its use, and how is its use to be regulated as regards the quantity given, etc ?" Dr Shrady said that the faith in the efficacy of alcoholic stimulus was too deeply rooted to be disputed, but he believed that it was overrated It was supposed that the more rapid the pulse the greater the need of alcohol, and that it was especially indicated in intermittent pulse Still it was only a forlorn hope He did not believe that it had the effect of lowering the temperature In cases where it seemed to be required from four to eight ounces of spirits a day would usually prove sufficient, and he thought it was best to give it in the form of milk punch Dr Ferguson said that he was not aware that a comparison of two sets of parallel cases, in one of which alcohol was used, and in the other not, had ever been made Having referred to a number of authorities, he said that it could not be doubted that there exists a general opinion that alcohol is of service in quite a large per centage of cases of pneumonia In some cases the increased tolerance of alcohol was quite remarkable In others, its use was attended with extreme danger There was no reason to doubt that alcohol was decomposed within the human organism, and being thus a generator of force, must therefore be regarded as a food It was of special service in cases where the time required before ordinary food could be digested would lead to a fatal result, the alcohol furnishing energy without any demand upon the tonus of the body It temporarily increased the strength of the heart muscle, and he believed that it also acted as an antiseptic He had not been able to find contra-indications to the use of alcohol in moderate doses in in any cases of pneumonia, and he was at a loss to understand the feeling against it If the censure was upon the immoderate use of this agent, as well might we inveigh against the immoderate use of arsenic or opium As a rule alcohol should be given at frequent intervals, as the effect on the heart was evanescent, and he thought that from one half to one ounce of whisky, repeated every one or two hours, was required

The discussion was resumed on the second day, when Dr C G Stockton, of Erie county, read a paper on the seventh question "To what extent is it safe and useful to employ antipyretic measures of treatment in cases of acute lobar pneumonia, inclusive of the cold bath, spraying the body, or the wet sheet?" With the possible exception of cold sponging, he condemned the use of external antipyretic measures The selection of an internal antipyretic, he thought, should be made according to the indications of the case As to antipyrin, he believed that it should never be given in doses larger than 20 grains, nor at intervals of less than eight or ten hours

The eighth and last question "Do relapses of acute lobar pneumonia ever occur during or shortly after convalescence, and does this disease involve any special liability to other diseases, or sequelæ?" was discussed by Dr J G Orton, of Binghamton, who stated that he had never seen an instance of such relapse, and did not believe that they ever occur, the so called relapses being merely due to complications or the involvement of a new portion of the lung Bronchitis, pleurisy, acute nephritis and pericarditis were likely to result indirectly from pneumonia, and one attack of the latter disease predisposed to subsequent attacks Some general debate then brought this memorable discussion to a close P B P

NECROLOGY

ALONZO T KEYT, M D

Dr A T Keyt, of Cincinnati, died at his home in that city on November 9, of cardiac paralysis He was born in Higginsport, Ohio, January 10, 1827, and was therefore in the 59th year of his age While he was a boy his parents moved to Moscow, Ohio After graduating at Felicity, he went to Cincinnati as a medical student, and attended the Ohio Medical College, and, upon attaining the highest honors at that institution, was appointed resident physician at the Cincinnati Hospital with Dr M T Carey After his marriage, in 1849, he settled in Moscow, but soon returned to Cincinnati, where he built up a most enviable practice and reputation

Dr Keyt was devoted to his profession, and was an eminent writer on medical subjects, having been a valuable contributor to the *Boston Medical and Surgical Journal*, *New York Medical Journal*, *The Cincinnati Lancet and Clinic*, The Journal of the American Medical Association, and the *London Lancet* He was the inventor of the compound sphygmograph, which bears his name (Keyt's Cardio sphygmograph)—an instrument for recording at once the beating of the heart and the pulse, which received in its infancy the hearty endorsement of Marey and other leading scientists engaged in the development of graphic methods of investigation He was a patient, laborous and conscientious worker He never submitted anything to the medical press until after repeated trials he was fully convinced of the correctness of his conclusions Through his writings Dr Keyt was better known in Europe than in his own country, his contributions to scientific journals on the sphygmograph, and its use, were quoted as authority One of his last contributions to medical literature, if not his last, was a paper on "Cardiography," read at the meeting of the American Medical Association, last spring, and published in The Journal of August 8, 1885

Dr Keyt was a hard worker, and had been for the thirty-five years he had practiced medicine

The post-mortem examination, as made by Drs Dunn and Isham, showed death to have been due to overwork

MISCELLANEOUS

National Conference of State Boards of Health—In accordance with a resolution adopted at its organization, The National Conference of State Boards of Health will hold its regular annual meeting at the Willard Hotel, Washington, D C, December 8, 1885 For the convenience of the many sanitarians who may desire to attend both, the annual meetings of the Conference are held at the same time and place as those of the American Public Health Association, but its sessions are so arranged as not to conflict with the work of the latter organization With this idea in view, and at the suggestion of the President, the preliminary session of the Conference will be called to order at 9 A M, December 8

Members proposing to present papers to this meeting are requested to send early notice to the Secretary,

J N McCormack, M D

Bowling Green, Ky

Yellow Fever Inoculation —We learn that Dr Joseph Holt, of New Orleans, has received a letter from Dr J McF Gaston, of Atlanta, Ga, inclosing a communication from Dr Domingo Freire, of Rio de Janeiro, giving interesting information about inoculation for yellow fever Dr Freire stated that he had this year performed nearly 5,000 inoculations, the result of which proved an absolute success, for none of those who were inoculated died, whereas over 400 persons who were not inoculated have already succumbed to the disease The inoculated persons dwelt in the same infected quarter, and a great number inhabited the houses wherein deaths had occurred

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT U S ARMY, FROM NOVEMBER 14, 1885 TO NOVEMBER 20 1885

Capt F W Elbrey, Asst Surgeon, sick leave of absence further extended six months on surgeon's certificate of disability (S O 263, A G O, Nov 14, 1885)

Capt Norton Strong, Asst Surgeon, relieved from duty at Ft Union, N M, and ordered for duty as attending surgeon, Hdq'rs Dist of New Mexico, and post surgeon Ft Marcy, N M (S O 171, Dept Mo, Nov 16, 1885)

First Lieut C B Ewing, Asst Surgeon, now at Ft Leavenworth, Kansas, ordered to proceed to Ft Reno, Ind Ter, and report to commanding officer for temporary duty in the field (S O 170, Dept Mo, Nov 13, 1885)

OFFICIAL LIST OF CHANGES IN THE MEDICAL CORPS OF THE U S NAVY DURING THE WEEK ENDING NOVEMBER 21, 1885

M C Drennan, Surgeon, ordered to training ship "New Hampshire"

H Aulick, Surgeon, detached from training ship "New Hampshire," and wait orders

H H Fitts, Asst Surgeon, ordered to appear before Examining Board preliminary to promotion

C W Rush, P A Surgeon, granted sick leave for three months from Nov 20, 1885

CORRIGENDA

In the Journal of October 3 p 387 second column in giving the conclusions of the paper on Natural and Ideal Cholecystotomy by A C Bernays M D of St Louis for The paper concludes with the following propositions" *et seq* read

Having now arrived at the end of the work I may be permitted to offer my own conclusions and I respectfully submit them as follows

I The causes which indicate an operative interference with the system of gall vessels are *a* jaundice *b* paroxysmal pain or a tumor in the right hypochondriac region *c* suppuration *d* peritonitis these conditions to be either severally or singly recognizable the presumable origin being biliary calculi *e* malignant disease

II Explorative laparotomy must be preferred to acupuncture or aspiration as a diagnostic measure

III The incision in the linea alba is preferable when there is much doubt regarding the seat of obstruction because the large ducts can be reached much better from this incision than from the incision parallel to the free border of the ribs

IV The escape of bile through an abdominal fistula is not injurious to the process of normal digestion The bile is an excretion and probably of no more use in the intestinal canal than the urine in the bladder

V Jaundice when caused by an obstruction of the common duct is no contraindication to natural cholecystotomy We may often save life by its early performance

VI Cholecystotomy natural and ideal and cholecystectomy are the three operations at our service cholecystenterostomy may be useful but it has not yet earned a place among approved snrgical procedures

VII Ideal cholecystotomy is indicated when the bladder is normal in structure and when the gall ducts have been cleared of obstructing calculi

VIII Natural cholycystotomy is indicated when the bladder is ulcerated or suppurating or when there are permanent obstructions beyond reach at the time of operation

IX Cholecystectomy should be limited to cases of otherwise incurable or malignant disease of the gall bladder

In my paper upon The Rational Treatment of Pulmonary Diseases by the Pneumatic Cabinet" published in the Journal of Nov 14 1885 I mention a case reported by Dr V Y Bowditch before the Suffolk District *Medical Society on Nov 11 in which bacilli had been seen to disappear* from the sputa and I *inferred* from conversations I had had with Dr B that the treatment employed had been the Pneumatic Cabinet. As soon as I learned my mistake—that the patient had never been under this treatment—I telegraphed to have the paragraph omitted but I was too late—the unfortunate sentence was already in print In justice however both to Dr Bowditch and myself I wish to make this public correction of my error—an error as Dr B kindly writes me such as anyone might easily have made

RECURRENT LARYNGITIS AND OBSTRUCTION OF THE NARES, OR ORDINARY CATARRH[1]

BY E FLETCHER INGALS, A M, M D,

PROFESSOR OF LARYNGOLOGY IN RUSH MEDICAL COLLEGE AND OF DISEASES OF THE THROAT AND CHEST IN THE WOMAN'S MEDICAL COLLEGE CHICAGO

By the term "recurrent laryngitis" I have designated a common form of chronic catarrhal inflammation of the larynx, which, because of its clinical history, etiology, and treatment, merits special attention This is not a distinct affection, and what I have to say of it is not entirely new, but many facts regarding it have been so generally overlooked by authors that I feel confident they will be of interest to this Society The affection is characterized by frequent recurrence of irritation of the larynx, with hacking or hemming cough, and more or less complete aphonia, interspersed with longer or shorter periods of perfect health, or of such slight impairment that the function of the larynx is perfectly performed for all ordinary use of the voice

The affection is usually associated with chronic pharyngitis, and in a large majority of cases with considerable obstruction of the nares, which I believe stands in a causative relation to both the pharyngeal and laryngeal disease It is more frequently met with along the seaboard and on the borders of our great lakes than in inland localities In the cities located on our lakes it affects more frequently those who live within a few blocks of the shore than those half a mile distant, however, no locality is entirely exempt, and frequently the affection is observed in the most unexpected quarters, where the temperature and humidity of the atmosphere are free from the sudden changes which occur near large bodies of water This fact is of importance as one of the proofs of the theory which I hold regarding the etiology of the affection

Most frequently patients are troubled during the fall and winter months, though the changeable weather of spring is quite likely to excite a subacute or chronic inflammation, which, however, may be relieved by the warm days of summer, and is therefore less persistent than similar attacks during cold weather

I have observed the affection most frequently in patients between the ages of 18 and 50 years, and am led to believe that it is not very common before or after these ages Among those who use the voice considerably in speaking or singing, the affection is more frequently observed than in others, but this may be partially due to their noticing imperfections in the vocal organ more than those who only use it for ordinary conversation Men seem more subject to the disease than women, which may be readily explained by the greater exposure in the former, and especially by the common habit of smoking, which is so obnoxious to sensitive mucous membranes

Patients suffering from recurrent laryngitis are usually found to be also affected with coryza and pharyngitis

Examination of the larynx will show the epiglottis and arytenoids moderately congested, and the vocal cords of a light pink color Sometimes the congestion is confined to the edges of the cords only, sometimes to the anterior or posterior extremities, sometimes it is uniform, and in other cases only small patches and enlarged vessels can be seen Occasionally the cords are quite red, in which case they are usually considerably thickened and partially hidden by little masses of mucus adhering to their surface In cases in which the vocal cords are only pink in color, they are seldom thickened to any considerable extent, but upon phonation their edges seem less tense than natural, and often a chink, from one to two millimetres in width, will remain between them even in sounding a high pitched "A"

Frequently we will observe, running from the vocal processes backwards and upwards upon the arytenoid cartilages, small triangular spots from three to six millimetres in width, and five to eight in altitude, in which the color is yellowish or yellowish white These spots have the appearance of superficial ulcers, but are usually only patches of atrophied mucous membrane similar to that which is often seen over the cartilaginous septum in chronic rhinitis In some cases the inter-arytenoid fold of mucous membrane has a slightly granular appearance, and is of a light color, suggestive of superficial ulceration, but true ulceration is uncommon In patients whose vitality is low ulceration may actually take place in either of these places Usually there is little, if any, thickening of other portions of the larynx than the vocal cords.

The posterior pharyngeal wall is usually studded with several enlarged follicles, as in simple chronic follicular pharyngitis, and in the great majority of cases it will be found that there is bending with thickening of the septum narium, or swelling and hypertrophy of the turbinated bodies on one or both sides

---

[1] Read before the Illinois State Medical Society on May 20, 1885

A rhinoscopic examination of the naso pharynx will reveal usually a relaxed and swollen condition of its mucous membrane, and often submucous thickening, giving rise to grayish projections from the sides of the vomer near its posterior edge This thickening is sometimes sufficient to nearly occlude the posterior part of the nasal cavity Often the posterior ends of the inferior, and sometimes of the middle turbinated bodies are so swollen as to greatly restrict the size of the choanæ

Etiology —Most patients have no well defined idea of the cause of the trouble, but experience has shown that usually either hereditary influences, changeable climate or syphilis predispose to the affection, while a great variety of conditions may excite the attack The exciting cause is sometimes found in the over-use of the voice, as in shouting, speaking or singing, particularly in damp, chilly air Sometimes an ordinary cold taken by any of the usual methods, and added to from time to time, will terminate in laryngitis, which will speedily recur upon slight exposure The use of alcoholic stimulants frequently causes the disease, and among men smoking tobacco, and apparently chewing, keeps the mucous membrane in an irritable condition, which favors inflammation, or retards recovery

Pathology —In nearly all of these cases it will be found that there is some permanent obstruction in the nares, such as a deflected or thickened septum, or swelling or hypertrophy of the turbinated bodies, which is responsible for the continuance of the disease In some, mucous polypi exist, and in others rhinoliths or foreign bodies, the effect being the same whatever the character of the obstruction

The obstruction interferes with the free passage of air through the nose, and thus with each inspiration causes rarefication of the air in the posterior nares, this causes congestion and finally inflammation of the mucous membranes, which gradually extend towards the larynx At the same time, from inability to breathe freely through the nose, the patient, particularly when asleep, breathes through the mouth, causing dryness irritation, and finally inflammation of the pharynx and larynx, which may be aggravated, or maintained, by any of the causes already mentioned

As objections to the theory that obstruction of the nares causes nearly all the cases of recurrent laryngitis, it may be claimed that when the obstruction is due to temporary swelling the inflammation should disappear at once when the swelling subsides, and that when due to permanent obstruction it would never disappear while the obstruction continued In answering the first of these objections, I may state that the laryngitis does speedily disappear, time after time, with the subsidence of the swelling, but that finally the membrane becomes so changed by frequent inflammation that it is difficult for nature to restore the healthy processes promptly, or to maintain them when restored even against slight irritation The second is answered by the statement that there is a constant variation in the permeability of the nares, even when obstructed by large mucous polypi, or a greatly distorted or thickened septum These variations, which result from disturbance of the vaso motor nerves, are due mainly to the condition of the atmosphere, the mucous membrane being swollen and the nasal cavities consequently small in damp or chilly weather, and the reverse in the opposite condition of the atmosphere Therefore, during the dryer portions of the year, the nares are frequently sufficiently patulous, notwithstanding the obstruction, to allow free nasal respiration

Clinical History —The symptoms of recurrent laryngitis are like those that mark the course of chronic laryngitis of a mild type, such as hoarseness, tickling in the throat, hacking cough, and expectoration at times of pellets of mucus, with sometimes short spasms of the larynx, due probably to the irritation of dried secretions becoming detached and lodging in the glottis

The hoarseness is not constant, though it is generally apparent if the patient attempts to sing Any of these symptoms may be absent These symptoms are present in greater or less degree with each recurring attack, and they tend to gradually increase in severity until finally they become permanent, as the disease merges into persistent chronic laryngitis

Usually, the history of such a case will extend over several years, and almost invariably the patient will state that he has been troubled with catarrh for two or more years preceding the exposure or indiscretion which excited the laryngeal inflammation And he has generally experienced several similar attacks of from two to four weeks' duration before the fear that the disease may extend to the lungs, prompts him to seek advice Usually no constitutional symptoms attend the affection, though if it passes into chronic laryngitis grave symptoms may be developed, which are due to fatigue and loss of rest caused by the cough

Diagnosis —The history of the case and the discovery of the congestion of the larynx already mentioned, with the appearance of the pharynx and nares, renders the diagnosis certain when pulmonary and cardiac disease have been excluded

Prognosis —The tendency of these cases is to grow worse for two, three, or four years, the larynx becoming more and more sensitive, so that it is affected more easily by slight causes, and the inflammation remains longer and longer with each attack, until finally what I have termed recurrent laryngitis terminates in persistent chronic inflammation which is difficult to eradicate But in some cases the patient learns so well the exciting causes of cold that, by the greatest care, he avoids many attacks, and finally recovery may take place, although the singing voice is likely to be ruined This so called recovery is particularly likely to take place when the inflammation of the larynx is due to hypertrophy of the nasal mucous membrane, a condition which tends after a few years to terminate in atrophy, when the nasal cavities again become free, and unless the structure of the laryngeal mucous membrane has been too much altered by repeated inflammation, the laryngitis will subside Unfortunately, however, even in these cases, atrophy of the nasal tissue may go on to such an extent as to destroy the proper warming function of the nasal chambers, and thus the pharyngeal, and following it the laryngeal inflammation is likely to again recur, and to remain permanent.

There is a belief among many that this affection tends to terminate in consumption, but although I am well aware that it occasionally precedes this disease, I do not think it stands in a causative relation to it. From my observation and reading I conclude that a large proportion of cases of recurrent laryngitis will, if imperfectly treated, result in chronic laryngitis, a limited number will perfectly recover, some will recover for a time, to eventually terminate in a more obstinate affection, and a small number will materially shorten life.

Treatment.—The treatment, to be effective, must be varied according to the cause of the disease. In cases in which the affection occurs in a person predisposed to inflammation of the mucous surfaces, and in which there is no obstruction in the upper air passages to account for it, we adopt the ordinary treatment recommended for chronic laryngitis, *i. e.*, local applications of astringents and stimulants, together with proper attention to any constitutional symptoms. We must make every effort to ascertain the true cause of the frequent colds from which these patients suffer, and they must be advised accordingly.

During the height of the attack, I prefer applications of the sulphate or chloride of zinc, in strength varying from gr. 2 to 30 in f℥i, according to the effect, the weaker solutions during the height of the affection, and the strong ones later on. These are made with the atomizer, if possible, but in a large number of cases, the patient cannot hold the throat in position long enough to permit of a thorough application, and then either a brush or a pledget of cotton must be employed. I prefer the latter for most cases. After the inflammation has subsided, I direct the patient to continue the use of the mild stimulating spray two or three times a day for many months, in order to toughen the membrane so that it may not be so easily affected by exposure. For this purpose I usually recommend a solution of sulphate of zinc in water, 2 or 3 grains to the ounce. This should be used for three or four weeks, and then substituted by some similar remedy, as ferric alum or chloride of zinc, for about the same time, after which the original spray may be again employed. Frequently I combine with these solutions small quantities of carbolic acid, for its sedative effect, and often I add to them the distilled extract of hamamelis, eucalyptol or Listerine. At the same time, owing to the pharyngeal trouble, troches of krameria, or Hancock's compound troches of krameria, or benzoic acid may be beneficially employed four or five times a day. By this process, eventually, nearly all these cases will be cured, if the patient is faithful in the use of his home remedies.

The vapor inhalations which were much in vogue a few years ago are not generally beneficial, except during the first few days of the attack, on the contrary, they are often hurtful by reason of the increased tendency to inflammation induced by the frequent applications of warmth and moisture. As a matter of course the patient must not use the voice when hoarse, and he must be careful in recommencing its use after a period of rest.

The condition of the digestive and secretory organs must be carefully attended to in all these cases, and the rheumatic, gouty, syphilitic, or dartrous diathesis, if present, must receive proper consideration.

In a considerable number of cases, the inflammation is caused and maintained by the use of tobacco. I have found the condition most frequently among smokers, though I believe that chewing is almost as injurious in some individuals. In such cases, tobacco must be discontinued before we can hope for a complete cure.

Mechanical Obstructions.—In most cases, obstruction in the naso-pharynx or nares will be found to exist, and then no remedies are likely to be of much service until the obstruction has been removed. Among the causes of obstruction are foreign bodies, naso-pharyngeal growths, nasal polypi, deflection of the septum with thickening, and swelling with hypertrophy of the turbinated bodies.

When hypertrophy of the palatine tonsil is sufficient to interfere with nasal respiration, the gland must be removed. This may be done with chemical escharotics, the galvano cautery, or with the curette or cutting forceps. Of these methods, the only one I can recommend is the last mentioned. The action of chemical escharotics cannot be well controlled in this locality, and they cause great pain. Removal by the galvano-cautery is painful and tedious. Removal by the curette is more difficult and is likely to be less thorough than by the forceps. The cutting forceps of Lowenberg, or some modification of it, I have found most satisfactory. Usually from three to five applications of the forceps will be necessary, and each will cause considerable pain, therefore it is best to anæsthetize the part with hydrochlorate of cocaine, or in children to produce general anæsthesia. In the latter case, the child is placed on its abdomen, with head drawn over the edge of the table, and the mouth kept open by a suitable gag. The operator sits on a low stool in front and directs his forceps with the forefinger of the left hand, taking special care not to sieze the projecting end of the Eustachian tube.

Polypoid growths springing from the vault of the pharynx, or from the choanæ, may be best removed with the galvano-cautery or steel-wire écraseur, the latter being far preferable in the majority of cases. If the tumor is not large, it may generally be most easily secured by passing the same through the nares, the rhinoscopic mirror being employed to see when the wire is in proper position.

If the tumor be large, a catheter is passed through the nares and the end of it brought out at the mouth. The ends of a wire about three feet long are then passed into the mouth through the catheter, and brought out at the nostril. The catheter is then withdrawn, the ends of the wire slipped through the tube of the écraseur, and the loop drawn back into the mouth and carried up behind the tumor, after which the wire is fastened to the instrument and the tumor is gradually cut off In carrying the loop up behind a large tumor, the operation may be greatly facilitated by using my snare applicator[1]

Mucous Polypi —Nasal polypi may be removed by various methods, the principal ones being by the forceps, the galvano cautery or steel wire écraseur I much prefer the last Whichever plan of operating is adopted, it should be done under a strong light thrown into the nares from a concave reflector

The écraseur causes much less pain than the forceps, and with it we do not remove the turbinated bodies, as frequently happens when forceps are employed After the polypi have been removed, the spots from which they have grown will sometimes need to be cauterized, preferably with the galvano-cautery or chromic acid

Deflected or Thickened Septum —When the trouble depends upon a deflected septum, with more or less thickening, the bend must be straightened and the redundant tissue removed In nearly all cases of bending of the septum there is a considerable outgrowth from its bony or cartilagenous portion which is generally found on the convex side, and in most cases the inferior turbinated body on the other side is hypertrophied The projecting portion of the septum is found with about equal frequency on the right or left side, and in about ninety per cent of the cases, is mostly located on the bony septum, though the cartilaginous septum is probably the first part involved In about ten per cent of the cases the cartilaginous portion causes the chief obstruction

The remarkable relief experienced by patients after removal of obstructing portions of the septum is one of the most satisfactory results ever witnessed by the surgeon Even when small obstructions have been removed the patients remark, "I never knew what it was to breathe before" In more pronounced cases they express themselves as "proud of their nose," and state that no one can appreciate what a "luxury it is to breathe through thé natural channel" In the treatment of these cases I can say nothing whatever in favor of the old method of puncturing the septum, which does not relieve the obstruction, but furnishes a new source of annoyance from the scabbing which occurs When there is only moderate flexure without thickening, the method adopted by Prof Moses Gunn may be followed He recommends oblique crucial incisions so as to allow the cut edges to glide over each other as the septum is forced to its former position, where it is retained by a plug until adhesions take place

This operation is not applicable where there is thickening, or where the vomer is much involved Such cases (and they constitute the greater number) require removal of the redundant tissue In removing this, I formerly dissected off the mucous membrane from below, leaving its attachment above, and then removed as much of the mass as was necessary to restore the normal size of the cavity, but the dissection was a tedious process, and I learned by experience that it was unnecessary, except when the tissue to be removed was near the nostril In other cases healing takes place almost as rapidly and quite as surely and perfectly, if no effort is made to save the mucous membrane Now I saw off the spur, mucous membrane, bone, and cartilage together, on the normal plane of the septum, so that when the piece is removed the nares will be of normal size When this has been done, if there is much bending of the septum it is straightened with forceps, and held in position by a plug or tube of gutta-percha, which may be worn constantly for a couple of weeks, and at intervals for two or three weeks longer, until the parts are fixed in a proper position Sometimes, where the flexure is great, this cut will open into the opposite nares, but usually the mucous membrane of the opposite side is not cut through However, when it is, the opening generally heals, though if it should not, it would be a matter of little consequence, provided the cut was far back on the septum

If the opening be near the nostrils it might, as already suggested, become a source of much annoyance Therefore in this position, care should be taken to save sufficient mucous membrane to cover it After this operation the nares should be kept clean and thoroughly disinfected This may be accomplished by washing with Dobell's solution or soda, and subsequently applying a powder of iodoform, but a pleasanter method and quite as effective is to have the nares sprayed two to four times a day with a solution of Listerine, ʒj or ʒij to ℥j, which is thoroughly antiseptic and has a pleasant odor The instruments used for the operation are an ordinary phalangeal saw, a small nasal saw, nasal cutting forceps, a nasal spatula, nasal scissors, and forceps for replacing the septum The gutta percha plug may be easily made from the sheets of this material which are used by dentists for making plates for false teeth The parts should be thoroughly anæsthetized by cocaine before the operation, excepting in young children, in whom general anæsthesia will be required

Hypertrophic Catarrh, or in common parlance, catarrh, is by far the most frequent cause of the form of laryngitis now under consideration It is a frequent cause of deafness, and is a source of much discomfort to many people, even when it causes no impairment of the voice or sense of hearing Until recently its treatment has been very unsatisfactory, but happily this is now changed, and we may undertake its cure with almost as much confidence as we could that of a case of intermittent fever

As the symptoms of this disease are due to swelling or hypertrophy of the mucous membrane, and sub-mucous tissues, some plan must be adopted which will prevent the one and remove the other, and I may as well premise what I am to say on this subject by the statement that nothing short of surgical interference will certainly accomplish this end, though many local remedies are of temporary value

The methods which have been recommended for preventing swelling and removing hypertrophied tissue are, cauterization by various chemicals, or the galvano-cautery, and removal by scissors, cutting forceps, or écraseur Of the various chemicals, chromic and glacial acetic acids have been found most useful, but both give considerable pain, though less than other escharotics, and neither has been found entirely satisfactory The usual experience with chemical escharotics is, that the patient is partially relieved, and concludes that what remains of the disease is less disagreeable than the remedy, therefore he discontinues treatment too soon, and after a few months the disease returns Remembering former suffering he does not return to his physician, and the latter, until he hears of the case accidentally, fondly hopes that it has been cured

---

[1] This is an instrument so constructed that as the wire loop is drawn back into the naso-pharynx it may be easily opened and carried up behind the tumor where it is held until the wires have been adjusted to the snare and drawn tight Then the applicator is readily released from the wire and withdrawn

When the swollen tissues are prominent, and mainly confined to the posterior end of the turbinated body, no method is so successful for their removal as that by the steel wire écraseur, various forms of which are now in the market When the anterior portions of these bodies are involved the écraseur, even when supplemented by a perforating needle, is a very unsatisfactory instrument In cases of the latter variety occasionally nasal scissors may be advantageously employed, or, if the bone itself is hypertrophied, nasal cutting forceps with the scissors will be needed In most cases no instrument answers the purpose so well as the galvano cautery, by which horizontal lines may be burned through the soft tissues down to the bone in two or three places with the result of effectually preventing subsequent swelling, and restoring the naris to its normal calibre, whereby free nasal respiration is reestablished Thus the disease is practically cured, though for a time mild astringents or stimulating applications may be needed to restore the normal tone of the mucous membrane After the burning, the nasal cavities should be kept clean by alkaline washes or sprays, to which about ten per cent of listerine has been added A powder composed of equal parts of boric acid and iodoform will be found an excellent application

The instrument which I employ for the cauterization is a large two celled galvanic battery, with carbon and zinc elements, and bichromate of potash solution, a universal handle and a platinum bladed electrode The parts are first anæsthetized with cocaine, so that the burn is made without pain The cocaine has no injurious effects, but care must be taken not to burn too much at once, lest severe inflammation be set up Usually a single line from behind forwards on one side is as much as it is judicious to burn at a single sitting Ordinarily the nares will be stopped for two or three days after the cauterization, and subsequently occasional touching of the part with a solution of nitrate of silver is desirable, to promote rapid cicatrization This mode of treatment, when properly carried out, will surely cure the hypertrophic catarrh, and then the resulting laryngitis will either disappear spontaneously or may be removed by treatment

The results of this treatment on the general condition of the patient are sometimes remarkable Patients, who have for years been so frail that the slightest exposure or over-work would make them sick, will sometimes begin to improve at once as the result of more perfect oxygenation of the blood, and they became hardy and robust, so that it is a frequent occurence after a few weeks for them to remark that they "have not been so well for years " While at first this result seems singular, on second thought it is found to be upon the same principle that a weak person who has for years been confined in poorly ventilated apartments will speedly become vigorous and strong when removed to the pure atmosphere of the country

In cases in which curative treatment can not be carried out, much temporary benefit may be obtained from the repeated application to the nares of cocaine One of the remarkable properties of this drug, which was pointed out seperately and almost simultaneously by Dr Bosworth, of New York, and myself, is that when applied in small quantities to the swollen turbinated bodies, it causes a contraction of the tissue within two or three minutes, which will continue for several hours This will open the nares and allow easy respiration I have employed this drug constantly during the past winter for the relief of acute colds, and in the examinations of hypertrophic catarrh with the most favorable results I employ it in the proportion of 4 per cent of cocaine to 96 per cent of powdered starch or sugar of milk, directing that it be blown into the nares at bed time, and repeated after four or five hours if needed It causes the swelling to disappear at once, checks secretions, and allows the patient to breath easily through the nose, thus preventing laryngeal complications

In conclusion I wish to call attention to the following propositions

1 Recurrent laryngitis is usually dependent upon obstruction of the nasal cavities

2 This obstruction in the majority of cases is caused either by deflection and thickening of the septum or by what is known as hypertrophic catarrh

3 To effect a permanent cure the obstruction must be removed

4 The operative procedures necessary for the removal of these obstructions may be made painless by the use of hydrochlorate of cocaine

5 This method of treatment properly carried out may be relied on to cure the catarrh and the laryngitis which it has caused

6 Great improvement in the general health often results from the removal of the nasal obstruction

7 In acute colds or exacerbations of hypertrophic catarrh, immediate relief may be obtained by the insufflation often as needed of small quanties of cocaine

ANTIPYRIN, ITS HISTORY, PHYSIOLOGICAL ACTION, AND THERAPEUTIC EFFECTS[1]

BY SAMUEL S ADAMS, A M , M D ,

OF WASHINGTON, D C

As the question, "What is Antipyrin?" was asked in this Society one week ago, and not answered satisfactorily, the writer will endeavor, in as brief a manner as practicable, to answer it For a year past the medical journals in this and foreign countries have been discussing the subject, and yet there seems to be a majority of the members of this Society who have acquired no knowledge of the drug

---

[1] Read before the Medical Society of the District of Columbia, October 21 1885

Whenever a new remedy is introduced to the medical profession it meets with many curious experiences Some promptly adopt and try any new drug that may be placed upon the market, especially if the price is high, and use it like a hobby until both their patients and themselves become convinced of its inutility Others, not content with simply ignoring its existence, actually condemn those of their brethren who are bold enough to test its efficacy as a remedial agent A large majority of the profession, however, accept for trial new remedies upon the recommendation of those skilled in physiological and therapeutical research The last class would seem to be the wisest, on account of its willingness to experiment upon such a sound basis If we did not accept the statements of the men we characterize as authorities, how long would it be before we reached the level of empiricism? If these authorities tell us that a certain newly discovered combination of elements has proven, in their hands, a more valuable remedial agent than any hitherto known, then it would seem to be our duty, as scientific humanitarians, to give that discovery a fair and impartial trial, and base our conclusions of its worth upon unbiased therapeutical evidence If we had not accepted the statements of authorities where would cocaine have been to day? Would it not have been consigned to the oblivion some have chosen for antipyrin? It seems to me the plain duty of the profession to try all remedies of recent introduction when they are endorsed by the recommendations and experiments of men who have devoted means, time and labor to discover and demonstrate their chemical, physiological and therapeutic properties

Filehne, who had made previous experiments with kairin, was induced, at the suggestion of several chemists, to experiment upon the physiological and therapeutical properties of dimethyl oxychinoline, an alkaloid discovered synthetically by Ludwig Knorr, assistant in the Chemical Institute at Erlangen Filehne's results were such as to induce him to request his friends in charge of various public hospitals in Germany, to make extensive trials with this drug in the reduction of temperature in various febrile and inflammatory diseases It was also extensively used by Guttmann The results obtained established beyond a doubt that the new drug was a safe and valuable antipyretic of limited powers The deceptive but enticing name "Antipyrin" was given to Knorr's preparation by Filehne With the endorsement of such men as Filehne, Guttmann, Huchard, Coppola and Migazzini, the drug came to America, where the experiments of Draper, Butler, and others, confirmed the statements of its antipyretic value Certainly these facts and endorsements are sufficient to warrant others in further physiological and therapeutical observations with it

We have no reason to doubt the honesty or integrity of Filehne and the various German writers who have endorsed this drug as a legitimate therapeutic preparation When we remember that the discoverer is a scientific chemist, we certainly should not wish to deprive him of any emolument he may derive from its manufacture or sale The reward sought to be obtained from a monopoly may be properly condemned in a physician, but should this rule extend so as to include all persons engaged in business pursuits? A parallel case, and one which possesses a slight shade of quackery, is that of Tanret, the discoverer of pelletierine, whose preparation is recognized by the dispensatories and sold at an exorbitant price by its sole manufacturer Knorr, in taking out his patent, did not seek to place a secret nostrum on the market, but thereby simply secured to himself the right to manufacture a drug discovered by him His formula and mode of preparation are not only open to public inspection but they have, I believe, been published to the world in several languages The following is a copy of the patent granted him by the U S Patent Office

UNITED STATES PATENT OFFICE

Ludwig Knorr, of Erlangen, Assignor to Farbwerke, Vormals Meister, Lucius & Bruning, of Hochst-on-the-Main, Germany

PREPARATION OF DIMETHYL PHENYL OXYPYRAZOL

Specification forming part of Letters Patent No 307,399, dated October 28, 1884.

Application filed March 5 1884 (Specimens) Patented in Germany July 22 1883 No 26 429

To all whom it may concern

Be it known that I, LUDWIG KNORR, a citizen of the Empire of Germany, and a resident of Erlangen, in the Empire of Germany, have invented certain new and useful Improvements in the Preparation of Dimethyl phenyl oxypyrazol, and I do hereby declare that the following is a full, clear, and exact description thereof, which will enable others skilled in the art to which it appertains to make and use the same

My invention consists of a new product, dimethyl phenyl oxypyrazol, from phenyl hydrazine, the latter yielding, as products of a series of observations, new compounds, which I have found to be valuable medicaments

The following is a description of my method of proceeding

By mixing the body well known as acetylacetic ether with a molecular quantity of phenyl hydrazine, water is eliminated, and a condensation product is formed, termed "phenyl dydrazine acetylacetic ether," of the formula

$$C_6H_5\text{—}N.H=\overset{CH_3}{C}\text{—}CH_2\text{—}CO\,C\,H_5$$

When this product is heated to a temperature of 100° to 150° Centigrade, until a sample perfectly solidifies on cooling or on immersion into ether, a mass will result which, after crystallization from water or from some other medium, represents pure methyl phenyl oxypyrazol *Its formation from phenyl hydrazine acetylacetic ether takes place under production of alcohol,* as expressed in the equation

$$C_6H_5N\,HC<\begin{matrix}CH_3\\CH\,CO_2D\,H\end{matrix}=C_{10}H_{10}N\,O+C\,H_5OH$$

When the methyl phenyl oxypyrazol thus formed is heated with methyl chloride, bromide, or iodide, it is readily converted into dimethyl phenyl oxypyrazol

Dimethyl phenyl oxypyrazol is distinguished by the following properties It crystallizes from ether in lamellæ of a pearly luster, melting at 113° centigrade It is soluble in alcohol, water, and acids, from which solutions it is precipitated by concentrated alkalies Its aqueous solution turns red on addition of ferric chloride, and green when a nitrite is added When a concentrated aqueous solution is mixed with the solution of a *nitrite, green crystals separate on standing*

What I claim as new, and desire to secure by Letters Patent, is—

The new product dimethyl phenyl oxypyrazol the result of the process herein described, the same being distinguished by the properties herein mentioned

In testimony that I claim the foregoing as my own I affix my signature in presence of two witnesses

LUDWIG KNORR

Witnesses A S HOGUE, J GRUND

Filehne's observations show that the effect of the drug is gradual and persistent for from five to eighteen hours, the descending curve being also gradual, that in a large majority of cases there were no bad effects, though occasionally there was vomiting, that 75 to 90 grains should be given to adults in hourly doses of 30 grains, that the dose for children should be proportionate to age, that the dose to phthisical and thin people should be small, that the greatest fall of temperature observed by him was to 38 Cent (100 4° F), that the fall begins one and one half to two hours after the first dose, that the decline is usually without sweating, that the rise, after reduction, is not accompanied by chill, that the pulse rate falls with the temperature, that albumin was not in the urine, and that its color was not changed

Guttmann observed that if there was great reduction of temperature there might be sweating, that vomiting was occasional that the temperature fell gradually and continuously, that the maximum fall was in five hours, that the duration of action was from five to eighteen hours, that reduction resulted from a single dose of four grammes, or one gramme doses repeated every hour until five had been taken, that half a gramme or less every hour had no effect, and that the pulse fell with the temperature

Coppola has given the formula of antipyrin as $C_{11}H_{1}N_{2}O$ He says that in frogs the reflex action is due to the action of the drug on the spinal cord, that in larger doses its action is transmitted to the brain, and it produces tetanic spasms which differ from the convulsions of strychnia poisoning either in their mode or their origin, that the frog may remain in this condition twenty four hours, when the spasms cease, that hyperæsthesia lasts for several days, that in lethal doses the nervous system, preliminarily excited, produces death by paralysis, that if a large poisonous dose be given the frog falls paralyzed without any preliminary excitation, that the respiratory movements do not intermit until the advanced stage of poisoning, that in a short time they resume their action even though the frog becomes tetanized, that the heart still beats with considerable vigor after the frog is paralyzed, that the effects are similar in warm blooded animals, that death is produced by paralysis of the respiration, and the heart stops in systole, that it has no action upon motor nerves and striated muscles, that dilatation of the pupil is due to stimulation of the sympathetic, that as an antiseptic it has one thirtieth of the strength of salicylic acid, and one-fifteenth of quinine, that it excites the intracardiac ganglia and also the vaso dilators, and that it increases arterial tension

Hénocque observed that it had considerable hæmostatic power, and that when applied locally its effect was greater than that of perchloride of iron

Alexander says it is produced by the action of acetic ether on aniline A full account of its chemical composition can be found in the report of the German Chemical Society, 1884, xvii, 549

At my request, Dr Louis Kolipinski has made some physiological experiments with the drug, at the Children's Hospital in this city In justice to him it must be said that the conclusions derived from his experiments were drawn before he had examined the German and French literature on this subject

EXPERIMENTS WITH NON-FATAL DOSES OF ANTIPYRIN

In order to determine the physiological effects of antipyrin on animals, in large but not fatal doses, and also to note the variations which may result from quantity of drug and length of time in administration, a healthy male puppy two months old and weighing eighteen pounds, was selected He received by rectal injection 10 grains for three successive hours beginning at 11 A M, and 20 grains for the same periods of time immediately following Thus 90 grains were given by four in the afternoon The temperature was taken by keeping the thermometer bulb for five minutes in the groin The animal was kept confined and was offered food

The pulse, respiration and temperature recorded just before beginning the injections of the drug were 136, 52, 101 3° F The temperature had declined 0 5° F at 1 P M, but stood again at 101 7° F at 2 P M, and 101 5° F at 3 At 2 30 he vomited partly digested food, and at 4 P M there was a full flow of saliva He became very quiet, so that it was not necessary to secure him in making records of body heat, etc His temperature had sunk 0 6° F, the pulse was diminished and the breathing quickened with wheezing expirations He staggered in walking, but was perfectly conscious and intelligent The pupils were moderately dilated and responded to the irritation of light The saliva dripped from the mouth and tenaceous, frothy mucus was repeatedly vomited

At 4 30 P M these symptoms continued The conjunctivæ were very pale, and the gums bluish-white The ventricular action had steadily increased in force At this time the respiration and pulse were both diminished, and the temperature had fallen 0 7° F Saliva and gastric mucus repeatedly tested gave no reaction with ferric chloride

At 5 P M the pulse was the same, the respiration diminished, and the temperature 2 3° F below its primary figure The heart contractions were still powerful Traces of antipyrin were detected in the urine by the iron salt The intensity of the red color given by this reagent gradually increased

At 6 30 the breathing was slow, the pulse increased and the temperature had lost 2 7° F There was moderate hyperæsthesia and a few clonic spasms of the neck and forelegs The dog sought the darkest corner in the room, and would start up and trot about, which act was followed by emesis of a sudden and violent nature Ventricular action remained very strong

At 9 30 P M the gums were of a deep blood-red color, much more intense than their usual pinkish hue The temperature had risen to 100 7° F, pulse the same as at 6 P M, and the respiration at its lowest, 24

At 11 P M perfectly recovered Temperature 102° F, respiration 28, pulse 168

The following is the record with the falls of temperature, heart's action, and breathing

	Temp	Pulse	Resp
11 A M	101 3° F	136	52
12 M	101 4	112	50
1 P M	100 8	120	44
2 "	101 7	80	64
3 "	101 5	88	60
4 "	100 7	120	60
4 30 "	100 5	120	44
5 "	99	120	52
6 30 "	98 6	160	36
9 30 "	100 7	160	24
10 45 "	102	168	28
9 30 A M	101 7	240	48

It is noticeable that the respiratory fall was the last to disappear, and that the pulse, which in the evening had an average of 160, had its minimum of 80 at 2 P M At 9 30 the next morning respiration and temperature were as usual, but the heart had increased to 240 with decided diminution of ventricular force The animal continued playful and with good appetite throughout the day

7 30 P M —Temperature 102 5° F The room in which the experiments were concluded was close and warm (82° F) The heart's action was so rapid and the respiration so panting that the former could not be counted accurately He was given, by rectal injection, 60 grains of the alkaloid At 8 25 full and copious vomiting

8 30 P M —Dose was repeated The heart and respiration now were 160 and 120, the temperature 102 5° F

8 45 —Vomited last of digesting food Antipyrin in the urine

9 20 —Pupils dilated and animal much enfeebled Temperature 102 2° F , respiration 240, heart's action weak There was very marked hyperæsthesia of surface and tonic spasms of limbs on one and on both sides 30 grains were introduced at 9 35 He was still able to run about and mucus vomiting persisted The gums were not so pale as yesterday Pupils mydriatic

9 40 —Killed with chloroform The only noteworthy appearances were spleen unusually dark, stomach actively congested, kidneys pale and normal The bladder held urine rich in urates and antipyrin, and giving no reaction for albumen The right ventricle appeared large and soft as if from overdistension which had existed some short time

The conclusions submitted are

1 In the dog large clinical doses diminish the heart's action with increased ventricular energy

2 A fall in the normal temperature of 2 5° F , which does not result in two hours, although the quantity of antipyrin be $1\frac{2}{3}$ as much

3 Vomiting, hyperæsthesia and tonic and clonic spasms are produced

4 Vomiting is not due to local action on the stomach, and can be caused by a single dose of 60 grains without decline of temperature

5 Antipyrine is eliminated by the urine, and not with the saliva or gastric mucus

6 There is a secondary weakening of the heart

7 There is dilatation of the pupil, probably due to stimulation of the cervical sympathetic

8 There is a secondary enlargement of the calibre of the blood-vessels

9 The fall in the heart beats and increased ventricular energy precede the greatest fall of temperature and respiration

10 The greatest fall in respiration follows that of temperature

May[1] reports the following case of collapse Male, 25, had croupous pneumonia of the left inferior lobe On the third day of the disease the patient was pale and delicate, pulse hardly rhythmic, great prostration Antipyrin was used as follows

At 7 P M T 39 8° (103 6° F), P 108, 2 grammes
At 8 P M T 39 3° (102 7° F), 2 grammes
At 9 P M T 38 3° (100 9° F), 1 gramme

Only slight sweating At 5 A M T 53 6° (96 1° F), collapse, frequent, minimal pulse, extremities cool, and face prominent Recovery from collapse at 1 P M

Barrs[2] reports the case of Blose Female, 35, miscarried at fifth month, confined to bed until about sixth six weeks after entered hospital Now had diarrhœa abdominal pain vomiting, headache and shiverings Became progressively weaker, heart and pulse sounds were normal, turned in bed with difficulty

3 P M , P 132, R 36, T 103° F Antipyrine, 35 grains

6 P M , P 108, T 98 4° F Antipyrin, 18 grains

11 P M , P 132, rectal temp , 98 4° F

Next day —Patient restless during the night, diarrhœa and vomiting, P 120, T 98° F , greatly collapsed 5 P M —No reaction, death at 11 P M , during last half hour T 100 6° F

Sectio Cadaveris —Brain and membranes congested, heart somewhat softened, lungs normal, spleen greatly congested, weight three pounds, softened, and contained a large infarction, kidneys enlarged, two to three conical infarctions

In this case I do not believe death was caused by the antipyrin, but by the diarrhœa and vomiting, which had almost completely exhausted her when the drug was given

My own deductions from experiment, observation and the experience of others regarding this drug, are that antipyrin is not an anti periodic, but simply an antipyretic, that it reduces high temperature, that it may be given in all diseases accompanied by high temperature without regard to their pathological conditions, that it reduces the temperature without apparently affecting the pathological process which increases the body heat, that under its administration, in graduated doses, the temperature falls, but reaches its maximum again in a few hours, that its effects are transitory, that it is rapidly eliminated, that it reduces the pulse and respiration, that its depressing effects need careful watching to preveet collapse, that in case of threatening collapse free stimulation is necessary, that cerebral symptoms improve, that it reduced high temperatures, slowed the pulse, and increased its tension, that it markedly lessened the respiratory movements, that it restored the consciousness from delirium, and that it produced free sweating, that its administration was not accompanied by any alarming symptoms, that there was no vomiting, that its effects did not last longer than six hours, that there was no lowering of the daily maximum temperature, and that there was no appreciable effect upon the course of the disease proper.

---

[1] Deutsche med Wochenschr Berl 1884 X 389
Lancet 1885 I 382

To Dr. Kohpinski and the courteous gentlemen of the library of the Surgeon General's Office, U. S. A., I return my sincere thanks for their valuable assistance in making a complete examination of the bibliography of this subject.

ON THE IDENTITY OF YELLOW FEVER AND ACUTE MALARIA—CONSEQUENT CONTAGIOUSNESS OF MALARIA AND CURABILITY OF YELLOW FEVER[1]

BY VIEIRA DE MELLO, M.D.,

MEMBER OF THE ACADEMY OF MEDICINE OF RIO DE JANEIRO

I

Considering that pathologists and physicians of all countries are of one accord in admitting that "the epidemics of yellow fever are *always* preceded by serious cases of acute malaria," yellow fever must needs then, in my opinion, express the state of *saturation* of the atmosphere by the swamp microbe, thus permitting to man a greater absorption in due time, of the morbific principle, hence the very serious character of the symptoms presented;

Considering that the two morbid entities co-exist in the same zone and increase in direct ratio of the development of the malarious germ,—a fact largely observed at Rio de Janeiro, where yellow fever is a contemporary and a companion of the excavations, breaking out at the same time that these are effected, and following them in their way through the city;

Considering, besides, that yellow fever has no distinct characteristics of its own,—the symptoms that are ascribed to it being *strictly* the same that I have observed in serious cases of acute malaria, hæmorrhage and black vomit *included*;

Considering likewise,—and this argument is of surpassing value,—that, morphologically, the *element* considered as the generator of yellow fever, as drawn by Dr. Domingos Freire, is strictly the same that I have met with in the blood, vomit and urine of *patients suffering from acute and chronic malaria*, this last period of malaria serving exactly to avoid the objections of those who may ascribe to yellow fever a case of acute malaria,—a thing that cannot be even thought of in a chronic case;

Considering, moreover, that this very same element has been *found by me* in the water that is used for drinking by the inhabitants of places where malaria reigns endemically,—places where yellow fever is not even spoken of,—an argument that at once enlightens the etiology of malaria, and overthrows the objections of those who ascribe to pigmental alterations of the hæmatin the elements described by Laveran and confirmed by me;

Considering, finally, that all the cases of malaria that could have been, and those that were classified as yellow fever, and were attended by me, yielded to the specific treatment of acute malaria,—unsuccess in those in which this treatment was employed being due, in my opinion, to insufficient doses, bad quality of the medicine used, or tardy interference, when the organism is no longer in a state to absorb it,—or because the disease is several days old, or, lastly, because the attack has been so violent as to cause the same profound disorders that in milder cases would take time to make their appearance;

I have come to the conclusion that *yellow fever is a graver modality of acute malaria*, its superlative gravity, that, therefore, *it is not an idiopathic morbid entity*, as has been asserted until now, but the expression of gravity in another morbid state, and that the denomination of yellow fever should be substituted by the one of *grave malaria*, this qualification serving to designate the highest intensity of malaria.

II

Amongst the objections that can be made to these doctrines, objections that have already been presented to me, the one that seems most weighty is the following: "Yellow fever cannot be of the same nature as malaria, since the first is contagious and the second not."

This is a great mistake. In the first place, no one, to my knowledge, has been able to demonstrate the contagiousness of yellow fever, that is, the *transmissibility* of the disease from body to body, by *contact*. In the second place, because malaria is susceptible of being transmitted by any individual to persons surrounding him, as well as of being transported to great distances. For example: An individual is possessed by the helococcus (ἑλος, swamp, marsh, and *κοκκος*, in Latin *coccus*, *coccum*, a germ, a seed, a small round body. This denomination, created by myself to designate the microbe of malaria, is based on the rules established by Egger for the construction of neologisms). He retires to his room, where he remains for several days without appropriate medication. The helococcus not being now attacked, and finding in the organism of the patient a favorable field for its development, proceeds on its evolutionary march. The patient, whose emunctory apparatus works, discharges continually from his body a certain quantity of these microbes that are thrown into the surrounding air, where, if they meet with favorable conditions, they live, develop and procreate. Therefore, after a certain time, the rooms of this individual will be transformed into a genuine focus or nursery of helococci, and, consequently, whoever enters there may receive the same morbific element that is found in a marsh or swamp.

And here we have the explanation of the *contagiousness* of "yellow fever," which is at the same time the explanation of the *contagiousness of malaria*, a question that has been despised, why I cannot tell, since it is a known fact, as no one dares to deny, that malaria is a microbiotic disease. Thus, a person who has been infected in a marsh, may, in turn, constitute another *marsh*, focus or nursery, as long as his

	Temp.	Pulse	Resp.
11 A.M.	101.3° F.	136	52
12 M.	101.4	112	50
1 P.M.	100.8	120	44
2 "	101.7	80	64
3 "	101.5	88	60
4 "	100.7	120	60
4.30 "	100.5	120	44
5 "	99	120	52
6.30 "	98.6	160	36
9.30 "	100.7	160	24
10.45 "	102	168	28
9.30 A.M.	101.7	240	48

It is noticeable that the respiratory fall was the last to disappear, and that the pulse, which in the evening had an average of 160, had its minimum of 80 at 2 P.M. At 9.30 the next morning respiration and temperature were as usual, but the heart had increased to 240 with decided diminution of ventricular force. The animal continued playful and with good appetite throughout the day.

7.30 P.M.—Temperature 102.5° F. The room in which the experiments were concluded was close and warm (82° F.). The heart's action was so rapid and the respiration so panting that the former could not be counted accurately. He was given, by rectal injection, 60 grains of the alkaloid. At 8.25 full and copious vomiting.

8.30 P.M.—Dose was repeated. The heart and respiration now were 160 and 120, the temperature 102.5° F.

8.45.—Vomited last of digesting food. Antipyrin in the urine.

9.20.—Pupils dilated and animal much enfeebled. Temperature 102.2° F., respiration 240, heart's action weak. There was very marked hyperæsthesia of surface and tonic spasms of limbs on one and on both sides. 30 grains were introduced at 9.35. He was still able to run about and mucus vomiting persisted. The gums were not so pale as yesterday. Pupils mydriatic.

9.40.—Killed with chloroform. The only noteworthy appearances were spleen unusually dark, stomach actively congested, kidneys pale and normal. The bladder held urine rich in urates and antipyrin, and giving no reaction for albumen. The right ventricle appeared large and soft as if from overdistension which had existed some short time.

The conclusions submitted are:

1. In the dog large clinical doses diminish the heart's action with increased ventricular energy.

2. A fall in the normal temperature of 2.5° F., which does not result in two hours, although the quantity of antipyrin be 1⅔ as much.

3. Vomiting, hyperæsthesia and tonic and clonic spasms are produced.

4. Vomiting is not due to local action on the stomach, and can be caused by a single dose of 60 grains without decline of temperature.

5. Antipyrine is eliminated by the urine, and not with the saliva or gastric mucus.

6. There is a secondary weakening of the heart.

7. There is dilatation of the pupil, probably due to stimulation of the cervical sympathetic.

8. There is a secondary enlargement of the calibre of the blood-vessels.

9. The fall in the heart beats and increased ventricular energy precede the greatest fall of temperature and respiration.

10. The greatest fall in respiration follows that of temperature.

May[1] reports the following case of collapse. Male, 25, had croupous pneumonia of the left inferior lobe. On the third day of the disease the patient was pale and delicate, pulse hardly rhythmic, great prostration. Antipyrin was used as follows:

At 7 P.M. T. 39.8° (103.6° F.), P. 108, 2 grammes.
At 8 P.M. T. 39.3° (102.7° F.), 2 grammes.
At 9 P.M. T. 38.3° (100.9° F.), 1 gramme.

Only slight sweating. At 5 A.M. T. 35.6° (96.1° F.), collapse, frequent, minimal pulse, extremities cool, and face prominent. Recovery from collapse at 1 P.M.

Barrs[2] reports the case of Blose. Female, 35, miscarried at fifth month, confined to bed until about sixth six weeks after entered hospital. Now had diarrhœa, abdominal pain, vomiting, headache and shiverings. Became progressively weaker, heart and pulse sounds were normal, turned in bed with difficulty.

3 P.M., P. 132, R. 36, T. 103° F. Antipyrine, 35 grains.

6 A.M., P. 108, T. 98.4° F. Antipyrin, 18 grains.
11 P.M., P. 132, rectal temp., 98.4° F.

Next day.—Patient restless during the night, diarrhœa and vomiting, P. 120, T. 98° F., greatly collapsed. 5 P.M.—No reaction, death at 11 P.M., during last half hour T. 100.6° F.

Sectio Cadaveris.—Brain and membranes congested, heart somewhat softened, lungs normal, spleen greatly congested, weight three pounds, softened, and contained a large infarction, kidneys enlarged, two to three conical infarctions.

In this case I do not believe death was caused by the antipyrin, but by the diarrhœa and vomiting, which had almost completely exhausted her when the drug was given.

My own deductions from experiment, observation and the experience of others regarding this drug, are that antipyrin is not an anti periodic, but simply an antipyretic, that it reduces high temperature, that it may be given in all diseases accompanied by high temperature without regard to their pathological conditions, that it reduces the temperature without apparently affecting the pathological process which increases the body heat, that under its administration, in graduated doses, the temperature falls, but reaches its maximum again in a few hours, that its effects are transitory, that it is rapidly eliminated, that it reduces the pulse and respiration, that its depressing effects need careful watching to preveet collapse, that in case of threatening collapse free stimulation is necessary, that cerebral symptoms improve, that it reduced high temperatures, slowed the pulse, and increased its tension, that it markedly lessened the respiratory movements, that it restored the consciousness from delirium, and that it produced free sweating, that its administration was not accompanied by any alarming symptoms, that there was no vomiting, that its effects did not last longer than six hours, that there was no lowering of the daily maximum temperature, and that there was no appreciable effect upon the course of the disease proper

To Dr Kolipinski and the courteous gentlemen of the library of the Surgeon General's Office, U S A, I return my sincere thanks for their valuable assistance in making a complete examination of the bibliography of this subject

ON THE IDENTITY OF YELLOW FEVER AND ACUTE MALARIA—CONSEQUENT CONTAGIOUSNESS OF MALARIA AND CURABILITY OF YELLOW FEVER[1]

BY VIEIRA DE MELLO, M D,

MEMBER OF THE ACADEMY OF MEDICINE OF RIO DE JANEIRO

I

Considering that pathologists and physicians of all countries are of one accord in admitting that "the epidemics of yellow fever are *always* preceded by serious cases of acute malaria," yellow fever must needs then, in my opinion express the state of *saturation* of the atmosphere by the swamp microbe, thus permitting to man a greater absorption in due time, of the morbific principle, hence the very serious character of the symptoms presented,

Considering that the two morbid entities co exist in the same zone and increase in direct ratio of the development of the malarious germ,—a fact largely observed at Rio de Janeiro, where yellow fever is a contemporary and a companion of the excavations, breaking out at the same time that these are effected and following them in their way through the city,

Considering, besides, that yellow fever has no distinct characteristics of its own,—the symptoms that are ascribed to it being *strictly* the same that I have observed in serious cases of acute malaria, hæmorrhage and black vomit *included*,

Considering likewise,—and this argument is of surpassing value,—that, morphologically, the *element* considered as the generator of yellow fever, as drawn by Dr Domingos Freire, is strictly the same that I have met with in the blood, vomit and urine of *patients suffering from acute and chronic malaria*, this last period of malaria serving exactly to avoid the objections of those who may ascribe to yellow fever a case of acute malaria,—a thing that cannot be even thought of in a chronic case,

Considering, moreover, that this very same element has been *found by me* in the water that is used for drinking by the inhabitants of places where malaria reigns endemically,—places where yellow fever is not even spoken of,—an argument that at once enlightens the etiology of malaria, and overthrows the objections of those who ascribe to pigmental alterations of the hæmatin the elements described by Laveran and confirmed by me,

Considering, finally, that all the cases of malaria that could have been, and those that were classified as yellow fever, and were attended by me, yielded to the specific treatment of acute malaria,—unsuccess in those in which this treatment was employed being due, in my opinion, to insufficient doses, bad quality of the medicine used, or tardy interference, when the organism is no longer in a state to absorb it,—or because the disease is several days old, or, lastly, because the attack has been so violent as to cause the same profound disorders that in milder cases would take time to make their appearance,

I have come to the conclusion that *yellow fever is a grave modality of acute malaria*, its superlative gravity, that, therefore, *it is not an idiopathic morbid entity*, as has been asserted until now, but the expression of gravity in another morbid state, and that the denomination of yellow fever should be substituted by the one of *grave malaria*, this qualification serving to designate the highest intensity of malaria

II

Amongst the objections that can be made to these doctrines, objections that have already been presented to me, the one that seems most weighty is the following "Yellow fever cannot be of the same nature as malaria, since the first is contagious and the second not"

This is a great mistake In the first place, no one, to my knowledge, has been able to demonstrate the contagiousness of yellow fever, that is, the *transmissibility* of the disease from body to body, by *contact* In the second place, because malaria is susceptible of being transmitted by any individual to persons surrounding him, as well as of being transported to great distances For example An individual is possessed by the helococcus (ελος, swamp, marsh, and *κοκκος*, in Latin *coccus*, *coccum*, a germ, a seed, a small round body This denomination, created by myself to designate the microbe of malaria, is based on the rules established by Egger for the construction of neologisms) He retires to his room, where he remains for several days without appropriate medication The helococcus not being now attacked, and finding in the organism of the patient a favorable field for its development, proceeds on its evolutionary march The patient, whose emunctory apparatus works, discharges continually from his body a certain quantity of these microbes that are thrown into the surrounding air, where, if they meet with favorable conditions, they live, develop and procreate Therefore, after a certain time, the rooms of this individual will be transformed into a genuine focus or nursery of helococci, and, consequently, whoever enters there may receive the same morbific element that is found in a marsh or swamp

And here we have the explanation of the *contagiousness* of "yellow fever," which is at the same time the explanation of the *contagiousness of malaria*, a question that has been despised, why I cannot tell, since it is a known fact, as no one dares to deny, that malaria is a microbiotic disease Thus, a person who has been infected in a marsh, may, in turn, constitute another *marsh*, focus or nursery, as long as his organism affords to the helococcus the necessary conditions for its development and procreation

---

[1] Communicated to the Académie de Sciences of Paris 1885

And if such a case is likely to happen in reference to one single individual, it is much more likely to happen in places where the accumulation of patients is considerable, especially if the *enteric form* of malaria *prevails, if hygienic rules are neglected, or if* the fæcal matters are retained or thrown in the vicinity of these places

Here is another example A ship watering in a place infected by malaria, and carrying to its interior the helococcus, may, *ipso facto*, become a focus of malaria, and of the gravest kind, as its population not only breathes the air impregnated with the deleterious principle, but uses for drinking purposes the liquid drained from the very sources whence it emanates Thence the greater gravity of cases of malaria occurring aboard ships,—cases diagnosticated as yellow fever,—a fact that has led certain physicians to admit, in opposition to all laws of pathology, a "ship yellow fever" and a "land yellow fever," the first being always of a much more serious character than the second

Thus, malaria, though not a contagious disease in the strict sense of the word, is susceptible of being transported to great distances, and transmitted by man, under the condition that the helococcus in the vessel in which it is conveyed meets with the necessary conditions of life, development and procreation

IS TYPHOID FEVER EVER OF SPONTANEOUS ORIGIN?

BY J F JENKINS, M D,

OF TECUMSEH MICH

Whether typhoid fever is or is not of spontaneous origin remains an unsettled question Murchison taught that it is of spontaneous origin Many German writers are of the opposite opinion In country practice we not unfrequently see cases like the following, with a distinct clinical history of typhoid fever

H P, family consisting of wife and four children, living in a rural district, where families are separated by distances of a quarter or half a mile The eldest child, a girl aged 11 years, was attacked with typhoid fever on October 10th, 1884, and was attended throughout her illness by Dr North, of this place The disease assumed a malignant form, and the patient died on the ninth day after taking her bed Three weeks after her death the mother, aged 35, and a son, aged 7 years, were attacked with fever During the first week of their illness they were under the care of a homœopathic physician, but the family becoming dissatisfied, the writer was called to attend them

Both were typical cases of typhoid fever The mother died on the twenty eighth day, the boy made a slow recovery The father, aged 35 years, and a son, aged 9 years, were taken down with the disease Each was attended by a different physician, and both physicians diagnosticated typhoid fever and treated them accordingly

Both father and son recovered There were no cases of typhoid fever within a radius of five miles of this family, but the surroundings were bad The water supply of the family was doubtless contaminated by human excreta This appears to be the only reasonable cause which produced the attack of typhoid fever in this family

There were no other cases in the neighborhood Neither the nurses who cared for them during their illness nor the neighbors who attended at their burial were taken with the disease

Similar examples have come under the writer's observation, where a family living almost completely isolated were taken with fever, whose clinical history proved beyond a doubt the nature of the disease, which in a large proportion of cases is readily diagnosticated from the so called typho-malarial fever The isolated cases so frequently met in country practice are strong proof that typhoid fever originates spontaneously, and that all that is required to produce it is the decomposition of fæcal and other organic matter, which usually contaminates the well from which drinking water is obtained

Tecumseh, November 10, 1885

MEDICAL PROGRESS

MATERIA MEDICA AND THERAPEUTICS

THE ANTITHERMIC PROPERTIES OF THALLIN — PROFESSOR JACCOUD read a paper on this subject at the meeting of the Académie de Medecine, on October 27 His experiments were begun in February, 1885 Of the chemical history of this drug, it is only necessary to say that it belongs to the series of bases of chinoline, that its formula is $C_{10}H_{13}NO$, that its scientific name is tetrahydro parachinanisol, and that Skraup gave it the name thallin on account of its characteristic action in aqueous solutions of thallium The sulphate and tartrate of thallin occur in the form of crystalline white powders The sulphate is soluble in five times its weight of cold water, the tartrate is a little less soluble The urine of persons who have taken thallin has a brown tint, with a more or less pronounced greenish reflection The addition of a few drops of perchloride of iron produces a red color, but there is nothing special in this reaction But if the urine to which the perchloride has been added be treated with chloroform or ether, a characteristic green color is produced

Jaccoud has used thallin in seventeen adult cases, including six cases of typhoid fever, seven cases of pulmonary tuberculosis with pseudo continued fever, three cases of pneumonia, and one case of facial erysipelas The sulphate and tartrate were used indifferently, and the effects are so similar that it is useless to try to make any distinction in a general study

The minimum quantity given in a day was 10 centig, the maximum daily dose 1 gramme In the larger number of cases he gave from 40–50 centig The mode of administration was always the same the drug was given in unleavened bread, and whenever the daily dose was greater than 15 centig, it was divided into two or more equal parts, as desirable. The greatest quantity taken at any one time was 25 centig. These doses were given every half-hour in some cases, but ordinarly every hour. None of the drug was given at any time without a previous thermometric observation. The drug was always commenced at 12 noon, the temperature being taken at that time, and afterwards every hour until 6 P. M. The temperature was always taken in the axilla, and with the same thermometer for all patients.

Effect on the temperature.—The first typhoid fever patient took on the ninth day 75 centig. of the sulphate, and the temperature fell 5.8° Fah. During the eight days following he took 50 centig. each day, with a mean fall of 3.6°. On the two following days he took 45 centig. each day, with a fall of 4.2°, 7.2°, and 4.8°. These were the 18th and 19th days of the disease. In thirty days he took daily doses of from 30 to 50 centig., with one dose of 75 centig., and the mean fall for the thirty days was 4.1°. Another typhoid fever patient took 50 centig. for four days, from the 14th to the 17th day; the minimum fall was 3.9°, and the maximum 5.4°. The mean fall in the cases of typhoid fever was 3.9°, and the average daily drug taken from 10 to 50 centig. In the cases of febrile tuberculosis the effect was scarcely less remarkable. The mean fall of temperature was about 4°, and the daily quantity from 10 to 50 centig.

Rapidity of action.—To properly appreciate this important matter, Jaccoud made a uniform calculation for all cases; the interval of time was measured from the time of administration to the time of lowest temperature. In the twenty seven administrations to six cases of typhoid fever the mean time was one hour and a quarter; for twenty seven administrations in seven cases of tuberculosis the mean time was about three hours. In the cases of pneumonia, the mean time was about one hour and three quarters, and in the case of erysipelas the time was three-quarters of an hour. From these results it seems that the nature of the disease has some effect on the rapidity of the action of the drug, and that it acts more slowly in tuberculosis than in any other disease.

Duration of the effect on the temperature.—Here also the nature of the disease seems to have an effect, and the effect is least lasting in typhoid fever. As regards the persistence of the minimum effect, it must be said that almost as soon as the thermometer has reached the lowest point it begins to rise again. As regards the time necessary for the temperature to rise from the minimum to the point of departure, the mean in typhoid fever was two hours and a half; in tuberculosis three hours and a quarter; in pneumonia three hours; in erysepelis four hours.

The effect on the patient.—When the temperature commences to fall the patient begins to sweat freely, this lasting until the lowest thermometric point has been reached; the perspiration then diminishes, and ceases during re ascension. When the mercury begins to rise the patient, covered with perspiration, complains of a sensation of coldness, and in some cases there is a slight short chill. These effect are less marked than when antipyrin is used. In none of his cases did Jaccoud observe any gastric or cephalic effects, nor were there any phenomena relating to the organs of sense. It may be said, then, that the accessory effects may be said to be *nil*, on account of its energetic action, however, the medicine should be given with caution: collapse may be easily induced, even with moderate doses in cases of individual idiosyncrasy. It is the part of prudence, therefore, not to exceed a quantity of 20 or 30 centig. on the first day; and when the patient is much debilitated the quantity should not exceed 10 or 15 centig. As is the case with many drugs, thallin sometimes produces an exanthem, exactly similar to that caused by antipyrine: small spots of papular exanthem, isolated and of small size at first, after which they extend, unite and become confluent; when the eruption is of a fiery red color; it disappears on pressure, and returns immediately when the pressure is removed. It usually begins in the region of the knees, preferably on the internal surface, and looks as though it might be the effect of pressure of the limbs together. When it extends it has the remarkable and characteristic property of extending only on the extensor surfaces. As yet it has not been seen on the face. It is accompanied by a sensation of itching and burning. It usually lasts for about three days, though it may last five. It disappears without desquamation, as a rule. (This, it should be remembered, is the characteristic eruption of both antipyrin and thallin.)

Effects on the disease itself.—As is the case with antipyrin, thallin has absolutely no effects on the symptoms or evolution of the disease except the temperature; and even here it does not affect the general temperature curve. Here again it is somewhat similar to antipyrine.

As regards antipyrin and thallin, then, it must be concluded that these agents are not a real addition to medical therapeutics.—*Bulletin de l'Academie de Medecine*, No. 43, 1885.

[In a communication presented to the Academie on the following week, M. DUJARDIN-BEAUMETZ takes issue with Jaccoud as to the value of antipyrin and thallin. He denies the superiority of thallin over antipyrin, and asserts the couverse for the following reasons: It is less active, and therefore more manageable; its depressing effects are less marked: and because thallin acts on the blood, and lowers the temperature by diminishing the respiratory power of the blood (in which it resembles kairin). Antipyrin, however, (and like it, salicylic acid, quinine and resorcin) lower temperature by acting probably on the thermogenic centres of the spinal cord. Kairin and thallin are not antiferments (as antipyrin, resorcin, etc.), but act directly on the blood globules, as has been shown by Brouardel, Loye, Hénoque, and Huchard. They may, therefore, be dangerous in the infectious diseases, in which the blood is already altered, and should be used only with great caution. Dujardin-Beaumetz admits that antipyrin has no direct influence on the course of the disease; that it is not well borne by some patients; and that the sweats caused by it enfeeble the patient. It is nevertheless true that its effects on tuberculous patients are excellent, and much more frequently good than bad. In the fever of resorption *(fievre de resorption)* antipyrin is superior to quinine and salicylic acid. We cannot expect to cure consumption by it, but we can successfully combat the pyrexia or hyperpyrexia, and for this purpose alone antipyrin is least objectionable. He believes, therefore, that antipyrin is a positive addition to therapeutics.—*Bulletin de l'Academie*, No. 44, 1785.

In Guttmann's opinion antipyrin is far superior to thallin or kairin, and entirely free from objectionable concomitant symptoms. Landenberger, Livierato and Predazzi, on the other hand, consider thallin as the best pure antipyretic, and assert that *it* is free from concomitant symptoms. Landenberger has used it in croupous pneumonia, typhoid fever, peritonitis, pleurisy, tuberculosis, erysipelas of the face, miliary tubercle, acute rheumatism, puerperal fever and gastric fever sixty-nine cases in all. He administered it in single doses of gr. iv (25 centig.), gr. viii, and gr. xvi. The pulse fell in the same ratio after large and small doses, but the respiration was not materially influenced. Livierato and Predazzi used thallin in pneumonia, intermittent fever, pleurisy, diphtheria, and other febrile diseases, with success.]

DEODORIZED IODOFORM.—Many attempts have been made to overcome an almost fatal characteristic of iodoform—its disagreeable smell—without destroying the antiseptic virtues which it possesses. Surgeon-Major OPPLER, of Strassbourg, has just communicated to the *Centralblatt fur Chirurgie* the results of some experiments in this sense, which seem to have solved the problem. He takes finely ground coffee and mixes it with the iodoform in varying proportions, 30 per cent of the coffee almost neutralizes the odor, while 40 to 50 per cent completely destroys it. Mixed with iodoform ointment (1–10) in the same proportion, coffee quite deodorizes it. A point of great importance is that coffee itself possesses great antiseptic power, and exerts no deleterious effects on the wounds. Thus a smaller quantity of iodoform suffices, the disagreeable odor is abolished, and the occasional evil effects are done away with. Coffee has the power not only to arrest decomposition, but also to postpone it. Professor Lucke is of opinion that coffee-iodoform may answer well enough for outward applications, but that it is unsuited for the interior of wounds, as the coffee would be a foreign body and interfere with healing. The coffee, previously roasted, of course, must be ground into a very fine powder before the iodoform is added, and the two must then be intimately mixed. Time alone can decide whether this combination will secure a much desired end, or whether, like peppermint oil, tonquin beans, tannin, Peruvian balsam, and other substances which have from time to time been tried, the iodoform will prove itself the stronger.—*Medical News*, August 29, 1885.

SURGERY

IMPROVEMENTS IN EXCISION OF THE KNEE-JOINT, AND IN THE LIGATURE OF LARGE ARTERIES.—MR. EDWARD THOMPSON says, on this subject: There are some points in the treatment of excision of the knee-joint, both at the time of operation and subsequently, which seem to me to deserve particular attention. I have had a good many of these cases under treatment from time to time in the Tyrone Infirmary, and the suggestions I have now to make, and which I desire shortly to detail, are the outcome of my experience.

In the first place, I always make the first incision nearly straight across the limb, and as small in extent as possible, with one sweep of the knife the ligamentum patellæ is cut through, and the joint opened. The upper end of the ligament is then seized and dissected off the bone, and the patella removed. The subsequent steps of the operation require no comment. When the bleeding has ceased, the cut surfaces of bone are placed in close apposition, and the divided ends of the ligamentum patellæ are strongly stitched together with carbolised silk, the skin-flaps are brought together in the usual manner, and the wound closed no drainage tube being inserted. The limb is at once put up in plaster of-Paris, with a back splint of strong hoop iron, another strong piece of iron is bent over the situation of the wound, so as to allow the application of the proper dressings, two side-splints of hoop iron, about eighteen inches long, and slightly hollowed over the wound are placed lengthways, across the site of the joint, and over the plaster of-Paris, the whole being firmly secured by a bandage. A completely rigid and comfortable bed is thus secured for the injured limb. The upper and lower portions of the limb are padded with French wadding, and, close to the wound, with carbolic tow. If there be any discharge from the wound it will penetrate the tow, which can be readily removed and replaced without disturbing the limb. I have heard a great many discussions, and read a great many elaborate articles, on the proper method of treating these cases, but, as yet, I have seen no apparatus which is so easy of application or so reliable as the plaster case I have attempted to describe, and which is coming into very general use.

The chief points I wish to emphasise are—1. the small extent of the primary wound really necessary, 2, the preservation of the ligamentum patellæ, not by its non division, but by the divided ends being stitched together, 3, the enormous anterior support afforded by the preservation of the ligament, and the lessened tendency to displacement, 4, the increased power given to the limb by preserving almost intact the insertion of the powerful crureal muscle, 5, that stitching the patellar ligament seems quite as efficacious as the recommendation by some authors of its non division, and that, while effecting subsequently the same purpose, it in no way hinders, or renders more difficult, excision of the joint.

In all my recent cases of amputation of the thigh, I have tied the femoral artery with a strong carbolised silk ligature, and cut off both ends short. The wound has healed, and remained healed, in every case. Thus a troublesome cause of irritation—one end of the ligature being left hanging from the flap—and a very great impediment to the healing of the flap-wound by first intention, has been effectually got rid of.—*British Medical Journal*, Nov. 7, 1885.

JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION,
No 65 RANDOLPH STREET
CHICAGO ILLINOIS

SATURDAY, DECEMBER 5, 1885

THE RELATIONS, PAST AND PRESENT, OF THE AMERICAN MEDICAL ASSOCIATION TO THE NINTH INTERNATIONAL MEDICAL CONGRESS

From the erroneous statements that continue to be made in certain portions of the medical press of our own country, and still more in some of the medical periodicals and by distinguished individuals of other countries, it would appear almost a hopeless task to correct such statements, or to get the sources from which they emanate to comprehend and acknowledge a few simple but important historical facts

For instance, Prof Virchow is represented as recently saying that "the American Medical Association, a vast society of practising physicians, extending throughout the land, *usurps* the control of the organization of the next session of the Congress, and creates such confusion that I am informed, *verbally* and *by letter*, that no one at present is able to see his way out of the difficulty" The *Berliner Klinische Wochenschrift* speaks of "sitting under the *presidency* of Dr Shoemaker" The *Medical Times*, of London, after quoting the *Wochenschrift's* transformation of Dr Shoemaker from a simple Secretary of a Committee of Arrangements into the President of the Congress, exclaims in apparent apprehension "Suppose Dr Shoemaker and his friends decide that the Congress of 1890 shall be held in Texas!" The editors of a few of the medical journals in this country exhibit but little less confusion of ideas regarding everything that has been done, either by the American Medical Association or its Committee of Arrangements They persistently confound the Committee of Arrangements and its Chairman and Secretary with the officers of the Congress, and some of them even now regard the present organized Executive Committee of the Congress as a "sub committee of the Committee of Arrangements"

The *Medical Record*, of New York, in its leading editorial for November 21, 1885, after its customary misrepresentations about "New Code" and "medico-political issues," neither of which have anything more to do with the present Rules adopted for the Preliminary Organization of the International Congress, than they have with the war between the Kings of Servia and Bulgaria, says "A few weeks ago the Executive Committee of the Congress passed a resolution declaring their independence of the American Medical Association, and thus entirely cutting themselves away from the authority of that body" Again it says "As matters stand at present, the management of the next Congress is in the hands of an Executive Committee representing the new and enlarged Committee, the best men of the country have withdrawn from all connection with the Congress, and the great majority of the numerous important vacancies in the list of officers remains unfilled" And it concludes with the following extraordinarily *patriotic expression* of sentiment "As there seems to be distrust of the Congress abroad and absolute hostility to it at home, the question is asked if it would not be wiser to have no Congress at all? Under the present policy this seems to be *very advisable*"

Here is exhibited a singular idea of the obligations incurred by the profession in the United States when the invitation extended in its name was formally accepted by the last Congress in Copenhagen in open session, and it became impliedly pledged to make every needed arrangement for the meeting it had invited The maintenance of simple good faith in the performance of duties voluntarily assumed on the part of the profession of our country, to say nothing of its honor and scientific interests, appears of very little importance in the estimation of the *Medical Record* Because there have been sufficient differences and misunderstandings, fostered actively by the *Record* itself, to create *distrust* abroad, and some direct hostility, largely again from the *Record* itself, at home, the profession of this country should ignominiously forfeit its obligations to the profession of the world and let the International Medical Congress, it had invited to assemble in our National Capital, die Yes, rather than lay aside personal prejudices and individual preferences, and come together under Rules confessedly unexceptionable, and a Preliminary Organization capable of accommodating fairly all desirable interests, the *Medical Record* says "to have no Congress at all seems to be very advisable"

We are glad to know that such sentiments are shared by only a very few members of our profession, and that there are gratifying indications of returning harmony, sufficient, at least, to maintain the honor and integrity of the profession, and make the Congress of 1887 equal to any that have preceded it, even though the *Record* should continue its unpatriotic misrepresentations to the end But how much better would it be for all parties, if now, when the Committee of Arrangements has transferred the whole future management of the Congress to the Executive Committee of the Congress itself under the most liberal Rules, all parties should lay aside their personal preferences, at least so far as necessary to restore that cordial cooperation which would speedily remove the *distrust* abroad, and render *hostility* futile at home The Executive Committee have formally invited this cooperation, and are delaying the filling of the only three important vacancies that remain at the heads of Sections to learn the results of their overture

THE CONTAGIOUSNESS OF LEPROSY

At the meeting of the Académie de Médecine, of Paris, on July 28, M Constantin Paul read a report on a study of the lepers of Constantinople, by Dr Zambaco In this report he attempts to show that leprosy is not contagious, he does not admit that a healthy person can contract the disease from a leper, even by inoculation, and this conclusion has been reached after a thorough study of the disease in Norway, Egypt and Constantinople And while he cannot admit the influence of contagion, he thoroughly endorses the views as to the hereditary origin of the disease,—views which are supported by the investigations of Boeck and Danielssen, and also by a study of the disease as it occurs in restricted localities, such as in Louisiana and New Brunswick, where it may be traced back in families for several generations, as in Norway

At the meeting of the Academie on October 13, M E Vidal read a paper on "The Contagiousness of Leprosy," which was substantially an answer to the communication of M Zambaco As to heredity being the sole factor in the propagation of leprosy, he thinks it sufficient to say that the children of lepers often remain free from the disease, that even when these children are attacked the disease seldom makes its appearance before the eighth year, and that it may skip one or two generations entirely Since Zambaco is an advocate of the theory of heredity, he has made the most careful investigations on this point in the East, but he has been able to find that in only one fortieth of the lepers is the disease directly or indirectly hereditary Even in those places which afford the strongest proofs of heredity it often fails to appear in the descendants of lepers, and often affects persons in whose families it has not previously existed, and it is a well recognized fact that it sometimes affects persons, in countries where it is not at all prevalent, who have visited places in which it is endemic, and that immigrants to infected from non infected districts are often attacked (White)

In order to explain how so small a proportion of the cases in the East are traceable to hereditary transmission, Zambaco thinks that the disease, necessarily of external origin, is *acquired*, the preponderating influence being attributed to want, eating salt fish of inferior quality, and in some cases to violent moral emotions The theory of transmission by inoculation, however, is strongly supported by some of the examples cited by Zambaco He says "Lymphatism and scrofulism predispose to leprosy I have often seen persons who had for several years had scrofulides or common affections of the skin (eczema, psoriasis, prurigo, acne rosacea, itch, etc) later become leprous, and sometimes preserve the old cutaneous affection along with the leprosy" But are not these persons, asks Vidal, debilitated by want and disease, living promiscuously with lepers, in the most favorable conditions for contracting leprosy? In contact with the blood and pus from the ulcers of those already affected, is not the skin, which is already excoriated and open to inoculation, in a fit condition for infection? It need scarcely be said that those who have studied the disease as it exists in the Hawaiian Islands, firmly believe that it is contagious in the sense of being transmitted from one person to another by inoculation, as may be seen by reference to the writings of Kneeland White, and Tryon The physicians in the islands of Reunion and Mauritius believe in the contagion of leprosy Le Juge de Segrais writes that there are several thousand lepers in Mauritius, and that all the physicians on the island believe that the disease is essentially contagious "There is no doubt of it It is also hereditary, attacking families in good circumstances, in which want has never existed"

The first methods of segregation of lepers, says Vidal, arose from the ideas as to its contagiousness, and facts show conclusively that this is by far the best method of dealing with the disease, so far as preventing its spread is concerned As regards the question of contagion, however, he thinks that leprosy is contagious only by inoculation Without admitting the possibility of this mode of transmission it is impossible to explain very many cases of leprosy Doubtless such inoculation is often difficult, and a long time must sometimes elapse before the effects are seen On the other hand the effects sometimes appear very quickly Vidal cites the case of a woman who became leprous soon after her husband contracted the disease, there being no history of leprosy in her family, and she had never been outside of France The husband contracted the disease at Nice, where there were a number of lepers Similar cases have been reported by other writers, the most recent by Poupinel

---

In connection with this subject may be mentioned the recent report of Brigade Surgeon H V Carter, of the Indian Medical Service, British Army, on the prevention of leprosy by segregation, quoted in the *British Medical Journal*, of Nov 14, After reviewing the status of the disease in Norway, and the death rate, and the influences that may have tended to lesson the prevalence of leprosy he concludes that "the amendment of public health cannot be satisfactorily accounted for by reference solely to a general improvement in diet, dwellings, soil, or climate, nor has purely medical treatment ever proved curative, and so far from leprosy, in Norway showing a natural tendency to subside, there is ample evidence of a present activity equal to that displayed by the disease twenty-five years ago " He thinks that there are three practical methods of segregation, which may be separate or combined (1) The erection of plain asylums at certain centres, each to be a refuge common to several districts, and a place of detention, under proper management and supervision (2) The foundation of leper colonies or village communities of the affected, who, while allowed more liberty of movement, should not be allowed to mingle with the peasantry around, which would need strict supervision, (3) Requiring the strict isolation of lepers who are retained in their own homes at the request of their friends, for which suitable separate lodgings are indispensable

As regards the statement "nor has purely medical treatment ever proved curative," it should be remembered that Unna has reported a case of lepra tuberosa cured in four months (see THE JOURNAL, October 31, 1885, p 486) Such a report coming from so careful an observer admits of no reasonable doubt, and is worthy of great attention by those who have the care of lepers

CREOSOTE IN THE TREATMENT OF CONSUMPTION

The history of creosote exemplifies the mutations to which therapeutics are liable, particularly as regards phthisis Furthermore, the change of professional opinion from time to time, and the contradictory statements of physicians concerning the value of remedies in tuberculosis only illustrate the powerlessness and desperation felt by medical art when opposed by so dreaded a foe

After the discovery of creosote by Feichenbach, in 1830, and before its therapeutic range became limited by practical experience, it was recommended for almost every form of internal and external disease One of its many uses, suggested perhaps, by the fact of its derivation from wood-tar, was in the treatment of pulmonary complaints, and in consumption it soon won great distinction After a time, however, the remedy fell into discredit in the treatment of phthisis, except in the form of an atomised solution for inhalation Used in this way it long retained considerable popularity, particularly when the sputa were fetid Although its internal administration was abandoned in consumption, it was not altogether dropped from the list of agents available for chronic bronchitis, while on account of its hæmostatic properties it was occasionally administered in pulmonary hæmorrhage Nevetheless the internal use of creosote was exceptional, and the mass of the profession employs it only in inhalation

It is with all the greater interest, then, that we find Jaccoud reverting to one of its discarded uses, and recommending it strongly as one of the indispensable internal remedies in the therapeutic management of consumption In his recent work, to which reference has been made repeatedly in the editorial columns of THE JOURNAL, he dwells at some length upon the therapeutic indications furnished by the general malnutrition of tuberculous patients These indications are met by hygienic measures, and the administration in large amounts of cod liver oil, glycerine, iron, arsenious acid, etc But there remains a second indication, which is to counteract the irritation and other local effects of the lesion Formerly Jaccoud met this indication, he states, by the administration of balsams, tar, or turpentine, but since the investigations of his eminent colleagues Bouchard and Gimbert with beechwood creosote he has substituted this agent for the others just mentioned He is of the opinion that it acts more rapidly and surely in lessening expectoration and ameliorating the bronchial lesions, and thus tends to limit the extension of the local changes "Nor is this all, since creosote seems also to have some effect on the fundamental lesions themselves, and to promote the sclerotic change by means of which recovery is found to occur in this disease."

He has often observed that after the physical signs have shown the pulmonary disease as diminished in extent, and the "peritubercular catarrh" lessened, the administration of the drug for several months longer has resulted in a still further decrease in the area of the local changes. This limitation of the disease he ascribes to sclerosis of the peripheral tissues. "On account, then, of these and other analogous facts, creosote, combined with other means of treatment, seems to act not only upon the catarrhal but also upon the tuberculous lesions, causing the sclerotic change to predominate over that due to sloughing or caseation." It should be said that, in addition to vigorous measures directed to the improvement of the constitutional condition, he employs alcohol, with strong and declared faith in the power of this last named agent to promote the sclerotic change. "Independently of these results, creosote may be also recognized to have an antiseptic or anti putrid effect, on which account the fever due to absorption (*la fievre de resorption*) is averted for a considerable time." Creosote is, in his estimation, so valuable as to be an indispensable remedy, and he never omits to employ it. Although not immediate, its effects are permanent and decided, even when given in small doses. Pyrexia is no contraindication to its employment. Indeed, the only limitation to its use is the gastralgia which it provokes if the stomach be irritable, or the dose too large. In order to avoid this complication, the dose should be small, in which case the remedy can be taken for months with benefit.

If intolerance once occurs, it is most difficult to again administer the drug. "It should therefore be the rule to administer a small dose at first, and to increase it but gradually, beginning with the amount of not more than 3 minims daily, which may be increased by 1 minim in each week or ten days until as much as 5 or even 6 minims are given. This dose should never be exceeded, and is but rarely reached." Jaccoud no longer administers creosote in capsules, because of the gastric irritation produced, nor does he give it in wine, owing to the disagreeable taste of the mixture. He combines it with the cod-liver oil or glycerine, as follows: Cod-liver oil, 2 ounces; creosote, 3 minims; and oil of peppermint, 1 minim. This constitutes the daily dose, and, owing to the peppermint, is not disagreeable to take. If glycerine be employed, the formula is: Glycerine, 12 drachms; cognac or rum, 3 drachms; creosote, 3 to 6 minims; and essence of peppermint, 1 minim. This combination is highly agreeable and beneficial, and can be taken, according to Jaccoud, for an indefinite length of time.

Although one may not be inclined to endorse or accept all of Jaccoud's conclusions concerning this remedy, yet the experience of so skilful a clinician should not be allowed to go for naught. It is not unreasonable to assume, therefore, that, if employed systematically and persistently in the treatment of consumption, creosote will yield better results than is generally believed, and that the praise lavished upon it in years gone by was not wholly unmerited.

HYPNONE—THE NEW HYPNOTIC

Phenyl methyl-acetone or aceto phenone are the chemical names of a new drug, upon the hypnotic properties of which M. DUJARDIN-BEAUMETZ has recently made a report to the Académie de Médecine, and which he has thoroughly studied with Dr. Bardet, at the Hôpital Cochin. On account of its very marked hypnotic properties the experimenters propose for it the name hypnone, which is more convenient than the other names, and is at the same time descriptive of its properties and nature. It was discovered by Friedel in 1857; its formula is C_8H_8O; it is a liquid at 20° C., and boils between 198° and 199° C. Its specific gravity is from 1,032 to 1,015; it is not soluble in water, and its strong odor resembles that of cherry-laurel water or cut oats. Its physiological properties have been studied by Popoff and Nencki, who showed that it is transformed in the organism into carbonic and benzoic acids, and that it is finally found in the urine in the hippurate state.

When administered to an adult in doses of 3 or 4 drops—5 to 15 centig.—mixed with a little glycerine and given in a gelatin capsule, hypnone produces deep sleep, and in alcoholic subjects its hypnotic properties are superior to those of chloral and paraldehyde. Dujardin-Beaumetz and Bardet have administered it to nine patients, and have as yet seen no symptoms of intolerance. The halitus becomes unpleasant from the elimination of acetone by the lungs. Injected under the skin of a guinea-pig 50 centig. caused profound sleep, which deepened into coma, in which the animal died in about six hours. The discovery of a drug with such effects from a very small dose must be regarded as a valuable addition to therapeutics. It still remains to see why it is a hypnotic, and whether further experimentation will abundantly confirm the claims of the distinguished clinician who now reports upon it.

SOCIETY PROCEEDINGS

OBSTETRICAL SOCIETY OF PHILADELPHIA

Stated Meeting, Thursday, November 5th, 1885

THE PRESIDENT, B F BAER, M D, IN THE CHAIR

(Concluded from page 612)

Dr William Goodell exhibited the ovaries from

TWO CASES OF OOPHORECTOMY FOR OVARALGIA,

with the following histories When the patient, an unmarried woman, aged 30, first consulted him, she weighed 236 lbs , but at the same time she was very weak and could barely walk She suffered excessive pain at her catamenial periods, which appeared only at long intervals She had cataleptic and hystero epileptic fits, and complained of very constant and acute ovarian pains Her urine was passed but once a day, and this act was attended with much suffering The womb was enlarged and the ovaries were very tender indeed, but nothing else abnormal was discovered Asafœtida and the bromides were prescribed in large doses, and she was advised to try the rest treatment Fourteen months later, she was again brought by her physician to consult Dr Goodell She now weighed only 120 pounds, having lost 116 pounds, and she was in every respect worse, her ovarian pains being now constant and very acute, requiring large doses of morphia to control them Her catamenia had not appeared for nearly four months, and tonics seemed to have no effect whatever on her Her physician was compelled to be in constant attendance on her, and was liable to be summoned at any hour of the day or night to give her a hypodermic injection Masturbation was suspected, but she always denied practicing this habit Nothing further could be done than the operation of oophorectomy, which was accordingly performed a few days later at the hospital of the University The ovaries were found much enlarged from cystic and interstitial degeneration, but there were no evidences of peritonitis or of cellulitis, which had been suspected A corpus luteum existed in one ovary, a rectal hæmorrhage or vicarious menstruation having taken place a few days before the operation Her ovarian pains at once left her, she needed but very few doses of opium, which was given by rectal suppositories Her convalescence was prompt, and she returned home in less than four weeks free from all pain, and in a fair way to get perfectly well The case was a typical one of the advantages of oophorectomy, nevertheless he thought that the operation was being performed altogether too frequently

OOPHORECTOMY FOR BLEEDING FIBROID OF THE WOMB

In this case the lady was 37 years of age, and had been married eleven years She gave birth to a child about seven years ago, and since then has had one premature birth at seven months and one miscarriage She first noticed an abdominal tumor nine years ago, but her catamenia began to be free some time before this Late in the year 1881 the catamenia began to be excessive As nothing served to check them, early in the following year Dr Goodell was consulted He found multiple fibroid of the womb Six tumors could be readily made out, of which two seemed pedunculated, the sound gave a measurement of 4 5 inches Under ergot and ammonium chloride the patient improved for several months, then the menorrhagia became worse, and finally a dribbling of blood kept up between the periods In May of the present year, she again consulted Dr Goodell She had been dribbling continuously from January, and was much reduced in strength Being a brunette, she exhibited the *facies uterina* in a most marked degree, the pigmentation being very dark and extensive The womb now measured 7 5 inches She was admitted into Dr Goodell's private hospital, and on May 24 both ovaries were, without difficulty, removed They were greatly enlarged by follicular degeneration, a condition which Dr Goodell had repeatedly seen in cases of fibroid tumor The effect of the operation on the tumors, and especially on the main one, was astonishing After two weeks this fibroid had diminished in length nearly a hand's breadth Her recovery was prompt, and she was sent to Atlantic City to recruit On July 10, just forty-seven day days after the operation, she called on Dr Goodell, who found the tumor very greatly reduced in size and the uterine cavity measuring only 3 25 inches, a diminution of 4 25 inches This extraordinary amount of diminution, in spite of the fact that the obliteration of the ovarian blood vessels cut off only a small portion of the blood supply to the womb, drove him to the conclusion that the ovaries were the important factors in inviting blood to the womb Every successful case in which he had removed the ovaries for fibroid tumor of the womb had been followed by the menopause and by rapid diminution in the size of the tumor But in his hands, and in those of others, this operation was more fatal than that of ovariotomy During the ten months of the present year he had had twenty-five cases of ovariotomy with but one death, and that one in a lady operated on at her home, 200 miles from Philadelphia For simple cases of oophorectomy the mortality should not be greater than that of ovariotomy, but, when complicated with the presence of a large or an adherent fibroid tumor, the operation is often one of great difficulty Twice during the past year he was unable to reach the ovaries, and was compelled to abandon the operation because, in neither case, was the woman willing to undergo the risk of having hysterectomy performed Each case recovered, and while the women were under observation the tumors appreciably lessened in size, as if the shock of the exploratory incision had temporarily suspended the ovarian influence

Dr E E Montgomery was glad to hear the good results in Dr Goodell's cases In a few of the cases upon which he had operated, the menopause did not at once occur, sometimes not for two years after the operation In such cases the tumor did not decrease in size while menstruation continued In the case of hysterectomy for fibroid tumors reported by Dr Montgomery at the last meeting, the temperature at no time exceeded $101\frac{3}{5}$°, and the patient left the hospital to day, perfectly well He preferred removal of the uterus and its appendages entire when the ovaries cannot be removed in consequence of previous inflammatory changes Ligation of blood-vessels supplying the tumor might be useful when nothing better could be done

Dr Baer thinks that when the ovaries can be removed, it is the preferable operation

Dr Goodell has been so uniformly successful in removing the ovaries for the cure of fibroid uterine tumors, that it is his choice He has been notified that in a case of fibroid tumor of the womb in a woman aged 33 years, he will be called in consultation, this will be the third He will advise removal of the ovaries, if at the time of operation that is not found possible, he will close the incision, as the other operation is very dangerous, and the patient can certainly live a few years as she is In one case only of his oophorectomies have the menses continued, and he thinks that in that case there must have been some supplementary ovarian tissue

Dr E E Montgomery exhibited for **Dr W H Warder**

A LARGE OVARIAN TUMOR,

and related the following history The patient was a young woman Her menses commenced at 17 years of age and had always been irregular They ceased entirely for twelve months, and at the same time the abdomen was enlarging until the tumor reached above the navel Fluctuation was doubtful, the mass seemed quite solid, and pressed the uterus down into the pelvis Anæsthesia did not relax the abdominal wall, and diagnosis was doubtful An exploratory incision, showing the pearly tint of an ovarian tumor, made it sure Nothing would pass through the trocar, but some of the jelly like contents of the tumor escaped beside it and passed into the abdomen The large cyst was filled with small cysts The patient did well for one week, then the pulse became rapid, but she has since been doing well and is now rapidly recovering

Dr Goodell thinks the danger from the escape into the abdomen of cyst contents is overrated

Dr Baer said that in the early stage of ovarian tumors metrorrhagia is sometimes present, sometimes the menses are entirely absent He should like to hear from the Society some reason for this inexplicable difference

Dr Goodell has observed the same fact, but can throw no light upon it

Dr Montgomery remarked that in this case both ovaries had undergone cystic degeneration The second ovary contained numerous small cysts In reply to Dr Baer's inquiry about the treatment of the second ovary, Dr Montgomery said that it was removed

Dr Chas Herman Thomas read a paper on

SOME USES OF COCAINE IN GYNÆCOLOGY

Seldom does a new drug reach so sure a place in the confidence of the medical profession as that accorded to cocaine I early began its employment in ophthalmic practice, and soon extended its use to a variety of gynæcological applications The results obtained have been so satisfactory that I now never go to such a case without cocaine in my bag or pocket After considerable experience in its use, I am convinced that it is quite as valuable in the latter case as in the condition for which it was originally recommended That it is a local anæsthetic when applied to mucous surfaces is a familiar fact, but its property of reducing in inflammation and engorgement of the same class of tissues is not so generally recognized, notwithstanding that is a point of considerable practical importance This action of the drug is readily verified by observing the marked paleness and shrinkage which follows in a few moments after its application to surfaces thus affected While this condensation of tissue is to a considerable degree temporary, it seems to be of longer duration than the accompanying anæsthesia In some cases the good results obtained by reducing hyperæmia in this manner appear to be permanent The common fear that it will fail to prevent pain may usually be overcome by placing a few drops of the solution on the tip of the patients tongue, when the numbness produced seldom fails to induce full confidence in its efficacy

Cocaine hydrochlorate is the salt upon which my experience is based[1] A four per cent solution, gr ijss to f℥j of water, acts well for most purposes, though a somewhat weaker or stronger one may sometimes be substituted with advantage The addition of boracic acid in the proportion of gr ij to the f℥j insure sterility of the solution When used, it should be applied with thoroughness, the parts being first freed from mucus and some minutes allowed to elapse for its effects to develop, the time should be *not less than ten minutes*, and in cases where considerable pain is to be anticipated, a strong solution, ten per cent or more, may be employed, and the application repeated after an interval of ten minutes, and in five minutes from the beginning the full effects of the drug may be looked for That the anæsthesia produced by cocaine is complete, I have personally experienced, having made use of a four per cent solution by injection into the nostrils previous to an application of the galvanic cautery to the nasal cavity The cautery had been applied at a previous occasion without cocaine and the pain was severe With it, not the slightest pain was felt, and I was conscious of the action of the cautery only by the hissing sound produced

I have found it particularly valuable in certain cases of cervical endometritis in which, though there may be no erosion externally, and but little characteristic discharge, there is a state of extreme sensitiveness existing about the region of the internal os uteri, a probe or cotton, easily bringing blood, and any application made to the part is liable to produce bleeding and severe radiating and ovarian pain Cocaine carefully applied with the syringe or the cotton-carrier, prevents the pain and bleeding, which would otherwise follow the necessary medicinal application, the swelling being also materially reduced The congestive or inflammatory stenosis which usually exists is consequently for the time relieved, and applications to the part itself, as well as to the entire endometrium, are greatly facilitated In urethral caruncle sensibility may be so destroyed that the painful excrescences may be clipped off and the site painlessly cauterized Cocaine is also extremely useful in painful irritation and inflammation of the female urethral tract, and especially of the part just within the meatus, a condition attended with distress frequently referred to the bladder Appropriate medication is painlessly made after its application, which may be conveniently made by means of the glass medicine dropper, as a means of preparation for the operation of stretching either the urethra or the cervix uteri it is of unquestionable value To precede the application of caustic to a chancre it is also effective I am informed by my friend, Dr Levis, who has had a large experience with the drug, and who uses it extensively and with great satisfaction, that plastic operations upon the vagina where considerable surfaces are to be flayed, the cocaine anæsthesia is insufficient to prevent pain It has been recommended in dysmenorhœa, and there is good reason to believe from several reports which have been made, that it is capable of producing excellent results when applied to the os uteri and to the cervical cavity by means of a small cotton tampon I tested it recently in a case of uterine colic, using it hypodermically in two doses of one grain each about half an-hour apart, but without appreciable relief It has been tried internally in doses of one grain or more in the vomiting of pregnancy, and has met with some favor, but in the only case within my own knowledge it entirely failed

---

[1] The price has been reduced to ten cents a grain or less

In a case of vaginismus brought me by a practitioner from a neighboring city, the condition was quickly relieved by the local application of cocaine, and a complete examination was easily made, when without its use general anæsthesia would have been necessary In a case of hyperæsthesia of the vagina with mild vaginismus, in which frequent local treatment was required, a suppository containing one grain of cocaine introduced into the vagina a half hour before each treatment, entirely abolished the spasm and rendered the introduction of the speculum easy and comparatively painless Cocaine suppositories also produced excellent results in a case of rectal tenesmus after opium had proved insufficient Cocaine has been recommended in operations for lacerated cervix, and for the crushing of stone in the bladder I have not made use of it in either of these applications, but strongly believe in its value In one hyperæsthetic patient in whom violent pain was developed on slight provocation, and who required local treatment of the cervix uteri and urethra, but who suffered so much from ordinary applications that the local benefit was fully counterbalanced by harm done nervously, it became necessary to suspend treatment on this account After cessation for six months, treatment was resumed under cocaine, and it has since been in every way satisfactory, the pain formerly produced by applications to the cervix being now entirely absent In the same patient painful irritability with spasm of the bladder simulating cystitis, which was not entirely relieved by the opium suppository and other measures, yielded completely, and thus far permanently, to a single injection of one grain of cocaine thrown into the bladder The resumption of treatment in this instance was largely due to the enthusiastic approval of the husband, who had himself experienced complete relief from the injection of a dram of the two per cent solution into the deep urethra for a violent urethrismus In another instance, in a woman with irritable piles, red as a ripe strawberry, and who was suffering extreme discomfort, the piles shrank and turned pale under the cocaine application, and were then painted with tincture of iodine with entire absence of pain

Dr Keating has used cocaine for some time in the same class of cases He now uses eight per cent solutions with great success, especially in children's throats He employs salicylate of cocaine in diphtheria in a five or six per cent solution, sensibility disappears in a short time, and he can then use any application without discomfort He applies carbolic acid, tincture of iodine, etc , in this manner without exciting pain He also applies cocaine before injecting carbolic acid into piles, and also applies it on cotton to prevent its action ceasing too soon

Dr Thomas said that the strength of the solution may, with propriety, be greatly varied, and that in his practice upon the eyes, even a one per cent solution was strong enough to be of considerable value in conditions of irritation produced by foreign bodies in the eye, but in other cases, as urethral caruncle, it might be well to use it even in saturated solution The question of strength is largely a question of expense, for in local application no toxic results are likely to be produced

MEDICAL SOCIETY OF THE DISTRICT OF COLUMBIA

Stated Meeting, October 21, 1885

The President, W W Johnston, M D ,
in the Chair

Dr J B Hamilton presented for the inspection of the Society the patient upon whom he had performed a

LAPAROTOMY FOR A PISTOL SHOT WOUND OF THE ABDOMEN PIERCING THE INTESTINES,

whose case had recently been fully reported in the Journal of the American Medical Association (See page 202)

Dr G N Acker presented

A PSAMMOMA OF THE FOURTH VENTRICLE,

together with the cerebellum and pons The tumor arose from the vessels of the fourth ventricle, and filled the ventricle The arteries of the cerebellum were in a state of calcareous infiltration The man suffered from some vomiting spells, vertigo and convulsions The seizures would come on suddenly and last for some days A brain tumor was suspected

Dr S S Adams read a paper on

ANTIPYRIN, ITS HISTORY, PHYSIOLOGICAL ACTION, AND THERAPEUTIC EFFECTS

(See page 621)

Dr King thought the reduction of temperature in the dog was due to an almost fatal condition of collapse

Dr Louis Kolipinski explained thoroughly the various steps he had taken in discovering the physiological action of antipyrin upon the dog

Dr C E Hagner said he did not propose to discuss antipyrin, for he had had no experience with it He thought, however, that it was a great mistake to be constantly endeavoring to reduce temperature Every disease has a natural course, and within certain limits fever is a part of that course If the patient's system is able to stand the waste, the fever may safely be permitted to run its definite course At any rate, more harm is done by using antipyretics which affect the heart secondarily He believed that many times salicylate of soda and similar drugs rather hasten death than otherwise The same fault, it was true, could not be found with quinine, and for that reason he preferred it as an antipyretic In some diseases it was best to have a high temperature, but when it got too high, he gave plenty of water to drink and had his patient frequently sponged

Dr Taylor thought that the statistics of the London fever hospitals pretty conclusively prove that a large percentage of cures of rheumatism had been effected since the introduction of salicylic acid

Dr J B Hamilton said it was of primary importance to ascertain the cause of the fever If it were due to increased tissue changes, it would be well to retard such changes The experiments with antipyrin had not been carried on long enough to enable us to estimate its true value He thought it hardly fair to call it a patent medicine, though its process of manufacture had been patented

Dr Hagner thought we should not use such violent remedies of whose secondary effects we know so little To get the temperature down should not be the prime mover of our treatment We did not endeavor to get the eruption of scarlet fever off the skin when in the natural course of the disease it should be present

Dr Taylor asked if Dr Hagner did not endeavor to check the diarrhœa of typhoid fever?

Dr S C Busey said he was the first, perhaps, to use antipyrin in this city He had intended using it in the case of a child, but was unable to get any of the drug until too late The patient died The next case was one of erysipelas The man's face and scalp were invaded by the disease He was a steady drinker, though perhaps he would not be called a drunkard Despite quinine his fever rose higher and higher until it reached 105° F He was thought to be dying, and was in fact comatose It was impossible to arouse him Sixty grains of antipyrin, in three powders, given at intervals of two hours, reduced the temperature to 99° F, markedly decreased the pulse rate, and the man became conscious He gave him fifteen-grain doses the next day, and continued the use of the drug for several days The fever never ascended and the patient got well

The next case was one of scarlet fever The patient had a temperature of 104°, and convulsions supervened He gave antipyrin, and later added bromide of potassium The temperature descended to 102°, but the next morning it ascended to 104°, and the patient died He had used the drug in other cases with varying success He had found the depression to last from three to twelve hours He had not, however, given the drug in full doses He would not hesitate to use it in some cases of hyperpyrexia He was sorry to hear Dr Hagner say that every high fever was normal, that he feared to use a drug lest it might intercept its course There are but few drugs, perhaps, whose use is unattended by danger He thought the antipyretic treatment of fevers was generally conceded to be proper A very large experience over the whole world tended to show the value of this method of treating fevers By doing so, complications and other dangers were lessened In croupous and catarrhal pneumonia fever is a considerable element of danger In the exanthematic the fever range is due to the amount of poison Would anybody tell him that a difference of only a half degree between the high maximum and the high minimum of a typhoid fever curve was beneficial? Fever is the factor which exhausts the heart To its influence are due the pathological changes in the muscular fibres Constitutions vary as to their susceptibilities to fever One patient will stand a temperature of 105° as well as another will a temperature of 102° Shall we let one as well as the other run its course? Shall we, through fear, permit parenchymatous changes to occur? Dr Hagner says he prefers the use of cold water Experience teaches that the cold bath is more dangerous than therapeutic remedies Hæmorrhage in typhoid fever is more apt to occur after a cold bath It is better to control the faculty of heat production than to rapidly dissipate it It is for that reason Dr Hagner considers quinine the safest drug Antipyrin seems to dissipate heat Such, indeed, is the theory of heat reduction by diaphoresis

Dr Hagner said from the remarks of the last speaker anybody would suppose that he, Dr Hagner, recommended the elevation of temperature, or at least the application of heat, in the treatment of fever He reiterated his former statement that we have no right to use new remedies without knowing exactly their action on the heart He had seen a child nearly killed by salicylate of soda We do injury by using violent remedies He contended that certain diseases have a natural high type

Dr King said there was no doubt that many diseases have a natural course Among the phenomena of fever is thirst which calls for cool water This should be given *ad libitum*, even if emesis is produced, for it is better to use nature's remedies than poisons But all natural processes are sometimes apt to get beyond the control of nature If enough cool water, air, etc, could be procured, we would rarely need other remedies It is right to let nature alone whilst the disease keeps within limits, but wrong not to check disease by therapeutic means when natural remedies are insufficient

Dr Acker had sought to lower the temperature with antipyrin, but not to bring it to a normal point He stated that rheumatism had been treated by this drug with happy effects without subsequent heart complications He had used antipyrin in the treatment of typhoid fever, and thought it had not affected the heart He had not found the pulse reduced, either in frequency or force

Dr W W Johnston thought there were two important questions embraced in Dr Hagner's statement, one as to the natural processes of disease, the other as to the use of new remedies When we undertake to treat symptoms we may do harm For example, before the use of the clinical thermometer the pulse was most carefully watched, and it was a prevalent idea that in high fever the force and rate of the pulse must be reduced For that reason veratrum viride was given in pneumonia Such a method of treatment is now abandoned, for it is believed that to sustain life it is necessary to have a strong and rapid pulse in order to drive the blood through the lungs of a man suffering from pneumonia He then related a fatal case in point, which he had seen in consultation, in which veratrum viride had been given, where the autopsy found a strong pulse to have been necessary and veratrum viride worse than useless As to Dr Hagner's statement that fever is a necessary element of some diseases, it is stated in Pepper's "System of Medicine," on what authority Dr Johnston did not know, that a high temperature may be necessary to destroy the germs The patient, however, may be destroyed at the same time The prevalent theory now is to bring down temperature Drugs which affect the heat centre are at times useless, for heat is caused by other reasons In typhoid fever, whilst the intestinal catarrh continues, these antipyretics will be local irritants As to the use of new remedies, it may be unwise and dangerous to prescribe them until their true value be known He had had a very disagreeable experience with jaborandi In a certain case of scarlet fever he desired to use a drug which would cause perspiration Jaborandi was given, but so great a secretion was excited from the fauces that the patient literally died of suffocation Antipyrin causes salivation in the dog, hence he would hesitate to use it in scarlet fever He thought the giving of a daily dose of quinine in typhoid fever to prevent the evening rise, may involve error He did not wish to be understood as speaking against antipyretic treatment

Dr Fry thought the question under consideration had two aspects We must first determine whether we have a sthenic or asthenic disease to treat It would be injudicious to choose aconite or veratrum viride to reduce the pulse rate when we need digitalis And so it may be dangerous, in fevers having an asthenic type, to use an antipyretic which has a sedative effect on the action of the heart In alcohol we possess an agent which supports the action of the heart while, by diminishing tissue waste, it reduces temperature

Dr Adams in closing the debate, said antipyrin is as well known as any other drug which is on trial He judged of the effects of temperature by the cerebral symptoms, and such symptoms would influence him in the use of antipyretics He would not be afraid to use antipyrine in scarlet fever with a high temperature He did not believe the drug had any effect on the pathological processes

Stated Meeting, October 28, 1885

The President, W W Johnston, M D,
in the Chair

Dr J Taber Johnson presented

UTERUS AND TUMOR REMOVED BY SUPRA VAGINAL HYSTERECTOMY

Mrs W, aged 35, white, married, the mother of one child 8 years old, was brought to my office in June last by Dr Walter, who gave me the following history of her case

In November, 1884, she noticed an enlargement in her right side, and discussed with her mother the probabilities of pregnancy She had too frequent and profuse menses, however, and the feeling gradually grew upon her that the growth in her abdomen was a tumor Her health continued very good She suffered no inconvenience from the growing tumor except from its weight and size There was a noticeable interference with the functions of the bladder and rectum, but no more than had occurred during her pregnancy eight years ago In April or May she consulted Dr Walter, who, under the suggestion that she might be pregnant, declined to use the sound, and as her health was not suffering, advised only symptoms should be treated, and that time would prove whether she was with child or not

Dr Walter brought her to my office on the 27th of June, when I diagnosticated an ovarian tumor, with fluid so thick that fluctuation was difficult or impossible to detect, and suggested operation at once, or as soon as the hot weather should be passed This was readily agreed to, and the first week in October appointed for the removal of the tumor I made several examinations in the meantime, and believed the tumor to be cystic from its general feel, but could never get any fluctuation I suggested that the fluid might be colloid, in its etymological sense I had no thought of malignancy, the patient being robust, of good color, good appetite, and feeling perfectly well She had not lost flesh, and had no cachexia

During the meeting of the American Gynecological Society I requested one of its distinguished members, who has performed and witnessed hundreds of abdominal sections, to examine Mrs W with me He kindly did so, and expressed a very positive opinion that the tumor was a solid fibroid, and as it was rapidly growing, that the proper operation was the removal of the uterine appendages, with the hope that the tumor would stop growing and soon disappear

This change of plan was explained to the patient and her husband, and October 7 fixed for the operation The lady was admitted to a private room in Providence Hospital on the 5th, and the abdomen was opened on the morning of the 7th in the presence of Drs Bromwell, Walter, Cutts, and the resident physician, Dr Hickling

When the abdomen was opened, instead of a solid fibroid I found a tense cyst, which was free from adhesions as far as could be ascertained with the finger or a large mole sound passed freely in all directions over the anterior surface of the tumor The tumor was tapped and about eight pounds of clear amber-colored fluid withdrawn Traction was made on the cyst, but it would not come Upon passing in my hand after enlarging the opening from the umbilicus to the pubic, it became apparent that the tumor was attached posteriorily over its entire surface

The separation of these very numerous and powerful adhesions occupied more than an hour They were so strong that it required nearly my entire strength to break them and lift the tumor out of its bed and to turn it out of the abdomen The difficulty seemed so great that at one time I thought of enlarging the opening, putting in a drainage tube, and stitching its edges to the abdominal incision, with further efforts, however, I was able to turn out the entire tumor It was then found that the attachments to the uterus were so intimate that they could not be separated without producing great hæmorrhage, and the removal of the uterus was finally determined upon

The clamp was then applied at the internal os, and the uterus and tumor were cut away with the thermo cautery knife The stump was secured in the lower angle of the wound, and the incision in the abdominal wall closed with eight silk sutures, after clearing out the abdominal and pelvic cavities a drainage tube was put in above the pedicle The usual dressing was applied, and the patient put to bed after being on the table two hours and twenty minutes I feared the lady would not live twenty-four hours, and so informed her husband

She, however, had a good night, and has continued to do well from that day to this Her highest pulse was 108, and temperature 101°, and that only for one day Her pulse has not been above 80 for two weeks, and her temperature has not been more than one degree above normal during that time The drainage tube permitted the removal of an ounce of bloody serum the first day or two The quantity grew less and less until on the seventh day none could be drawn up, and it was removed The pedicle and clamp came away on the fourteenth day, since which time the improvement has been rapid, and now, three weeks from the operation, the patient is sitting up in bed and eating a liberal diet She looks and feels well, She cannot use the bed pan, and now gets up and sits upon a commode by the side of the bed

From the appearance of the cyst and its contents I feared that there was a colloid degeneration of the tumor, and therefore took it to the Army Medical Museum for examination, and I regret that I cannot present a better outlook for the future of the brave lady who has been through such a trying ordeal

The following is the report of the microscopist of the Army Medical Museum

War Department, Surgeon General's Office,
Army Medical Museum,
Washington, D C, Oct 27th, 1885

J Tabor Johnson, M D

Dear Doctor —The abdominal tumor sent here for examination proves to be a cystic adeno carcinoma of the ovary, the diameter of the cysts ranges from 1 200 to 1 20 inch, and they are lined with columnar epithelium, which is ciliated in most of the cysts, they are filled with degenerated mucoid tissue, which has scattered in it large epithelial cells Besides the cystic formation, there is a decided cancerous infiltration which occurs in patches, and has the appearance of a cylindrical epithelioma. The uterus is also infiltrated with the carcinoma, but has not undergone cystic degeneration

Respectfully, W M Gray

While a reference to the statistics of supra-vaginal hysterectomy is not in place in a report accompanying a pathological specimen, still a few words on this subject may be pardoned The impression prevails, I think, that this is a very fatal operation when performed, as it usually is, for the removal of uterine fibroids, and yet Keith has recently reported thirty-eight cases of the removal of the uterus above the internal os, along with fibroid tumors—the average weight of which was fourteen pounds—with only three deaths, or a mortality of about eight per cent In the last edition of his book, Sir Spencer Wells gives the results after hysterectomy in thirty-nine operations with twenty nine deaths In Bigelow's tables, which were supposed to place conveniently on record all published cases up to the date of his paper, there were 359 operations with 227 recoveries and 132 deaths These operations were done in all parts of the world, and in many cases in series of twos and threes by inexperienced operators, and hence this great mortality

It would seem that the greatest success is attained by those who have had a large experience in ovariotomy Thus Keith remarks that he trembles to think what would have been the fate of the women he operated on had it not been for the experience in abdominal surgery gained in the performance of ovariotomy Knowsly Thornton gives similar testimony In 1882 Thornton reported twenty five cases of removal of uterine tumor, with nine deaths In 1883 he read a paper in Liverpool on this subject in which he reported six additional operations with only one death Within a few weeks Mr Thornton has sent me another paper in which he reports thirty eight new cases of supra vaginal hysterectomy with only two deaths Keith says that Bantock is by far the most successful of all the London operators, and his numbers are the largest

Lawson Tait, Schrœder, and Hegar have also had wonderful results in this operation when compared with earlier experience For the relief of the ordinary uterine myoma oophorectomy, or Tait's operaation, offers the greatest safety and best results Tait recently reports fifty-eight cases of Tait's operation during the last year for myoma, with success in every case, and adding the previous year's experience of fifty cases, makes a a series of 108 oophorectomies with but two deaths There are certain cases, however, which demand surgical relief, which can only be obtained by supra-vaginal hysterectomy, and it is a satisfaction to see the statistics of this very formidable operation improving.

Dr. Johnson also presented a

UNILOCULAR CYST OF THE OVARY.

This is a case of simple unilocular ovarian cyst which was removed last Thursday morning from a lady in Providence Hospital. There is little of interest connected with it, except that there were firm and dangerous adhesions to the vermiform appendix and to the intestine just below it. She and her husband both inform me that she was not long ago under the care of a gynecologist who assured them positively, both verbally and by letter, that there was nothing the matter except an unusual deposit of fat. The cyst and contents weighed just twelve pounds.

The lady, Mrs. P., 23 years of age, is the mother of two children, the youngest being 4 years old. Had a miscarriage three years ago, since which time she has been slowly increasing in size. She came to me from Fall's Church, Va. Drs. Lincoln and Busey agreed with my diagnosis, and with me recommended immediate operation. I sent this lady to Providence Hospital on Monday week, and operated on the following Thursday morning, in the presence and with the assistance of Drs. Hamilton, Cutts, Cuthbert, and the resident physician. The patient rallied well and has not had a symptom of any kind. Her highest temperature has been 100 and her highest pulse 92. She has had no pain and has taken no medicine except one suppository of 10 grs. of quinia and ¼ gr. morphia just after being placed in bed—and that was unnecessary. She is now in her seventh day.

FOREIGN CORRESPONDENCE.

LETTER FROM PARIS.

(FROM OUR OWN CORRESPONDENT.)

Lateral Deviation of the Phalanges of the Index Fingers—The Action of Alcohol, Pepsin, and Alkalies on Digestion—Inoculability of Varicella.

A curious example of teratology was recently brought to the notice of the Academy of Medicine in a family consisting of a mother and three children, who were all four the subjects of the same malformation, viz.: lateral deviation of the phalanges of both index fingers. It would appear that such another example of this deformity has never been recorded, and of course some explanation was looked for. The deformity was evidently hereditary, as the subjects had not been injured, nor are they rickety. An explanation was proffered by the mother, who stated that her mother's mind was frequently impressed, during her pregnancy, with the form of a lobster, the claws of which offer some analogy with her deformed fingers and those of her children. Moreover, the mother had suffered great anxiety lest her offspring should be born with the same deformity; this idea preyed so much on her mind that she declared that if she had another child with the same deformity she would commit suicide.

M. Guérin considered this malformation to be purely articular, and believed that by dividing the lateral ligaments, which appeared to him to be the immediate cause of the deformity, the fingers could be straightened. M. Trélat, however, does not consider the deformity as being due to an articular lesion, but thinks that it is of an osseous nature, so that M. Guérin's remedy would be of no avail. Moreover, the deformity being manifestly hereditary, it would be useless to perform any operation in view of overcoming its transmissibility, as such deformities are of the nature observed in some of the lower animals, and which constitute fixed types among them, as is the case with dogs with crooked legs and tails. But when the deformity is accidental or artificial it is not transmissible.

After a communication made by M. Vigier at the Société de Thérapeutique on the action of alcohol, pepsine and alkalies on digestion, a debate took place, the conclusions of which may be summed up thus: 1. The ingestion of a small dose of alcohol increases the acidity of the gastric juice, and, as a consequence, may assist digestion in subjects whose gastric juice may be deficient of acidity, and becomes injurious in the opposite condition. 2. Care should be taken not to associate the bicarbonate of soda or of magnesia in any digestive powder containing pepsine. Dr. Dujardin-Beaumetz remarked that alkalies administered in strong doses (5 to 6 grammes) destroy the gastric juice, as was shown by M. Richet. Consequently, the physician should avoid prescribing mineral waters containing that quantity of the bicarbonate of soda, as in that case they can only produce bad results as far as the digestion is concerned.

At a recent meeting of the Societe Medicale des Hôpitaux, a debate took place on the inoculability or non-inoculability of varicella. Dr. Dumontpallier, after a long argument, came to the following conclusions: 1. Varicella is a specific malady distinct from variola and vaccina. 2. Varicella is a contagious malady, but not inoculable. A. B.

DOMESTIC CORRESPONDENCE.

LETTER FROM NEW YORK.

(FROM OUR OWN CORRESPONDENT.)

Progress in Bright's Disease—Electricity in Gynecology—Relations of Physiology to Medicine—The State Medical Association; Address in Physiology; Address in Pathology; Election of Officers; the Library; Treatment of Spondylitis.

The last meeting of the New York County Medical Association, which was held at the Murray Hill Hotel on the eve of the meeting of the State Association, was one of great interest. On this occasion Professor Austin Flint read one of those characteristically clear and comprehensive papers for which he is so noted, expressed in the terse and lucid diction of which he is so complete a master. His subject was "Elements of Prognosis in Bright's Disease," and, as might be supposed from his extended and ripe experience, it was one on which he could speak with authority. Having referred to the prevalent notion that an individual with Bright's disease was in the situation of a criminal condemned to death, and even in a worse predicament, from the fact that there was always a possibility of the latter securing a pardon or reprieve, he went on to speak of the circumstances which in many instances would be likely to modify the prognosis. Acute nephritis, he said, was not, as a rule, followed by the chronic form of the disease, nor characterized by any renal lesion; and the same was true of the subacute nephritis, such as often follows scarlatina, for instance. It was to be remembered, also, that an acute, diffuse tubular or desquamative nephritis might be met with as an intercurrent affection in the course of chronic Bright's disease. Under such circumstances a problem was presented which could not at once be definitely settled, since we could not be certain whether the grave symptoms noted were connected with the chronic trouble or whether they were significant of an acute attack of nephritis which would soon subside, and leave the patient in the same general condition as before. It was to be noted, however, that when an attack of the latter kind did occur, it was very apt to leave the patient with a tendency to recurrent trouble of similar character.

In chronic Bright's disease the affection might remain latent for a long time. In order that the prognosis might be a comparatively favorable one, when it had declared itself, it was necessary that the kidneys should not be damaged beyond a certain point, and that the important organs of the body other than the kidneys should be capable of satisfactorily performing their functions, while the laws of health in general were carefully observed. If these conditions were maintained, even though the kidneys were damaged to the extent of one-half, the patient might continue to live in a fair state of health. Chronic Bright's disease might exist, without discomfort to the patient, for years, and then at length the pathological process in the kidneys involve the organs to such an extent that they could no longer perform their functions; or, the accessory conditions might become sufficiently changed to give rise to serious trouble. The object of treatment, therefore, was to prevent further advance of the disease in the kidneys and to maintain favorable accessory conditions. In view of these facts, it could be readily seen how important it was to make an early diagnosis. The diagnosis made, the essential point was to see that a sufficient elimination of excrementitious products was carried out by the kidneys. It was very easy to determine whether the elimination was sufficient or not by simply ascertaining the quantity of urine passed in the twenty four hours, and testing the specific gravity with the urinometer. If it was found that there was renal adequacy, the indication for diuretics, sudorifics, and hydragogue cathartics was not present, and they would only do harm.

The diminution of excrementitious eliminations was not a necessary indication of danger from uræmia, because vicarious elimination might take place and tolerance thus be established. The prognosis of uræmic coma in chronic Bright's disease was naturally grave; but at the same time patients not infrequently recovered from it. It might possibly be due to an intercurrent attack of nephritis, or to the fact that tolerance was not established in the system. When there was pulmonary œdema and dyspnœa, there was a chance of the patient's recovery; but if there were present what is known as renal asthma (which is not due to any condition of the lungs whatever, but in all probability to the effect of a poison upon the nerve centres), it was to be regarded as of fatal import.

At the meeting of the Academy of Medicine on November 5, Dr. Paul F. Mundé read a practical paper on "Electricity as a Therapeutic Agent in Gynecology," the object of which, he said, was to popularize, so far as he was able, this method of treatment in the department of medicine in question. In the introductory part of it he referred to the following points as of importance to remember in this special application of electricity:

1. The galvanic current is far more generally useful than the faradic, which, as a rule, has a stimulating effect, while the galvanic acts as a sedative.

2. A mild, steady current will answer every purpose better than a powerful interrupted one. The faradic current, on the other hand, is useful in proportion to its strength.

3. Whenever the constant current causes pain, it is doing harm.

4. It is of little consequence which pole is placed within the body, provided care be taken that the current is not too strong. There is, however, one marked exception. In cases in which there is circumscribed pain, the positive pole is the one to be placed near the painful point.

5. It is safest to begin with a very weak current, and gradually increase its strength to any desired point.

6. When internal electrolization is to be employed, it is always best to introduce the internal pole upon closing the connection, on account of the sensitiveness of the external parts.

7. To be of any service, it is necessary that the treatment should be continued for a long time. As a rule it is quite useless to make applications less frequently than twice a week, and in many cases they should be made every other day. The treatment should last for from three to six months.

8. The results of faradization in chronic affections are less favorable than those of galvanism; but, while relief from pain and an amelioration of the general condition is very often obtained by this means, a complete cure is usually not to be looked for.

Dr. Mundé then spoke of a number of conditions in which he had employed electricity with considerable success. In speaking of its use in subinvolution, he said that when the case was of recent date and attended with menorrhagia, the faradic current was indicated; but afterwards the galvanic was the one to be used, although it was not advisable to introduce the electrode inside the uterus. In speaking of chronic inflammation of the ovaries and Fallopian tubes, he said the only *cure* was salpingo oophorec tomy In Tait's hands this had proved an operation comparatively free from risk, but no other operator had met with the same extraordinary success In addition to the danger under ordinary circumstances, however, there was a grave objection to subjecting young married women to an operation which deprives them of all hopes of offspring, especially as there was a possibility of pregnancy occurring The radical operation should be deferred, therefore, until all other measures had failed to give any relief, except in those cases in which imminent danger to the patient calls for its prompt performance He had seen very great benefit derived from palliative treatment, and the use of electricity was often of important service in supplementing other local measures

In speaking of the treatment of uterine fibroids by electrylosis, he referred to a case of Dr Fowler, of Brooklyn, which he saw in consultation, and which was afterwards reported cured by this method Dr Fowler was present at the Academy, and in the discussion which followed the reading of the paper he related the details of this case, and also reported two or three others which had been cured by the treatment

The conclusions which Dr Munde gave at the end of his paper were somewhat as follows

1 Electricity is a valuable agent in gynecology, and one which deserves to be much more frequently resorted to than is now the case

2 Its application in gynecological practice does not require special skill in the use of electricity

3 The remedy, if properly used, cannot do harm

4 It is of especial service in chronic conditions, and no pain is caused if the galvanic current is employed

5 The faradic current is indicated in deficient development and want of tone in the sexual organs

6 The galvanic current is to be used for the purpose of promoting absorption of adventitious products and allay pain

7 This method of treatment requires perseverance and the exercise of much patience

8 It is contra-indicated in acute and sub acute inflammatory conditions

9 The pathological conditions in which electricity proves useful are those in which other treatment often fails, or cannot be borne by the patient

10 In organic diseases a permanent cure or a restoration of the diseased organs to perfect health cannot be expected, but very marked relief, and that without danger, may often be afforded by means of electricity

At the recent meeting of the State Medical Association, the Address in Physiology, entitled "Some of the Relations of Physiology to the Practice of Medicine," was delivered by Prof A Flint, Jr A considerable portion of it was devoted to the bearing of the examination of the heart in health on that of the heart in disease, and the importance of an accurate knowledge of cardiac physiology in judging of the pathological condition of this organ When, he said, a student had fully mastered the physiology of the heart the recognition of abnormal sounds was easy, but without this thorough knowledge, the whole matter was a sealed book Indigestion and dyspepsia in their various forms constituted a class of affections which it was not easy to treat intelligently, and the more extensive the physician's knowledge of the process of digestion in all its details, the more successful would be his practice in this field Having referred to the benefit to medical science which physiology had conferred in the matter of localization in the encephalon and the discovery of the sugar making function of the liver, he went on to speak of the practical bearing of the knowledge of heat-production in the animal economy for which we were indebted to the physiologist Now it was the custom to feed fevers in order to supply the excessive demand for heat production, and thus effect the conservation of the vital forces This by no means increased the body temperature, but, on the other hand, actually reduced it Alcohol was therefore, of the highest possible advantage in appropriate cases, and one ounce of good French brandy represented a value of no less than thirty-four heat-units Under such circumstances it was undoubtedly consumed at once in the system, and hence might be given in large quantities without any injurious consequences, when the same amount given in health would pass to a large extent into the blood, and produce intoxication

He then spoke of the use of the hydrocarbons in phthisis, and of the abnormally low temperature met with in diabetes, after which he touched upon the subject of vaccination, the discovery of which Jenner had described as distinctly physiological The conclusion of the address was devoted to some consideration of the modern application to pathological investigation of the methods which had long been practised in physiological research, and which had led to the greatest discovery in pathology since that of vaccination, Koch's demonstration of the bacillus tuberculosis having opened up a field which was illimitable in extent Henceforth physiology and pathology would go hand in hand, and the ideal pathologist would be profoundly versed in physiology no less than the ideal physiologist would be profoundly versed in pathology

The Address in Pathology was delivered by Prof Edward G Janeway, who gave a *resume* of the latest advances in this department, and in speaking of the growing interest in the subject of micro organisms which was now manifested by the profession in this country, made a strong plea for the desirability of admitting scientific books and apparatus into the United States free of duty Most of the young men who were devoting themselves to pathological research here were poor, and he thought it disgraceful that it should be necessary to pay for a microscope in New York just what the same instrument would cost in Germany Was it not time, he asked, that some one was memorializing Congress on this subject?

The officers of the Association elected for the ensuing year were as follows President, Dr E M Moore, of the Fourth District, Vice-Presidents, Drs Wm Gillis, First District, H C Van Zandt, Second District, Frederick Hyde, Third District, and D Guernsey, Fifth District, Recording Secretary, Dr Caleb Green, of Homer, Cortland County, Corresponding and Statistical Secretary, Dr E D Ferguson, of Troy, Treasurer, Dr J H Hinton, of New York, New Members of the Council, Drs E M Lyon, 1st District, I H Abell, 2d District, T W Ross, 3d, S T Clark, 4th, and E S F Arnold, 5th District

Dr J W S Gouley, of the Committee on Library, reported that there were now in the library, which occupies a commodious chamber in the Carnegie Laboratory building, no less than 3,450 volumes and medical journals, and that it contained many rare and valuable works and complete sets of many important journals Much praise was due to Dr E F F Arnold for his self-denying labor in arranging and cataloguing the collection At the last session of the Association, the Corresponding Secretary announced that next year the work of the annual meeting would be so arranged as not to occupy more than three days, and that at least one evening of the session would be left entirely free

The meeting was brought to a successful close by a most attractive clinical lecture, at the Carnegie Laboratory, by Prof Lewis A Sayre, on the "Treatment of Spondylitis or Caries of the Spine by partial suspension and the plaster-of-Paris jacket, and the Treatment of Rotary Lateral Curvature by Gymnastics and partial Suspension, and the Plaster-of-Paris Corset" The reason for giving such a demonstration at this late date was, he said, that although the matter had been repeatedly brought to the attention of the profession, it was still evident that the practical application of the methods which he had so long inculcated was still very imperfectly understood by the great mass of practitioners These methods had received the cordial approval of the highest authorities in orthopædic surgery in every civilized nation in the world, and yet one could read in the twentieth annual report of a large public institution in the city of New York especially devoted, to a large extent, to the treatment of the class of deformities involved, the statement that "the use of extension for disease of the joints or the application of the plaster-of-Paris jacket was never allowed in the hospital" Though the individual opinion of the medical man in charge of this institution might not be of much consequence, it became a serious matter when this opinion became endorsed (as it was by their names appearing on the consulting staff of the hospital) by some of the most distinguished surgeons in the city or the country Again, he said, scarcely a day passed but what some patient was brought to him from a distance, who had been suffering the greatest agony from the defective mechanical devices which had been employed in the treatment of his deformity Yet these were almost invariably immediately relieved when a proper dressing was applied in the case, and great expense, time and trouble might have been saved if the patient's physician at home had only been taught how to successfully deal with such cases The methods of treatment referred to in the title were fully explained and practically demonstrated, both in Potts' disease and lateral curvature, the objections which had been raised to them in certain quarters were shown to be without weight, and a large number of striking cases were exhibited by way of illustration P B P

BOOK REVIEWS

A SYSTEM OF PRACTICAL MEDICINE, by American Authors Edited by WILLIAM PEPPER, M D, L L D, Assisted by LOUIS STARR, M D, etc Vol III Diseases of the Respiratory, Circulatory, and Hæmatopoietic Systems 8vo, pp 1032 Philadelphia Lea Brothers & Co 1885

The third volume of this great work, which attained a merited popularity immediately on the issue of the first volume, is in no way inferior to its predecessors It contains forty seven articles, by twenty-seven authors The volume opens with an article on "Laryngoscopy and Rhinoscopy," by Carl Seiler, M D, which occupies over twenty pages This is followed by Dr Harrison Allen's article on "Diseases of the Nasal Passages" Dr Hosmer A Johnson contributes the paper on "Neuroses of the Larynx," which is followed by two papers from the pen of Dr A Jacobi "Acute Catarrhal Laryngitis," and "Pseudo-Membranous Laryngitis" Dr Elsberg is the author of the articles on diseases of the larynx and trachea Dr Lefferts devotes nine pages to a consideration of tracheotomy Dr N S Davis writes of the "Diseases of the Bronchi," in twenty pages The two articles on "Bronchial Asthma" and "Hay Asthma" are by W H Geddings, M D, and the four following, on "Dilatation of the Bronchial Tubes," "Emphysema," "Collapse of the Lung," and "Congestion and Œdema of the Lungs," are by Dr Samuel C Chew Dr William Carson is the author of the four papers on "Hæmoptysis," "Pulmonary Apoplexy," "Abscess of the Lung," and "Gangrene of the Lung" The papers on "Croupous Pneumonia" and "Catarrhal Pneumonia" are respectively by Dr Alfred Loomis and the Editor, Dr Pepper Dr Beverly Robinson contributes the article on "Pulmonary Embolism," Dr Austin Flint, Sr, that on "Pulmonary Phthisis," Dr E T Bruen those on "Syphilitic Disease of the Lung," "Pneumonokoniosis," "Cancer of the Lungs," and "Pulmonary Hydatids" The paper on "Acute Miliary Tuberculosis" is by Dr John S Lynch, and that on "Diseases of the Pleura" by Dr Frank Donaldson

The Diseases of the Circulatory System are treated of in twelve articles, covering 260 pages, as follows "Diseases of the Substance of the Heart," by William Osler, M D, "Endocarditis and Cardiac Valvular Diseases," by Alfred L Loomis, M D, "Cyanosis and Congenital Anomalies of the Heart and Great Vessels," by Dr Morris Longstreth, "Cardiac Thrombosis," by Dr Beverly Robinson, "Neuroses of the Heart," by Dr Flint, "Diseases of the Pericardium," by Dr Da Costa, "The Operative Treatment of Pericardial Effusions," by Dr John B Roberts, "Diseases of the Aorta," by Dr G M Garland, "Diseases of the Coronary, Pulmonary, Superior Mesenteric, Inferior Mesenteric, and Hepatic Arteries, and of the Cœliac Axis," by Dr Elbridge G Cutler, "Diseases of the Veins," by Dr Andrew H Smith, and "Diseases of the Mediastinum," by Dr E T Bruen

The remainder of the volume is concerned with the Diseases of the Blood and of the Hæmatopoietic System, four articles, on "Diseases of the Blood and Blood-Glandular System," by Dr. Osler; "Diseases of the Spleen," by Dr. I. Edmondson Atkinson; "Diseases of the Thyroid Gland," by Dr. D. Hayes Agnew; and "Simple Lymphangitis," by Dr. S. C. Busey.

We must regret that an extended consideration of these papers is impossible in the space at our command. The contributors are so well known, however, that such consideration is by no means necessary. This "System Medicine by American Authors" is a monument to American Medicine.

Practical Therapeutics. A Compendium of Selected Formulæ and Practical Hints on Therapeutics. Interleaved. By Edward J. Bermingham, A.M., M.D., etc. 8vo, pp. 420. New York: J. R. Bermingham. 1885.

If books of this class could be kept out of the hands of those who use prescriptions as mathematicians use algebraic formulæ, they might be of considerable value. In this book, under the head "Neuralgia," we find seven formulæ. The reader is left to infer the causes of the neuralgia requiring any particular formula, and if a particular case be due to malarial influence he might experiment, successively with all and fail to relieve his patient. The only prescription for tetanus is a hypodermatic injection of ten drops of a solution of gr. ij of woorari to gtt. c of distilled water, every four or five hours. It would be interesting to know how many cases of tetanus have been cured by this treatment. For the treatment of insomnia Brown-Séquard's old bromide prescription is recommended—nothing else. For whooping-cough we recognize an even dozen old friends—no new ones. For the so called congestive chill we find two, the first valueless, the second containing too much atropia and too little morphia. We believe the tendency of such books as this to be mischievous. The intelligent practitioner who studies does not need them and others should not have them.

Lectures on the Diagnosis of Diseases of the Brain. By W. R. Gowers, M.D. 8 mo, pp. 253. Philadelphia: P. Blakiston, Son & Co. 1885.

These lectures were delivered at University College Hospital, London. They are most excellent. The author discusses briefly and closely the anatomy and physiology of the brain as far as they throw light on the diagnosis of cerebral diseases.

He then takes up the various symptoms of brain disease and discusses their cause and their value in forming a diagnosis. The last lectures in which he considers the "diagnosis of the nature of the lesion," "the pathological diagnosis of sudden lesions" and of "chronic lesions" are particularly interesting, because they are eminently practical and clear. The book is not a large one. It comprises eighteen lectures, covering less than 240 pages. It is well worth reading by students and general practitioners. The interest of the subject and the clearness and conciseness of the author recommend the book to all.

INTERNATIONAL CONGRESS.

SPECIAL ANNOUNCEMENT.

The Executive Committee of the Ninth International Medical Congress, to be held in the City of Washington, D. C., commencing on the first Monday in September, 1887, having accepted, under Rule 10 of the Committee on Preliminary Organization, the charge of the business of the Congress, hereby give notice to the members of the medical profession that they have been actively engaged upon, and have now nearly completed the arrangements for this meeting, and they anticipate the hearty cooperation of the profession everywhere in developing this great scientific and humanitarian assembly.

By order of the Executive Committee.

Henry H. Smith, M.D., Philadelphia,
Chairman of Executive Committee.
Nathan S. Davis, M.D., LL.D.,
Secretary-General of Ninth Int. Med. Congress.

Chicago, Nov. 24, 1885.

CAMDEN COUNTY MEDICAL SOCIETY.

At the semi annual meeting of the Camden County Medical Society, held November 10, 1885, the following resolutions were unanimously adopted:

Resolved, That this Society approves of the action of the American Medical Association in enlarging the Committee of Arrangements for the Ninth International Medical Congress, in 1887.

Resolved, That the Rules regulating the membership and business of the Congress adopted by the Committee of Arrangements at the meeting in New York, September 3d and 4th, and the transference of the future management of the Congress to an Executive Committee, composed of the President of the Congress, the Secretary General, the Treasurer, the Chairman of the Finance Committee, and the Presidents of Sections, be considered by this Society sufficient to silence criticism and enlist the sympathies and support of the profession throughout the United States.

Resolved, That the Secretary be instructed to forward copies of these resolutions to the County Medical Societies of New Jersey.

E. B. Woolston, M.D.,
President.
H. Genet Taylor, M.D.,
Secretary.

Camden, N. J., Nov. 10, 1885.

ASSOCIATION ITEMS.

INFORMATION OF IMPORTANCE TO ALL MEMBERS OF THE AMERICAN MEDICAL ASSOCIATION.

Membership.—Every one who attends an annual meeting of the Association as a delegate pays at that time five dollars, and thenceforward becomes a Permanent Member. He continues as such as long as he remains in good standing in the body from which he was originally sent as a delegate. As a Permanent Member, he must pay *Five Dollars Annually*, when notified by the Treasurer, whether he attends the meetings of the Association or not Payment of annual dues entitles him to receive the weekly Journal of the Association for one year

Members by Application are such as have not become Permanent Members in the manner above indicated, but apply to the Treasurer for membership, forwarding at the same time to him five dollars and the certificate of the President and Secretary of their State or local society, that they are in good standing in such society They pay five dollars annually thereafter, when notified by the Treasurer Members by application can join the Association at any time, and they receive regularly the weekly Journal

When Dues are Payable —The annual dues from Permanent Members are payable to the Treasurer at the time of the annual meeting of the Association, or immediately thereafter The payment entitles the member to receive the Journal for one year from the following July Payment for 1885, for example, entitles the member to the Journal from July, 1885, to June, 1886, inclusive

As some of the members have not yet forwarded to the Treasurer their dues for 1885, they are urgently requested to do so at an early day Having entered upon another year of membership, they are morally and legally responsible to the Association for the payment of their annual dues, having already received for three months of the new year—1885—the Journal of the Association

Subscriptions to the Journal, from those who are not members of the Association, should be forwarded to the office of publication, 65 Randolph Street, Chicago, and not to the Treasurer, but *all payments of annual dues must be forwarded to the Treasurer, Lock Box 1274, Philadelphia*

Deaths —When a member of the Association, who is in regular receipt of the Journal, dies, his family or other representatives are requested to inform the Treasurer at once of the fact

Payment of Dues for Previous Years —As a few members of the Association are still in arrears for payment of dues for 1883 and 1884, they are requested to forward at once to the Treasurer the amounts for which they are indebted to the Association

Transactions of the Association —These annual volumes, thirty three in number, to 1882 inclusive, may still be obtained, with few exceptions, from the Treasurer, at reduced prices The Index to these volumes will be forwarded on receipt of *One Dollar* An opportunity is thus afforded to complete sets of these valuable publications, or to obtain important papers and works which are daily becoming scarce

Richard J Dunglison, M D , *Treasurer*
Lock Box 1274, Philadelphia, Pa

MISCELLANEOUS

Vindication of the Secretary of the Michigan State Board of Health —Dr Arthur Hazlewood, chairman of the committee appointed on July 13, 1885, to investigate the office of the Board and the secretary, presented the written report of the committee at the recent meeting of the Board He and the other two members of the committee had examined the work of the office, the report of the Legislative committee on investigation, and he himself had made an unexpected visit to the office, and devoted some time to a thorough investigation The report showed how all expenses growing out of the Board were directly authorized by law and were reasonable, and expressed the confidence of the committee in the faithfulness of the secretary of the Board to the public health interests of the State The report was adopted The present year has been a particularly trying one for the office of the secretary of the Board Early in the year, at a time when extra work was needed, he was harrassed by false reports of investigations, and extraordinary demands upon the office have since been continuous, because of the fearful plagues of cholera in Europe, and small-pox in Canada, besides the increasing demands by local Boards of health and others throughout the State, for aid in efforts to control the preventable diseases most destructive in Michigan—diphtheria, scarlet fever, and typhoid fever

The next regular meeting of the Board will be on the second Tuesday in January, 1886

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT U S ARMY, FROM NOVEMBER 21, 1885 TO NOVEMBER 27 1885

Maj Anthony Heger, Surgeon, member of the Army Medical Examining Board now in session in New York City, is relieved from the additional duty of attending surgeon in that city, to take effect when Lt Col Jos R Smiths, Surgeon, shall have arrived in New York and entered upon that duty (S O 267, A G O , Nov 19, 1885)

Capt Walter Reed, Asst Surgeon, granted leave of absence for one month, with permission to apply for one month's extension, to take effect about Dec 1, 1885 (S O 115, Dept Platte, Nov 18, 1885)

Capt Arthur W Taylor, Asst Surgeon, granted leave of absence for one month, to take effect Dec 5, 1885 (S O 116, Dept Platte Nov 20, 1885)

First Lieut A R Chapin, Asst Surgeon, ordered for temporary duty at Ft Robinson, Neb S O 115, Dept Platte, Nov 18, 1885)

Lt Col James Simon, U S A (retired), died Nov 18, 1885, at Baltimore, Md

---

OFFICIAL LIST OF CHANGES IN THE MEDICAL CORPS OF THE U S NAVY DURING THE WEEK ENDING NOVEMBER 28 1885

R A Marmion, Surgeon, detached from Marine Barracks, Washington, D C , Dec 7, and wait orders

A M Moore, Surgeon, ordered to Marine Barracks, Washington D C , Dec 7, 1885

OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF MEDICAL OFFICERS OF THE U S MARINE HOSPITAL SERVICE FOR THE WEEK ENDED NOVEMBER 21 1885

Yemans, H W , Passed Asst Surgeon, Promoted to be Passed Asst Surgeon from Nov 1, 1885 Nov 14, 1885 Re assigned to duty at San Francisco, Cal Nov 16, 1885

McIntosh, W B , Asst Surgeon, appointed an Asst Surgeon, Nov 14, 1885 Assigned to duty at New Orleans, La Nov. 16, 1885

ORIGINAL LECTURES

ANNUAL ADDRESS BEFORE THE AMERICAN PUBLIC HEALTH ASSOCIATION

Delivered Tuesday Evening, December 8, 1885,
In the City of Washington, D C,

BY THE PRESIDENT, JAMES E REEVES, M D,

OF WHEELING WEST VIRGINIA

GENTLEMEN AND FELLOWS

By your kindly suffrages I have been clothed temporarily with the highest honor that can be conferred by sanitary workers in the United States, and I confess that I have reached the duties and exercises of this our thirteenth annual meeting, and the culmination of my official privilege and distinction, with many misgivings as to my ability to meet the full measure of your reasonable expectations

A man, it is true, may possess thoughts, sentiments, opinions, attachments, he may be animated by an ardent desire to recommend these to the belief, or to the approbation of others, but in order to recommend sentiments and opinions with success, it is indispensable that he shall be able to command those easy and natural graces, those soft insinuating arts of tone, of gesture, of expression, which must either be the gratuitous endowment of nature or the result of a long course of assiduous application and practice

A speaker is laboring under many disadvantages who has to encounter, on the one hand, all the negative influences which result from the want of a free and frequent intercourse with the world, from the want of a familiar acquaintance with the current terms and popular phrases—those silken approaches and passages to the heart by which the convictions of man are created or confirmed, while, on the other hand, he must encounter all the positive influences which result from a retired and silent life

Besides all this, you will admit that our profoundest feelings are always the most difficult to communicate, yet, at this hour, and in the presence of this large assembly of wise and good men who have come up from the North, the South, the East and the West—representing not only hundreds of cities and large towns in this great country of ours, but also the Canadas—bringing with them, to grace this auspicious meeting at the Capital of the Nation, priceless knowledge how to increase the duration and value of human life and elevate humanity to the highest standard of physical, mental and moral grandeur—I invite your attention to subjects which have encouraged the most industrious energies of my life namely, the Public Health, and, to that end, the usefulness and welfare of the American Public Health Association whose good name and honor have been committed to our care, and I trust it will not be in vain if I bespeak your kind indulgence while I refer to matters which I have had so much at heart for the last fifteen years

The success of our meetings has always largely depended upon the well directed energies of the local committees of arrangements, and I am sure every member of the Association present will join me in heartily extending to Dr Smith Townshend, chairman, and his distinguished associates on the local committee, many, many thanks for the excellent and attractive programme they have so liberally provided for our reception and entertainment during the hours of recess It promises, verily assures, "a feast of reason and flow of soul," and again it will be said, and justly, that the medical profession and the city authorities of Washington never do things halfway

But our greetings and congratulations are not unmixed with sorrow, for they link us closely with "the valley of the shadow of death!'" A great statesman, Thomas A Hendricks, the Vice-President of the United States—a great and good man in every phase of his life—has been suddenly and unexpectedly cut down from among the living, and the knell of the sorrowful tidings, on the evening before Thanksgiving, cast a shadow over the hearthstones of millions of his countrymen And this is not all of the sadness which on this occasion possesses our hearts Since the last meeting, six master workmen in the vineyard of sanitary science, of beautiful private character and solid professional attainments, have been called off from labor to refreshment, and I am filled with grief almost too full for utterance when I think of the loss this Association has sustained by the death of J G Thomas, of Savannah, F W Hatch, of Sacramento, Thomas I Neal, of Dayton, John J Speed, of Louisville, Richard McSherry, of Baltimore, and Thad M Stevens, of Indianapolis These dear names will never be forgotten, for they are indissolubly connected with the history of sanitary progress in the United States Having made their best offerings at the shrine of the Public Health, they then "took their burden for a pillow, and laid down by the wayside to sleep that dreamless sleep" that wakes in a glorious immortality! Peace, peace to their precious ashes! The terrible question that irresistibly presents itself—who of us shall be called next? cannot be answered Let us, therefore, be admonished by the uncertainty of life, and "work while it is called to day, for the night cometh when no man can work "

Every such an assembly as this moves forward another day's journey the ark of the sanitary covenant, and humanity is bettered and made happier thereby A body so numerous as the one here assembled, which extends its action and influence over every part of the national domain, and is intimately connected with all the interests of society, cannot meet to deliberate on its usefulness, its interests, and its dignity, without making its impress upon the great heart of society The ruling character of the nineteenth century is the tendency to perfecting the physical, intellectual and moral welfare of man In every civilized and progressive country, sciences, arts, private and general industry, everything, in fact, tends towards this end, every one is carried forward by this general movement of advance, men as well as governments And what are the obligations of organized government to its citizens concerning the security of the public health? It would be easy to present examples from the history of republics which have arisen and passed away in distant lands and in different ages, in proof of the *epidemic agency of bad government*, and as a warning to the rulers of our own dear land where a new social experiment is in progress, the fairest, the freest, the most hopeful of any upon which the sun has diffused his life giving radiance And what are the elements of this beauty, this freedom, this bright anticipation? The answer is, our own hallowed institutions, and another and far more important question should immediately follow—how shall they be preserved?

Hygeia has been called the hand-maid of liberty, and in illustration of this position historic examples could be furnished pointing out the diminished population, decay of agriculture and commerce, and increase and fatality of disease which ensued on the downfall of republics Knowledge of changes of this nature which followed the destruction of the republics of Etruria and Magna Græcia by Rome, and then noting those manifested when the latter abandoned the republican for the imperial and despotic government, should be embraced in the history studies of every common-school boy and girl in the United States In subsequent times, what a contrast between the face of the country, as described by Muratori, when it had been overrun by the barbarians of the North, with that in a later age, when Christian civilization and liberty gave impetus to agriculture and commerce by imparting comparative security to the people who embarked in such industry and advancement The region now called Turkey in Europe, Greece and Asia Minor, exhibits silent but indubitable testimony in support of the same argument

In these days of political struggle and divers interests, in this country, we hear much of the various means for the advancement and protection of the agricultural, the manufacturing, the mercantile, and many others of less extent and importance, including so called *vested rights* Each of these interests is made the theme for animated discussion and sharp contest by opposing parties at the hustings, and thence become irrepressible questions for deliberation and decision by legislative assemblies, both state and national, and correctly so, for where the interests of the people are largely involved it is manifestly the duty of government to foster and protect them, and where they are opposed to each other, so to regulate them on principles of justice as shall conduce to the general welfare and happiness

But what question of a mere business interest can compare, either in importance or extent with the general and individual interest which every man has in the preservation of health and life? No matter what the labor, manual or intellectual, at which he is engaged, nor how productive, each and every mode of obtaining individual supplies and contributing to the social welfare of the community is, and must ever be, subordinate both individually and generally to the possession of health, the cash value of which is well recognized

Accepting the estimate made by statisticians of the financial value of the life of each able-bodied, industrious man at *sixteen hundred dollars*, and the average cash value of each man, woman, and adolescent above twelve years of age, at *one thousand dollars*, we then have some conception of the financial value of the life of each citizen, and the loss to the wealth of the community in unproductive labor from sickness, and by death, from preventable diseases It needs, therefore, no labored argument to prove that it should be the first duty of government, alike state and national, to protect the public health by legal statutes based upon the knowledge which sanitarians have gained by their self-sacrificing and humane industries, and sown broadcast, without price, among the people, and to see that all the members of society are benefited by it Indeed, every measure which relates to the improvement of the sanitary condition of the people generally, deserves the earnest attention of statesmen and the favor and hearty support of the national government Truly, sanitary science investigates the wants of humanity, and holds within its broad scope society in general Human vicissitudes meet it at all times and places, and everywhere they find it prepared to give succor equal to the existing emergency

Statistical researches have discovered two extremely important facts,—namely that the mean duration of human life is generally less than the three score years and ten commonly allotted as the term of man's existence, but that, on the other hand, communities have it in their power to diminish the causes which produce sickness and premature death, and it has been made evident that in consequence of the wise employment of that power, during the last century, the average duration of human life is slowly but progressively on the increase

A comparison of the liberal and wise provision made by some of the European powers for the promotion of sanitary science, and for enforcing its life-saving and wealth-producing precepts among all classes of the people, with the spasmodic, unreliable and inefficient legislation on the same subject in this rich and great country of ours, is, to say the least, not flattering to our national pride Yet, withal, it must be acknowledged that the national legislature is very liberal in many matters In the exercise of its supreme authority over land and sea, it is not only utilitarian, but really scientific and very sympathetic Unfortunately, however, protection of the citizen from preventable diseases which destroy many thousands of lives annually, the cash value of which amounts to millions of dollars, seems to be no part of the national care or responsibility

From the Agricultural Department, the Commissioner may send our distinguished Fellow, Dr Salmon, into any part of the United States to investigate an outbreak of disease among cattle, horses, sheep and swine, chickens, geese and ducks—if there should be no demurrer of *States Rights!*—and he may order an inquiry to be made concerning the blight of the crops—the *potato rot*, for example,—and the best method of housing, making healthy and productive swarms of honey bees, but what special, well organized national department have we which is charged with the humane duty of investigating the causes of diseases among men, women and children?

The national government has been thoughtful and liberal in establishing a Department of Education, and the Commissioner, General Eaton, has so wisely and admirably directed the interests committed to his care that, hand in hand with State Superintendents of the public school system, under his leadership the whole nation has been thoroughly awakened to the importance of the mental culture of the citizen, but, unfortunately, at the same time, greatly to the neglect of his physical culture, without attention to which there can be neither longevity and improvement of race, nor stability of government In other words, the *intellectual life*, not the *absolute life*, is the subject of national concern

There have also been provided a Department of Justice, a Civil Service, and a Secret Service, also many other agencies for the enforcement of law and order in society Even the fisheries, the fish-hatcheries, and the young seals of Alaska must needs have their agents, and are thus vouchsafed national protection, but the defenceless innocents, intended by nature to be the citizens of the next generation, may be killed by hundreds of thousands annually, from preventable diseases—scarlet fever, diphtheria, measles, etc —and the slaughter is wickedly charged to the will of Divine Providence!

The passage from infancy to childhood, and from childhood to adolescence, is a thousand times more dangerous than the approach to our harbors, but no central effort is made to save the children from death before they reach their fifth anniversary in the voyage of life During the present year an appropriation of over two millions of dollars ($2,368,102) was made for the establishment and maintenance of light houses, fog-signals, and other like means to warn and guide the mariner, and should shipwreck nevertheless overtake him, nearly another million ($926,900) has been furnished to aid in his escape from imminent peril by keeping up the service of the Life Saving Stations

In the same spirit, the Signal Corps was supplied with $862,580 for its support It is a valuable service, and well repays to the country the money expended upon it So long, however, as the object of this weather bureau embodied merely an effort to protect the citizen from disease, no money was voted to prosecute the needful inquiries, but as soon as it was suggested that warnings might be given of approaching storms, and *property*, both on land and sea, be thereby protected, money was appropriated by millions to aid and, as far as possible, perfect that service

To the same object may be ascribed the munificence of the government in giving millions of money to the Coast and Geodetic Surveys, and for the work of the engineers in enlarging the channels to our harbors and improving our interior water ways And thus it seems it is less the life than the property of the citizen that is the object of care, for we have seen where property is concerned the national legislature is always appreciative and liberal It is only when we come to ask for help to combat the preventable diseases constantly present among the people, and save thousands of valuable lives, that the minds of the national guardians become unappreciative and inattentive

The liberality in aid of Arctic relief expeditions, and for observations on the transit of Venus, is in striking contrast with the legislation on the subject of the public health In the budget of appropriations for the present year, $146,500 are given to the National Museum, $24,500 for the Howard University, $49,900 for the Freedman's Hospital and Asylum, $242,138 for the Hospital for the Insane, $72,000 for the Columbia Institute for the Deaf and Dumb, and as final aid to the World's Industrial and Cotton Exposition, $335,000, but how much for the protection of the health and lives of the people? It is true, temporary provision has been made to protect the country at large against the exotics, cholera and yellow fever, but it is the enemies we have always with us—scarlet-fever, typhoid fever, diphtheria, and other well known diseases—that produce the greatest destruction of human life and swell the total of the general distress in all parts of the country, and to combat which no national provision has been made.

Besides all this surveillance of various interests, and the supply of millions of money to support them, how many square miles of the national domain have been given away in railroad subsidies under the plea, no doubt, that "the end justifies the means?" Yet these acts of a liberal and progressive government constitute, probably, not the one hundredth part of the sum total of appropriations of money for purposes of far less importance than the interests of the public health

It may be said that protection from the common diseases of the country is a matter that belongs to the State, the municipality, but it belongs to the national government as well, at least, with equal reason for the establishment and maintenance of a central Bureau of Education, and a Department of Justice, that much more can be effected by national work and cooperation than by a series of independent and incoordinated local efforts

But I pray you not to believe that I think the Departments of Agriculture, Education, and Justice have received undue support and encouragement. Very far from such an opinion, so far, indeed, that I should be glad to see increased facilities given to the Agricultural Department for the study of the diseases of our domesticated and food-producing animals; also, greater latitude of authority and more money given to the Department of Education. My object in directing your attention to them is simply to show that the interests of the public health have not received a corresponding and sufficient share of national aid and encouragement.

The National Board of Health, which a few years ago was a live power and a strong arm in protecting the public health, has been so completely handicapped and crippled by inadequate appropriations of money for its support, that it has lately been incapable of performing the important service for which it was created, and, for that reason, has now but a nominal existence.

The Marine Hospital Service has been greatly favored, and having been thus encouraged, its authority has been industriously directed by the Supervising Surgeon, Dr. Hamilton. Indeed, he has done his work so well that there is danger, I think, of overloading him with extra official duties and responsibilities, such as the control of Coast Quarantine and Sanitary Inspections, with their complex entanglements, national and inter state—duties which were not embraced, or so delegated, "in the bond" establishing that service. But however active and efficient this valuable service may have become under the administration of its able director, Dr. Hamilton, it is not proportioned to meet the need of a permanent and well supported National Health Bureau, which humanity, the spirit of the age, and the progress of sanitary science in this country demand shall be established, either as an independent branch of the public service, or in connection with the Departments of Agriculture and Education. Without such national recognition and liberal support, it is impossible to bring sanitation in this country up to the level of its rapid advancement in Europe, and surely this great government of ours ought not be behind the sister governments in such good work.

We are, to day, at the very threshold of great possibilities in preventive medicine, and the central government should foster every effort for the success of the work in which sanitarians are so heartily engaged. To aid them in the study of contagious or infectious diseases, both among human beings and animals, and the blights upon our crops, a National Biological Laboratory should be provided, and no other place would be so well suited for the location of such a school of science as the new building now in process of erection for the Army Medical Museum and Library. With a thoroughly equipped National School of Biology, our scientists would then not have to visit the laboratories abroad—to Pasteur, in Paris, Klein, in London, and Koch, in Berlin,—neither should we see our own distinguished Sternberg quartered at the Johns Hopkins University, in Baltimore, for favorable facilities for the study of micro organisms in relation to diseases.

Biology owes its existence to microscopy, and under its searching penetration the whole field of the practice of medicine has been revolutionized and placed upon more rational foundation. Without the aid of microscopical investigations, sanitary science could have made less substantial progress, and mere conjecture would still be the answer to many of its important problems. Hence, to be a sanitarian in the full sense of the name, means familiarity with microscopical technology, and the ways by which the great advances of to day in science have been reached. Verily, what a speedy march to triumph in the inviting field of Preventive Medicine, if every board of health, every health officer, every practicing physician, were familiar with and employed the microscope in the study of the natural history of diseases? What is wanted is a unification of scientific sanitary work. A civilization based on science is ever progressive, and if our hopes for a glorious future are based on scientific research, they are truly well founded.

I hope you will take advantage of the opportunity afforded by this meeting, to urge upon Congress, now in session, the necessity of legislation in the interests of the public health and scientific sanitary work. Your presence in such large numbers—having come up hither from your far-off homes, quit for the time, your business of bread winning, and emptied your pockets of many hard earned dollars in payment of necessary expenses of the trip to this meeting—is sufficient proof of your earnest, self sacrificing labors in the vineyard of sanitary science, and will, I trust, influence the national legislature to establish on a broad and firm basis a health bureau which shall prove both a blessing and a pride to the whole country.

The pestilence—Asiatic cholera—which has swept off so many thousands of human lives in Europe during the last two years, threatens this country, and, like the awful sword suspended over the head of Damocles, may fall at any moment upon our people and turn the whole nation into mourning. We can scarcely hope to escape next year the presence and terrors of the merciless visitor whose line of march, wherever recorded, has ever been strewn with the dead bodies of its multitude of victims. Are our houses in order for the coming of the unwelcome guest? If not yet, further precious time should not be wasted. In all places the alarm should be repeated, and the command given—"be ye also ready!"

This meeting will be especially memorable because it begins a new series of volumes of the Transactions of the Association. The work done in the past, and recorded in the first series of the handsome volumes, speaks for itself. In none of the great libraries in this country can there be found a system of sanitary literature of greater variety and value than in these volumes. In order that their compass and value may not escape your attention, I have run over them to make and present the following condensed statement of their contents.

Volume I—563 pages—contains 48 papers by 44 authors.

Volume II—552 pages—43 papers by 39 authors.

Volume III—241 pages—29 papers by 29 authors.

Volume IV—396 pages—37 papers by 33 authors
Volume V—256 pages—20 papers by 19 authors
Volume VI—497—pages—36 papers by 36 authors
Volume VII—446 pages—33 papers by 30 authors
Volume VIII—359 pages—21 papers by 20 authors
Volume IX—453 pages—26 papers by 26 authors
Volume X—536 pages—46 papers by 43 authors, or a total of 339 different papers by 222 different authors, not including 12 Presidential addresses and many verbatim reports of interesting discussions of important questions

Several of the earlier volumes have already become so scarce in the office of the Association that the Treasurer, Dr Lindsley, has been lately a purchaser of these issues, as opportunity presented, in order to enable him to furnish complete sets Very soon, the first three volumes cannot be supplied at any price, and the question may now be raised, how shall the break of the set be remedied? The issue of a second edition would be next to impossible, and the only way, I think, to meet the situation would be the publication of a compendium, in one volume, of all the papers contained in the ten volumes I submit this question for your consideration, and should it receive favor, you will, I am sure, have no difficulty in finding "the right man in the right place" as editor of the proposed volume

Our energies have been greatly encouraged during the past year by the munificence of Capt Henry Lomb, a citizen of Rochester, New York, whose large heartedness of sympathy, and pure love of humanity, induced him to offer at the St Louis meeting, last year, the sum of $2,800 in prizes to be awarded at this meeting for the best essays on the four subjects selected for competitive study and report This noble example of Capt Lomb, it is to be hoped, will, from time to time, be followed by other persons of like liberality, and who believe with him that the cultivation of sanitary science is the way to the highest citizenship and a life of moral purity The presentation of the Lomb Prize Essays will, therefore, be a special feature of the proceedings of this meeting How to place them in the hands of the people, and carry out the wish of the generous donor, is a question of great importance and should receive attention, and be disposed of, at this meeting of the Association

Of not less importance to the Association and the general public will be the report of the Special Committee on Disinfectants, and if the character and value of the complete or final paper may be measured by the preliminary reports which have been made by individual members of that committee, and published in the *Medical News* (Philadelphia), it will prove one of the most valuable contributions ever made to the Transactions of the Association No such painstaking labor in this field of research was ever before undertaken in this country, and I predict for it not only the attention, but also the thanks of all English speaking sanitarians These papers will make the next volume of Transactions a book of unusual interest and value

And now a few words to my fair hearers who have honored us by their presence, and I am done The goddess Hygeia—your patron saint—will accept of her admirers and votaries no mere lip service, nothing less, indeed, than supreme devotion to her charms The cause of sanitary science presents a strong claim upon your sympathies and affections, because its saving influence brings to the lying in room, the nursery, the family circle, even down to extreme old age, the beauty of health and the fulfilment of domestic happiness

The elevation of woman, the just appreciation of female excellence, has ever continued to keep pace with the advance of literature and science Look at her condition among savage tribes, cultivating the field, or carrying home the bleeding victim of the chase, driven before her barbarian lord Look at her condition among the semi-barbarians or half-civilized nations, shut up in harems or seraglios, cut off from the enjoyment of society and denied the invigorating influences of pure air and God's own beautiful sunlight But behold, as science advances, she gradually acquires her true position in the scale of social life, the object of universal regard, the inimitable type of the artist's skill, the theme of the poet's happiest inspiration I will not ask you, Ladies, to approve, because I know you *will* approve and applaud the labors which are poured as votive offerings at the shrine of your loveliness

NOTES ON A CASE OF DISEASE OF THE BRAIN[1]

BY H J B WRIGHT, M D,

OF OLNEY ILL

In presenting this case to the Association, I have selected only a few of the many changes of symptoms which it presented I shall purposely omit details, because they do not appear to be necessary to a proper understanding of the structural changes of the case The treatment did not seem to modify the disease, and therefore I shall not introduce it The refusal of near relatives to permit an autopsy in the case, which was obscure from first to last, leads me to assert that *grave robbery* is *sometimes* justifiable

Mr J R M came to my office in August, 1883, asking advice about a small ulcer which was situated on the anterior surface of the middle third of the left leg He was not quite sure, but thought it was caused by a slight blow At first it was a slight node, tender to the touch A few weeks afterwards the skin broke and ulceration commenced At the time of his visit to my office he weighed 180 lbs He asserted that his habits had always been good, he had never had venereal disease For several years his occupation had been buying and shipping horses For several years he has had slight rheumatic pains about his shoulders, and in 1875 had a slight facial paralysis, which rapidly passed away Otherwise his health had always been quite good

Further examinations showed that the ulcer on his leg would permit a probe to sink to the periosteum, and to be one half inch in diameter The skin about the ulcer was bluish and thickened, and the lower third of the leg was slightly œdematous His pulse was 85, but very feeble, and the heart's action was in keeping with the radial pulse His skin was soft and slightly sallow Tongue rather broad, and covered with a muddy coat Temperature 98 5° F He said that his appetite was good, and his bowels active enough, but he felt weak and disposed to sit or lie down I could find no evidence of syphilis

---

[1] Read before the Mississippi Valley Med Association Sept 9 1885

Three days after this, on Aug 31, he was taken with a chill, followed by fever, the temperature only rising to 101° F, but the pulse was 120 He was highly delirious, but would answer questions, and expressed himself as having pain in his head, though he would not locate it There was no disturbance of the stomach, but the bowels were torpid The edges of the ulcer were pouting, and the tissues around it engorged From the ulcer was flowing a thin cream colored, offensive pus During the following night the radial pulse grew less frequent and the temperature gradually abated On the following day he was only slightly delirious, complained of pain in his head and flashes of cold and heat in his back

During the fortnight following, the prominent symptoms were as follows Pulse always weak, easily compressed, and ranging in frequency from 70 to 140 During much of the time it was 90 The heart sounds during much of this period were barely audible, often indistinct The circulation in the extremities was good, the hands and feet being warm The skin was never dry and harsh, but was always sallow,—though never markedly jaundiced His tongue was broad and thick, and coated whitish or cream colored, but was never dry The breath was very offensive, often exceedingly so Stomach quiet, he was indifferent to food, but took nourishment enough The bowels were torpid, but acted under the influence of mild cathartics Abdomen soft, never distended by gas He voided about forty-eight ounces of urine in each twenty four hours, contained no sugar nor albumen, but was heavily loaded with urates and sometimes with phosphates

The condition of the nervous system was of very considerable interest His mind was almost always befogged during the first eight or ten days of this period During these eight or ten days he slept from twelve to eighteen hours each day, and his mind was much like that of a typhoid fever patient During the latter part of this period he often talked of driving over the country to look at horses and mules, of eating his meals at certain houses, and of doing just such things as a man engaged in his occupation would do His sentences were well connected, and he could follow an idea in a straightforward manner So consistent and natural were his vocal expressions, that a stranger would not have noticed his mental aberration But his statements were almost always untrue He would talk about having driven over the prairie to Mr A or B's house, and having bought a horse of a particular quality, the facts being he had not left his room for several days He recognized his friends, though he often forgot their names He was seldom angry, and he never positively refused to follow the directions of his physician, yet he often did so through the obtuseness of his mind Occasionally he had some difficulty in formulating his ideas, which seemed to be the result of his forgetting words He had, during this fortnight, persistent frontal headache of moderate severity, which was made worse by the use of quinine and alcoholic stimulants The brows were often contracted, his face presented a look of weariness, and at times he would stare During eighteen hours he had double vision, but there was no perceptible deviation of the eyes, and the ophthalmoscope showed nothing within the ball to account for this diplopia A slight paretic condition of the muscles of the extremities existed, but there was no well defined paralysis of any muscle The only indication of spasm which manifested itself was a slight hiccough, which returned at short intervals during two days

On Sept 21, we made a crucial incision through the ulcer, and found no disease of the bone, but burrowing pus

Sept 25—My notes read Slept well last night He now has ptosis of left lid, with equal contractions of both pupils, no facial paralysis, protrudes tongue slowly, but in a straight line He cannot express himself so as to be understood, his vocal organs being in a state of paresis Wound on leg granulating nicely

Sept 26—Is semi comatose, pupils contracted, skin covered with cold perspiration, heart beats seventy times a minute, respiration eleven a minute, and largely abdominal Temperature 101° F

Sept 27—Skin warm, heart's action stronger, respirations increased to eighteen and less labored, but it is with difficulty that he can be aroused

On the following day, the parts supplied by the left seventh nerve were all paralyzed, and the frontal headache continued He eats anything offered him, but has no choice, the sense of taste being much impaired Voided urine involuntarily to day

Sept 28—Wanders about his house, removes the covering from his bed, spits out his medicine, talking less coherently, and enunciates more distinctly Cutaneous sensibility unimpaired Sometimes holds his fingers in an awkward position for several minutes

Sept 30—Wanders about his neighborhood examining horses and trying to buy them, and this is done contrary to the earnest protest of his attendants The paralysis is growing less He protrudes tongue in a straight line

Oct 5—Paralysis all gone, pulse quite good, tongue clean, leg much improved Went to barbershop and behaved himself nicely while being shaved When asked the name of the day of the week he is uncertain When I laid my finger on his wrist to examine his pulse he said "I want you to examine me through sea water up and down," and then spoke several words indistinctly Five days after this the condition of his mind was improved, but he hiccoughed for several hours

Oct 20—Has some difficulty in swallowing, mind improving

Nov 12—Can express himself very well on any subject with which he is familiar, such as buying and shipping horses as connected with any particular place, but he is unable to transfer his train of thought correctly from one locality to another. He cannot tell whether he lives in Olney, Ill., or Washington, Ind. It is with great difficulty that he can read small type. There is now a paretic condition of the right side of the face, and upper and lower extremities, and the tendon reflex is more prominent in the right leg.

One month after the above entry, my notes say that his mind is active, but his memory is very poor. For a pain in sacrum I gave him a hypodermatic injection of morphia, which he had entirely forgot ten minutes after. This sacral pain extends around the lower portion of the abdomen, and he has to micturate much too often."

Dec. 27.—Tongue deflects to right. Left corner of mouth slightly drawn up. He talks freely and walks about the neighborhood at his leisure, but the muscles of locomotion are weak.

During the first six months of 1884 his condition was uneventful. On July 30 he slept heavily, and at 9 A.M. was in a stupor so profound that he could not be completely aroused. Early in the day there was marked facial paralysis again, but this passed away against 4 P.M., at which time I saw him. Pulse sixty-four and very feeble, skin cool, face flushed, nothing abnormal about eyes. Protrudes tongue in straight line. His power to enunciate distinctly is only slightly impaired, but he cannot utter a single complete simple sentence. Generally he only speaks the first word and then is unable to recall the other words with which to express himself. It is with great difficulty that he rises from his couch.

Aug. 10—or ten days after the above notes, he came to my office, walking two squares, and I found that his ability to express himself by means of vocal language had returned, and his mind tolerably active. He speaks slowly but distinctly, and repeats what he said a few minutes before, evidently having forgotten. Swings his feet outwards, and strikes his heels against the floor with a thud. He complains of great weakness in his knees, and is inclined to fall backwards.

One month after this the feebleness of his lower extremities had increased so that he could then walk only a few feet, and when the decubitus was dorsal he could not lift his feet off his bed. The facial muscles were not paralyzed, and the pupils were normal. He could read a newspaper about half a minute, when the letters became blurred and his vision completely failed. He rarely expressed a wish, his sensibilities being all obtunded.

Sept. 26, 1884.—He is unable to rise from his bed, and paralysis of his bladder demands the catheter.

Sept. 30.—A little more than one year from the apparent commencement of the disease, he died from failure of the heart. I regret that I was unable to obtain an autopsy.

In reviewing this case, I will call attention to a few points which comprehend the important features of its symptoms and pathology.

1. The family and personal history were good.
2. No evidence of syphilis could be found, and he was the father of several healthy children.
3. He had a painful ulcer on his left leg, which showed no disposition to heal until surgical interference was resorted to.
4. A progressive enfeeblement commenced about the time the ulcer reached an active point in its destructive process.
5. He was then taken with a chill which soon gave way to a temperature of 101° F. After a few hours the temperature returned to normal. During the remainder of his illness his temperature was generally normal, but it was sometimes subnormal and at other times hypernormal.
6. During all his sickness his radial pulse indicated low arterial tension, and the heart's action was very feeble, the sounds being at times inaudible. Though the heart's action was weak, it was not rapid, except when the body-heat was much above normal. The circulation of the blood in the periphery and extremities was generally well maintained. A sudden change from a recumbent to a sitting posture did not increase the action of the heart more than in health. Excepting a few times, the heart's action was regular.
7. The first disturbance of his mind consisted of a busy delirium, which soon gave way to a stupor from which he could not be easily aroused. After a few days his mind regains its wonted activity, but he is unable to limit his mental activity to the real, and deals with the ideal. His accustomed labors are gone over again as he converses with his associates. Memory is seriously impaired, and his respect for truth is apparently entirely lost. One month after his first marked mental disturbance, he is again quite suddenly semi comatose, and has contracted pupils, very weak pulse, and very slow respiration. From this he gradually emerges again, and reaches a degree of mental soundness which enables him to transact considerable business. By this time he could express himself very well on any subject that he is familiar with, for example buying and shipping horses, as connected with any particular place, but he is unable to transfer his train of thought correctly from one locality to another. Before his death he is twice more semi comatose, each time regaining only in part his previous condition. Before death his memory was nil.

8th.—The last and, from the pathologist's standpoint, the most interesting features of the case are the oscillations of the motor nervous system. It is true that from the first there was a paresis of the extremities, which deepened, and so far as the lower extremities were concerned, finally became a paralysis, but not so with other voluntary muscles. One morning he awakens with marked paralysis of the levatores palpebrarum, and paresis of one part of the larynx, implying injury to the left motor oculi, and probably one or both of the pneumogastric nerves. Three days after this he has well marked paralysis of the right side of face. On this day we find then that the *left* motor oculi, the right facial and a pneumogastric nerve are implicated. Thirty days after this the muscles supplied by these nerves have regained to a great degree their irritability, and difficult deglutition appears to disappear after a few days. Two months after this first disappearance of the facial paralysis it appears again, to fade away again to a paretic condition, which is once more deepened by a marked but fleeting paralysis

Three months after this case came under my care he visited, at my suggestion, a very able physician in Cincinnati, Ohio The following extracts from his letter indicate his idea of the case, and explain themselves

Dear Doctor —Mr M has been under my observation since he arrived in this city, until his departure on last evening to pass again under your care The existence of amnesic aphasia is plain enough, but only a variety of that disease It seems to be clear that the Rolandic areas are involved in the left hemisphere, and the posterior aspect of the left third frontal convolution I am inclined to think that the branches of the left middle cerebral artery have become so affected by the *debris* (?) transported from the ulcerous region of the left tibia as to interfere seriously with the blood supply to the cerebral regions referred to, and greatly to impair their function, more especially the supply to the third frontal convolution I think no positive softening has occurred, but rather adventitious deposits in the affected region Respectfully, ——————

About the same date I sent an exact copy of the notes furnished to this physician to an equally prominent neurologist of Chicago, and received the following reply

Dear Doctor —I have read the full and, on the whole, satisfactory history of the case you write about I have no doubt—reasonable doubt—but that you have to deal in your case with a tumor in the left half of the brain, in all probability with consecutive pachy meningitis, localized inflammation of the brain, regional congestions tending to capillary stasis etc Besides tumor, about the only other thing likely to be present is brain abscess Most respectfully, ——————

Similar notes were sent to a very learned physician in Philadelphia The following is an extract from his reply

I have no doubt that the case you describe so carefully is one of syphiloma of the brain No other theory will account for the symptoms It may and will be said that he has not and could not have had the disease, but this form appears after so many years of apparent cure that no mere denial based on the recent experiences of the individual will suffice

Very truly yours, ——————

TREATMENT OF NEOPLASMS OF THE NASO-PHARYNGEAL CAVITY[1]

BY J G CARPENTER, M D,

OF STANFORD KY

A consideration of the treatment of neoplasms of the naso pharyngeal cavity may be appropriately preceded by a report of the following case

D S C, aged 42 years, of good family history, has been afflicted with naso-pharyngeal and aural catarrh since 1879 The subjective symptoms, hawking, tickling in the throat, sensation of a foreign body in the larynx, great inclination to swallow, asthenopia, nasal obstruction, loss of senses of taste, hearing and smell, were well marked Nausea was present all the time to a slight degree, and culminated in vomiting every morning during the effort to remove the tenaceous muco pus There were profound lethargy and dull headache in the frontal region, impairment of the will, intellect and memory, great irritability, involuntarily fell asleep when reading or making a calculation The expression was dull, indifferent and semi-idiotic Suspicion was such a prominent symptom that he doubted the sincerity of his best friends

Objective symptoms were the following The lining of the naso-pharyngeal cavities was very red, highly congested, infiltrated and tumefied, and had two to five blood-vessels to a circle of a half square inch The vault and posterior nares were covered with a dirty yellow tenaceous muco-pus, the Eustachian orifices were greatly hyperæmic, infiltrated and constricted The right half of the vault and posterior naris were occupied by a fibroma, which projected into the right naris, completely obstructing it The membranæ tympaniorum were semi opaque, retracted, and' the external auditory canals dry and desquamative *Hearing in each ear is* $\frac{2}{48}$

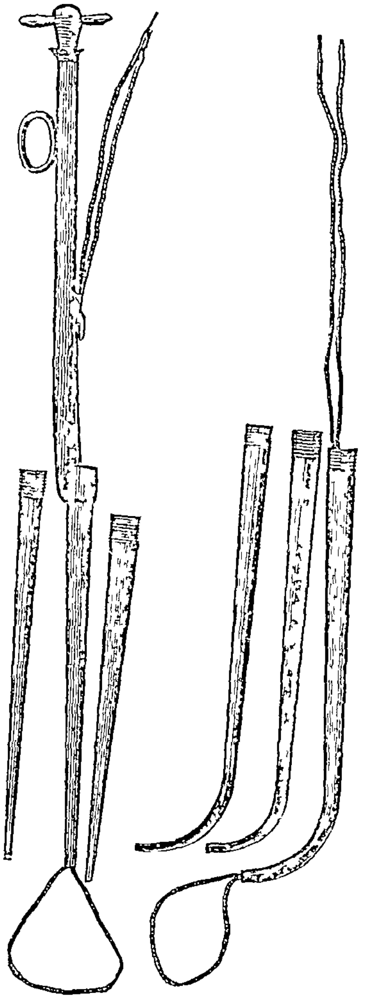
The naso pharyngeal cavities were cleansed with one teaspoonful each of Listerine, glycerine, and chloride of sodium in a pint of warm water, snuffed from a sponge through the nose, with the head in the three positions advised by Rumbold, and followed every day by local applications of oil of eucalyptus, gtts vi, vaseline, ℥i, crude carbolic acid, gr ss, mixed, melted and sprayed with spray producers Nos 1–5, inclusive, for ten days

The catarrhal affection having very materially subsided, an effort was made to remove the fibroid *per orem* with Jarvis's curved snare from the posterior naris The wire was adjusted with some difficulty on account of the growth projecting into the right posterior naris A tape was passed through the right nostril into the mouth, passed around the wire and back into the nostril and out at the anterior naris The wire was thus easily applied by pulling it into the posterior naris with the tape, and pushing it up and back with snare The reflex spasm of the palate was so great that it had to be tied Every time the tumor was constricted by the wire and considerable traction produced by the screw-power the wire would break The snare was discarded and an effort made to remove the fibroid with post nasal forceps, but the attachment was so powerful that it was impossible to do so Further operative procedures were abandoned, and the naso pharyngeal cavities sprayed with oil of eucalyptus and vaseline mixture every day for a week, every other day for two weeks, twice a week for three weeks, and once a week for four weeks, the patient using the Listerine mixture every time before receiving the local treatment, to thoroughly cleanse the parts The fibroid having lost its vitality from the great strangulation of the snare wire and compression of forceps, disintegrated and sloughed without further operative treatment In addition to the local treatment tonics and restoratives were prescribed freely

The use of forceps for the removal of growths of the upper air passages is a procedure in which the mucous membrane, the periosteum, and even the bone are often torn away, the pain and hæmorrhage are often quite severe, and the operator, groping his way and feeling for the tumor, often seizes one of the turbinated bones for the polyp The snare is the most rational, the easiest, most pleasant and least painful of all means for detaching these growths By applying cocaine before using the wire loop, the operation can be performed without pain and irritation to the Schneiderian membrane, and without reflex spasm of the soft palate, or muscles of deglutition, hæmorrhage and destruction of sound tissue are avoided It takes one or more hours to remove a neoplasm, especially if it be a fibroid, with the snare

---

[1] Read before the American Rhinological Association Oct 6 1885



The repeated failure of Jarvis's snare in the writer's hands has caused him to improvise an instrument which has a wide range of application, is much more powerful, and has a different screw power that works easily with the thumb and index finger The screw-power is at the distal end of the snare The instrument is composed of a body and screw, and place for fastening the ends of wire, the wire loop, three straight and three curved tubes of different sizes The calibres of the tubes are traversed by wires of corresponding sizes, if the smallest wire should break a larger tube and wire may be used The straight tubes are used for removing tumors through the anterior nares, or even the uterus, vagina or rectum, the curved ones are for application to, and removal of, tumors from the naso pharyngeal cavity The writer is convinced that two or more strands of copper wire, twisted, are more powerful and remove the tumor more rapidly than the single steel piano wire of Jarvis's snare The wire should always be annealed before using it

Injections of carbolic acid solution, gr x–xxx to ℥i of water into an anterior nasal polypus or hypertrophied turbinated bones has often produced a complete removal of the former and subsidence of the latter, it takes from five to twenty-five injections once or twice a week to accomplish the desired result, and they are quite painful when made to the turbinated bones Mucous polypi and sessile growths of the anterior or posterior end of the inferior turbinated bones have yielded to mild astringent applications with the spray, *pari passu* as the catarrhal inflammation subsided

Polypi have been successfully removed by inserting one index finger into the anterior naris, the other behind the palate into the posterior naris, and thus pinching the pedicle off between the fingers Dr M Rue successfully removed the polypi by passing a cat gut ligature through the affected nostril into the mouth, then tying a soft dry sponge, the bulk of which, when compressed, would just pass through the narrowest part of the nostril, and then making forcible traction, thus removing any growth in front of the sponge

On account of the great elasticity of the soft palate, an antero posterior incision made in the median line, and traction through the opening, has its advocates, for the removal of large neoplasms After the growth is removed, staphylorrhaphy is performed. Hæmorrhage is the great disadvantage of this operation The galvano cautery has proved a very successful means of removing tumors in the upper air passages, as well as in other regions The pain and hæmorrhage are slight, the wire is carried around the growth and tightened, the connection is made with the battery, and the neoplasm burned off and removed The disadvantages of the galvano cautery are troublesome and expensive apparatus, growth often removed by piece-meal, and the process tedious and dreadful to the patient Dr Thudicum removed one tumor in fifty-three pieces, and in another case thirty three introductions were necessary

Langenbeck's operation is performed by making an incision from the inner angle of eye to the angle of mouth, dissecting the flap, and turning the nose to opposite side, thus increasing the space very materially Rouges' operation consists in making an incision from angle of the mouth and jaw upwards, and turning the cheek, nose and lip upon the forehead, and is a more extensive operation than Langenbeck's

Dr Lincoln, of New York, has had great success in using electrolysis by inserting the electrolytic needle into the neoplasm and producing a great reduction in size before the final operation for removal is done.

Sessile growths of the inferior tubinated bones may be removed by passing the wire loop around the posterior end by introducing the index finger into the posterior nares, and holding the wire on the growth while traction is made, and from the anterior nares by passing the wire over the growth, then transfixing it with a needle, and completing the operation.

Wookes recommends the forceps and plow in addition to the wire loop and needle and galvano caustic procedures.

Of all the operations for removing foreign growths from the upper air-passages, the ligature and double canula, and tightening the ligature from day to day, has the fewest advocates. It has the disadvantages of too much time consumed, discomfort to patient and horrible stench, and possible erysipelas and septicæmia.

Hæmorrhage is the great complication to be anticipated in removing fibromata. Cartilaginous and osseous growths may be removed by combining one or more of the above methods with such cutting appliances as saws, especially the revolving saw, and dental engine and drill. Resection of the upper jaw and replacing the part excised after the neoplasm is extracted, has its advocates as a *dernier ressort* to give more space for manipulation of tumor.

If a catarrhal inflammation attends the neoplasm, it should be properly treated, and the lining membrane placed in as healthy a state as possible before the operation; after the operation the naso pharyngeal cavities should be thoroughly cleansed with Listerine, glycerine and common salt mixture, and sprayed with mild, soothing astringent applications.

A CASE OF PHTHISIS WITH NUMEROUS BACILLI; COMPLETE ARREST OF THE DISEASE[1]

BY VINCENT Y. BOWDITCH, M.D.,

OF BOSTON, MASS.

Owing to the universal discussions which have been carried on in the medical world during the past year or two over the bacillus tuberculosis, the following case will, I think, be of interest, and if I present it to you rather in detail, I trust I may be pardoned, as it is for the purpose of seeing, if possible, what deductions can be drawn from it as to the significance of bacilli in the sputa of phthisical patients.

On June 20, 1883, I was called to see Miss H., a young lady aged 23, who gave the following history. Always remarkably strong and well, with the exception of a severe "congestion of the lungs of short duration when a baby." All of the bodily functions had been perfectly regular. The father, mother and the whole family were healthy people, without history of lung trouble in any branch. During the previous winter, the patient had interested herself greatly in photography, and had had one or two severe headaches, which increased in number and severity during the few weeks previous to my visit, and four or five weeks before, a slight hacking cough had begun, with greenish sputa. A rapid and marked loss of appetite, flesh and strength, together with feverishness, occasional night sweats, and increasing languor, after a visit to the seashore, so alarmed her mother that she felt a physician must be summoned immediately.

The patient was tall, of fine physique, the face somewhat pale, with a languid expression, the whole appearance being that of one accustomed to robust health, but temporarily indisposed. The voice was slightly hoarse. Upon physical examination, I found very marked dulness at the right apex above and below the clavicle, extending down to about the second intercostal space, and auscultation revealed very numerous loud, moist mucous râles, with prolonged expiratory murmur and decided "nearness of voice" in the region of dulness. Once or twice there was a suspicion of a "squeak" in the left apex. Elsewhere in the chest the physical signs were normal. The temperature was 100.2°, and the pulse 94.

Nourishment was ordered in the form of milk, to be given every two hours with Murdock's Food, and the patient was told to take Fellows' Syrup of the Hypophosphites, to paint over the region of dulness with tincture of iodine for several weeks, and to inhale once or twice a day a mixture of equal parts of tincture of opium, tincture of hyoscyamus and tincture of conium, the inhaler to be placed in a bowl of hot water.

On June 26, a consultation was held with Dr. H. I. Bowditch, and, upon examination, dulness, moist râles and bronchial breathing were noticed above and below the right clavicle, the râles being not quite so numerous as before. Temperature and pulse were normal. The patient was able to eat more, felt stronger and coughed less. The sputa were nummulated, greenish, and once or twice during the week had had a reddish tinge.

June 27. Sputa examined by Dr. W. W. Gannett, who reported that *the specimen contained numerous bacilli.*

June 30. Examination showed that the signs were certainly less marked but still distinct in the right apex, and the patient reported "no headache for two weeks." I prescribed, as a residence for the summer, Bethlehem, N. H., having refused to allow the family to go to the seashore, as proposed, and ordered the same medicines to be continued, with instructions that the patient should be in the open air every moment possible during the day, to be back by sunset at the hotel and never to remain outside the house after eight P. M., to take no long fatiguing excursions, and to eat all the nourishing food possible.

One month later, the mother of the patient wrote that her daughter's health had steadily improved from the first day of their arrival, and that she was beginning to take active exercise without the slightest fatigue. The patient, however, complained of a slight pain in the right side near the axilla. The cough had nearly disappeared; the menses had appeared within a day or two of the normal time, and improvement was so marked that all medication except painting the chest with iodine had been discontinued. I recommended a simple liniment to be rubbed on the chest over the seat of pain, and ordered the hypophosphites to be continued.

Three months later the mother again wrote enthusiastically of her daughter's gain. The patient had gained seven pounds in six weeks, played lawn tennis and took long walks without the slightest fatigue, slept all night like a child, and only had a slight "hemming" through the day. The record of the morning and evening temperature for five days at this time showed it to be normal, the pain in the chest had ceased and the patient looked "the picture of health"

---

[1] Read before the Section for Clinical Medicine, Pathology and Hygiene of the Suffolk District Medical Society, November 11, 1885.

In spite of the continued favorable reports, I felt skeptical as to the permanent restoration of health, and felt it to be probably but a temporary gain, to be followed soon by a renewal of the symptoms

About the middle of September, after a stay of two and a half months in Bethlehem, the family returned to Boston for a few days, en route for Texas, a part of the country I should not have selected as a winter resort, but which for various urgent reasons seemed the best place for the patient, whom I would not allow to remain in Boston for the winter

Upon examination, the general appearance was of excellent health, the patient being much stouter than in the early summer

A slight huskiness of the voice was noticeable, however, and an occasional clearing of the throat and slight cough after laughing were enough to strengthen my suspicions that there was still trouble left No sputa could be obtained at any time for examination The patient complained of occasional slight "stitches" in the chest, but no localized pain, and felt perfectly well

Physical examination showed dulness still present in the right apex Râles of a finer, drier quality, and much fewer in number than before, were heard in this region and the coarser râles had disappeared The expiratory murmur was marked, with slight bronchophony Respiration in the left apex normal Pulse 68, temperature 97 8° During the stay of a few days in Boston, as the patient's appetite failed and the slight cough increased, I hastened her departure as much as possible

For the next eight months, which were spent in various parts of Texas, I continued to receive enthusiastic accounts of the daughter's health from both parents, with one exception, when, having been subjected late in the winter to very heavy fogs in Galveston, the patient complained of a great sense of oppression in the chest, and of general debility, symptoms which speedily disappeared upon her going to San Antonio, where she remained until the following spring, the early part of the winter having been spent in the interior of the State, where, in spite of great household discomforts and exposure to the blasts of the so called "Northers," icy winds, which suddenly rush over that region in winter, she remained perfectly well, while other members of her family suffered with severe colds and coughs A slight clearing of the throat was occasionally noticed, but so slight that her mother remarked that had it not been for the previous summer's experience, a second thought would never have been given it, and was no more than had been present at times ever since childhood, and the patient weighed more than ever in her life before, namely, 155 pounds

On May 19, 1884, nearly one year after my first examination, the patient returned by sea to New York and thence to Boston, where she arrived with a heavy cold taken in New York during a violent rain storm Headache, with a return of slight pain occasionally noticed in the upper right chest, were also present, but in a few days all these symptoms disappeared

Examination showed upon inspection a slight hollow under the right clavicle Dulness noticed as before The respiratory murmur was less pure than on the left, but it was almost impossible to get any definite râle, even after cough, but occasionally an indistinct "click" could be heard Voice rather nearer than on left Temperature 99°

The patient remained in Boston until the last of June and then went, at my recommendation, to spend the summer near Lake Champlain and in the Adirondack region, a spot which had seemed to me peculiarly suited for such a case Here she remained by my advice, in spite of the adverse criticism of many of her friends, who insisted upon her absolute health, until the following spring, and then returned to Boston the picture of robust health, and declaring that, with the exception of an occasional neuralgic headache, she felt absolutely well, that the pains in the chest had disappeared, that long walks and rough climbing caused no shortness of breath but merely a healthy fatigue, in short, giving a description of as perfect health as one could desire All medication had been given up several months before

Examination of the chest showed a return to its normal color, the hollow under the right clavicle having disappeared The percussion note revealed little difference between the two sides, although at the upper right there was still very slight dulness and a feeling of inelasticity was marked The respiratory murmur in this region was rather harsh and after a slight cough under the right clavicle a faint "crackle" was occasionally heard, but the moist coarse râles heard in the examination of two years before had entirely disappeared, while the "nearness of voice" at the upper right was not quite so marked as before

Considering it wiser for the moral effect upon the patient that she should be told, at the end of my examination, of her recovery, and thus be relieved from the depressing effect of a constant watch upon her symptoms, I bade her, although recognizing in my own mind the possibility of a renewal of the morbid process in the future, to forget that she had ever needed a physician, merely cautioning her against foolishly exposing herself in any way in the future Up to the present time I have had no reason to think my advice unwise, and in my occasional interviews with the patient during the past few months, I have watched in vain for any symptom, apart from those to be noticed only in a physical examination, which to the medical eye and ear would suggest anything other than a condition of perfect health

We have, then, the history of a young lady, previously strong and well, seized with sudden and alarming symptoms of acute tubercular disease in the apex of one lung, followed in a few months by a cessation or "drying up," as it were of the morbid process and consequent shrinking of the lung substance in the affected region, and, so far as outward appearances are concerned, a complete renewal of the patient's health

What have we to learn from this case?

Two facts of marked importance, it seems to me *first*, that the rapidity of the fatal result in phthisical cases is not *always*, as thought by some, in direct ratio to the number of bacilli found in the sputa, (that is, the greater the number of bacilli, the more rapid the course of the disease), and *second*, that the presence of even numerous bacilli in phthisical sputa is not inconsistent with complete arrest of the morbid process and subsequent renewal of the patient's health

One case like the above, as proof of these assertions, is, of course, of great value to us in making our prognosis, in similar instances when, following the teachings of those whose opinions we respect, we are led to give the gravest prognosis and feel no hope for the recovery of the patient whose sputa reveal the presence of the bacillus tuberculosis

In an article entitled "The Pathological and Practical Relations of the Doctrine of the Bacillus Tuberculosis," printed in the *Philadelphia Medical News* of January 19, 1884, Prof Austin Flint writes "So far as my experience goes, an abundance of bacilli in the sputa of phthisical patients is evidence of active progress of the disease and vice versa," and in a conversation with him last spring, he stated that although unable to say absolutely that he had ever so expressed himself in writing, his decided impression was that the presence of bacilli in large quantities in phthisical sputa was a sign of a rapidly fatal termination of the disease, an opinion which, coming from such a source, we are bound to respect, and which make the case in question of still greater importance

I have used the term "complete arrest of the disease," rather than the word "recovery," in this case to satisfy those who with justice claim that we have no right to use the latter term unless the part affected shall have resumed its normal condition The use of the former term, however, is justifiable inasmuch as it does not preclude the possibility of a renewal of the trouble at some future time

MEDICAL PROGRESS

MATERIA MEDICA AND THERAPEUTICS

ROASTED COFFEE AS AN ANTISEPTIC—DR OPPLER highly recommends roasted coffee as a dressing for wounds, and his results from its use are very satisfactory The effect is attributed to the presence of vegetable charcoal and to the aromatic empyreumatic compounds formed during the roasting process Oppler states also that it destroys the odor of iodoform, 20 to 50 per cent being effectual for this purpose He gives the following formula for dressings

Iodoform	50 parts
Finely powdered roasted coffee	25 "

Triturate with a few drops of ether and dry

Iodoform	grm	1 00
Paraffine	"	10 00
Powdered roasted coffee	"	30

It is also excellent for disguising the taste of castor oil

Castor oil		2 parts
Powdered sugar		
Powdered roasted coffee	aa	1 part

Nouveaux Remedes, Oct 15, 1885

CHLORIDE OF METHYL IN NEURALGIA—DR C VINAY, in the *Lyon Medical*, July 12, 1885, writes very encouragingly of the benefits of this drug in neuralgia It was introduced into practice by M Debove only last August, and is very simple in its mode of application, rendered liquid artificially, it is placed in a syphon bottle and its discharge is regulated by a key valve, which allows it to be thrown out as a jet and vaporize, which action results in a refrigeration of —23° C (—9 4° F) This jet, thrown against the skin, results in a rapid congelation, a segment of the skin is instantly transformed into a whitish congealed space, which gives to the finger a sensation of woody resistance In time, ten seconds is enough for the forearm, in sciatic neuralgias, where the painful surfaces have considerable area, thirty to thirty-five seconds suffice for it to act over the whole of the territory of distribution of the affected nerve, from the nates to the dorsum of the foot The sensation to the patient is a severe one, and, so say those who have felt both, more painful than the application of fire In every case the local congelation disappears quickly, the white surface gives place to a very transitory anæmia, with a goose-flesh appearance and general anæsthesia, then appears a diffuse redness which persists for quite a time, and is accompanied with hyperæsthesia The painful sensation gradually disappears, and in a few hours is replaced by a sensation of heat which is very superficial, as it results from the congestion of cutaneous vessels When all pain has disappeared there is, in patients affected with sciatica, a certain degree of paresis of the part operated on, that is, a sensation of unaccustomed heaviness, walking no longer produces any painful feelings, but progression is difficult with the affected side Very often, on the next day or day after, there break out some little phlyctenules of vesication, so that, if a second application be necessary from the persistence of the affection, it is wise to wait until all signs of local phlogosis have disappeared, when there is vesication, say about two days, before renewing it

Dr Vinay records twelve cases, viz six neuralgias of the sciatic nerve, two neuralgias of the central nerve, one neuralgia of the crural nerve, and three lumbagos Of these, eleven were cured and one relieved His cases of sciatica were serious, either from intensity of pain, long continuance of the affection, or trophic disturbances, so that with them he had to make two and three applications before reaching a definite and permanent cure The objections to its use are first, the prolonged erythema that ensues, he has seen a case in which it was present four months, but this certainly is not comparable with the indelible pigmentation often left by blisters, secondly, vesication is frequent, but it has no importance in itself, and thirdly, eschars sometimes result, but they are rare and easily avoided They are superficial and do not seem to be of much importance, they should be avoided, however, as they are a cause for the continuance of the pain in the skin, they interfere with walking, they retard a new application, and prevent patients from going about their usual occupations as soon as they might otherwise. In the lower limb these little cutaneous sphacelæ select the superficial portion of the popliteal space and where the flexion of the knee is most active. This can be avoided by operating rapidly and superficially.

MEDICINE.

Hydrobromate of Quinine and Valerianate of Caffeine in Malaria.—Ceredo, after an extensive experience, concludes that hydrobromate of quinine is preferable to the sulphate for the following reasons:

1. It is more active in moderate doses.
2. It acts as a nervous sedative.
3. It arrests vomiting, a very important matter in some cases.
4. It causes favorable modifications in the type of the fever, and lessens the chances of relapse.
5. It is more pleasant to take, does not irritate the intestinal mucous membrane, and causes neither constipation nor diarrhœa.

If it does not diminish the intensity and duration of the febrile paroxysm, it may be given in capsules with valerianate of caffeine, and this combination, given half an hour before the onset of fever, may arrest it. By thus combining the drugs (hydrobromate of quinine, gr. xv, valerianate of caffeine, gr. viii–x) some of the quotidian forms, which are rebellious to large doses of sulphate of quinine, may be cured. The action of these two salts is much greater than of large doses of quinine alone.—*Nouveaux Remedes*, Nov. 15, 1885.

Intestinal Etherization in Cholera.—Dr. Jose Godoy Rico, of Granada, proposes intestinal etherization in the treatment of Asiatic cholera, on the grounds that the cholera bacillus is killed by ether vapor, and that he believes this bacillus to be the cause of the disease. He thinks it entirely probable that the real cause of the disease is to be found in the ptomaines generated by the bacilli. This does not alter the case, however, since the death of the comma bacilli would at once end the formation of the ptomaines.

For the performance of intestinal etherization a 300 gramme flask is provided, containing 200 grammes of sulphuric ether. The flask is tightly closed with a compact cork, which is perforated so as to include two glass tubes, one slightly curved, through which the ether finds exit, and to the extremity of which is attached a rubber tube, about two feet long, to the end of which is attached a rubber catheter to be introduced into the rectum. The other tube, S shaped and open at the end, is the tube of security, and contains a small quantity of mercury to show any excess of tension in the intestine, since the column will readily and rapidly change when the tension becomes at all too great.

The patient is placed on his back, with the legs and thighs flexed. The ether flask is placed in a vessel containing water at 93° F., and the catheter of the exit tube is gently introduced into the rectum as deeply as possible. The rubber catheter should be sufficiently rigid that it will not curl up in the rectum. Hot water is then poured into the vessel in which the flask is situated, and the ether vapor is at once disengaged and flows into the intestine. The first contact of the vapor may occasion a sensation of burning pain, soon replaced by that of heat and abdominal tension, or there may be colic and vomiting, which are calmed by compressing the tube, or the operator may have to withdraw it to allow the patient to evacuate the bowel. The disagreeable are soon followed by agreeable sensations, reaching high up in the epigastric region, and followed by eructations which have an etherial odor (which proves that the ileo cæcal offers no obstacle to the vapor).

To obtain the desired therapeutic effect, the operation should last from ten to fifteen minutes for adults, and five to ten for children. In the first stage of the disease it should be repeated every twelve hours, in the second stage three etherizations, about eight hours apart, will usually suffice, and in the third stage the etherizations should be short, and repeated every hour or half-hour. Morphine may be given hypodermatically to keep the patient as quiet as possible during and after the operation. Of course the usual hygienic and dietetic measures should be strictly carried out. The method is thoroughly endorsed by Dr. Arozarena, lately of Cuba, and now of Granada.—*Crónica Medico Quirurgica de la Habana*, November, 1885.

SURGERY.

Sponge Grafting and Sponge-Dressing.—At a meeting of the Arkhangel Medical Society, Dr. P. A. Pokrovsky made an interesting communication on his experience in the use of sponge as a grafting and dressing material. Having reviewed the literature of the subject, the author describes his method of treating wounds and ulcers by means of sponge. He takes a best officinal Turkish sponge (to be found at any chemist's shop), cuts it into fine slices (about two lines in thickness), washes the latter in a 3 per cent. solution of carbolic acid, and, after carefully squeezing them out, covers with them the whole surface of the wound or ulcer; over the slices oil cloth or wax paper is applied, the whole being fixed, under but slight pressure, by a roller bandage or a handkerchief. When purulent discharge is excessively free, a layer of cotton-wool or a woolen cloth is placed over the oil cloth. In other words the author uses sponge instead of gauze, as a constituent of a warming compress. The slices of sponge (as well as the whole dressing) are changed one, two, or three times daily, according to the profuseness of the suppuration. The sponge dressing, applied in this manner, was employed by the author in four cases of extensive syphilitic ulcers of the thigh, leg, scrotum, and elbow, in eight cases of soft chancrous ulcers of the glans and collum penis, prepuce, scrotum, etc., in one case of chancrous bubo, and in twelve cases of non-syphilitic ulcers of the leg, forearm, shoulder, etc. In several of the cases sponge grafting, after Professor Hamilton's plan, was tried. The results of the author's observations may be summed up thus:

1. Sponge used as a dressing material acts on the

ulcerative process purely mechanically Being porous and endowed with extreme capillarity, it frees the ulcer or wound from purulent discharge, at the same time, it acts as an irritant on the surface of the ulcer Hence it favors an afflux of nutritive material to the ulcer, which presents a necessary condition for the healing process

2 Sponge is an excellent dressing material in all cases of old obstinate ulcers with free purulent discharge Under the sponge dressing, ulcers pretty rapidly cleanse themselves and undergo cicatrisation [Thus, in seven cases of crural ulcers cure ensued, on an average, in twenty six days]

3 The sponge dressing brings about rapid cleansing and healing of soft chancres and chancrous buboes (cure following in about ten days)

4 In syphilitic cases, the sponge dressing gives rise to rapid cicatrisation only after the syphilitic virus has been mitigated by specific treatment, otherwise the application of sponge causes disintegration of tissues

5 Sponge-grafting causes suppuration and retards the healing process [The author's attempts at sponge-grafting had been so unsuccessful, that he altogether dismissed Hamilton's method from the treatment of ulcers in his practice According to his opservations, sponge grafts do not undergo absorption, but are disintegrated and fall away in pieces during irrigation, or in consequence of their being undermined by pus] The ulcer does not heal until the last sponge particle is removed

In conclusion, Dr Pokrovsky points to the extreme cheapness of sponge dressing All the cases of ulcers which were admitted to the local hospital in 1884 were dressed with sponge, the expense of the latter did not exceed four roubles (about eight shillings) —*London Medical Record*, Nov 16, 1885

TREATMENT OF FRACTURE OF THE THIGH IN CHILDREN BY MEANS OF THE "STEADLE SPLINT"—In a note on this subject, MR S WILSON HOPE, of Pentworth, Sussex, says By the steadle splint, or crib-splint, is meant the using a steadle, bedstead, or crib, for the purposes of a splint, namely, for extension and counter extension, and any further appliance for setting, or coaptation, may be omitted, with good results One method of using it which answers very well is this from an ordinary bandage, cut such a length as, when folded in the middle, will reach from the lower ribs of the child beyond the top cross-piece, forming part of the framework upon which the mattress rests, whether it be the framework of an iron bedstead, of a crib, or of an old wooden steadle Take two such lengths, and lay them singly, not doubled, along the sides of the child's chest, and pass round the chest, under the arm pits, and over the bandage-lengths, an ordinary rib roller On bringing upon the outside of the roller the other ends of the bandage-lengths, there is on each side of the chest a loop of bandage, with the rib roller lying in the loop Let the upper and the under portion of bandage be secured separately by thread or safety-pins to the upper edge of the rib roller, and at such points that the under part goes under the shoulder, and the outer part over the shoulder, without dragging Adjust the child's head and pillow, and fasten the bandage lengths to the top cross piece, which forms part of the framework upon which the mattress rests And one has only to raise the feet of the bedstead upon bricks, when the arrangements for counter extension are complete Cover the ankle thickly with wadding, and, having taken a loop length of bandage, long enough to reach from the angle, beyond the bottom cross piece, forming part of framework which supports the mattress, tie the bandage round the ankle, with the knot at the back, above the heel, make extension, and secure to the bottom cross-piece All that remains is to keep the foot in position by means of bandage-lengths passing round the foot, and fastened to the side pieces of the framework, and the thigh is set The main use of such a plan as this is that, in whatever out of-the way house one finds a child with a broken thigh, there also, is the steadle splint

But, besides, the following points might be mentioned in its favor 1 It avoids all the trouble consequent upon perineal bands in children 2 The counter-extending bands over the shoulder check both forward and turning over movements during sleep, as well as when awake 3 In permitting the omission of special setting splints and all bandaging, it adds to the comfort at the time and throughout the treatment —*British Medical Journal*, Nov 21, 1885

NEPHROTOMY FOR TOTAL SUPPRESSION OF URINE —MR CLEMENT LUCAS performed an unique operation in Guy's Hospital on October 29th A woman, from whom he had removed the right kidney for total destruction of its secreting structure by large calculi and hydronephrosis, about four months ago, and who had made a rapid and complete recovery, was suddenly seized with great pain in the left kidney, followed by vomiting headache, and suppression of urine She passed urine last on Sunday morning, October 25th, between 8 and 9 o'clock and from that time till the operation on Thursday afternoon, no urine passed, and vomiting was persistent Her medical attendant, Mr Atkins, of Sutton, correctly interpreting the meaning of her symptoms, placed himself in communication with Mr Lucas, and the patient was brought to London on Wednesday, October 28th It was thought that the effect of diuretics in flushing the kidney might yet be tried whilst the patient was watched These proved of no avail, and on Thursday afternoon, the patient having become drowsy and much weaker, Mr Lucas cut down on the remaining kidney, and removed from the pelvis a conical calculus, measuring seven eighths of an inch by one half in its greater diameters Total suppression had then lasted 102 hours A free flow of urine took place at once through the wound, and the patient was relieved of her vomiting and drowsiness Five days after the operation she was doing well and feeling comfortable Mr Lucas's case of nephrectomy performed on October 20th healed without suppuration or fever The patient sat up for the first time on the eighth day, and is now convalescent —*British Medical Journal*, Nov 7, 1885

COMPARISONS THAT ARE UNPROFITABLE, AND INFERENCES THAT ARE UNJUST

In another part of this JOURNAL will be found the interesting address of DR J E REEVES, of Wheeling, West Virginia, as President of the American Public Health Association While reading it with both pleasure and profit, the following sentence has again reminded us of the paper on "State Medicine" by Dr Frank S Billings, published in this JOURNAL, of September 19, 1885 "A comparison," says Dr Reeves, "of the liberal and wise provision made by some of the European powers for the promotion of sanitary science, and for enforcing its life saving and wealth producing precepts among all classes of the people, with the spasmodic, unreliable, and inefficient legislation on the same subject, in this rich and great country of ours, is, to say the least, not flattering to our national pride" From this and what follows relating to the same subject in the address, the legitimate inference would be that our National Government had done little or nothing to foster sanitary science or to promote the health of our citizens, and consequently the latter must be suffering in comparison with the citizens of some European countries whose more liberal and wise governments *enforce* the life saving precepts of sanitary science among all classes of the people

The address does not tell us which of the European powers are the most liberal and wise in promoting sanitary science, and enforcing its precepts among the people, or we could turn to the department of vital statistics and learn just how much greater had become the *average* duration of human life in such countries than in our own But if the reader will refer back to the paper of Dr Frank S Billings, he will readily find that the governments which have exhibited the greatest *liberality* and *wisdom* in fostering original investigations, developing sanitary science, and enforcing its precepts in the most efficient and enlightened manner, have been the monarchial governments of France and Germany, while the more liberal or less monarchial governments of Great Britain and the United States have done nothing in this direction To use his own emphatic language "There is no such thing as organized State Medicine in Great Britain or in any of her dependencies" Again, "Great Britain has neither a well organized Public Health or Veterinary Police Service" And again, "In the United States, the people of which boast so much about their intelligence and prosperity, there is scarcely any such thing as State Medicine No efficient Boards of Health, no trustworthy milk inspection, no inspection of dairies, etc, etc Not a State in this Union gathers reliable statistics on these vital questions Our Boards of Health are a farce, composed of men the majority of whom have more knowledge of 'ward politics' than of their technical duties" And so on, *ad nauseam*

It is only just to the members of the Section of State Medicine of the American Medical Association, before whom the paper of Dr Billings was read, to state that its sentiments were freely criticised by several of the members present, and perhaps not fully endorsed by any It is not our purpose, however, to criticise at present either the address of Dr Reeves or the paper of Dr Billings, but rather to use them as suggestive of three very prevalent and important errors The first is the habit, on the part of many of the members of our profession, of writing and speaking in terms of indiscriminate disparagement of everything pertaining to the professional and scientific institutions of our own country, as compared with those of Europe The indulgence of this habit contributes much towards the creation of an unjustly low estimate of all our institutions by the educated classes of other countries, and it strongly discourages efforts at advancement at home Such writers create the impression in the minds of thousands at home and abroad that there are literally no laboratories, either chemical, histological, physiological or pathological, in any of the medical institutions of this country, in which important practical and original work is or can be done The truth is, however, that such laboratories have existed for years in the Medical Departments of Harvard, of the Pennsylvania University, of the Michigan University, of the Northwestern University, not to mention the Carnegie and Johns Hopkins laboratories recently opened, in which the thorough practical education of students is prosecuted systematically, and some original work of value is being done every year And much more would have been done, had not the indiscriminate disparagements of our own writers created the impression among a large part of our young men, that they can not be quite sure they can see, even an *os uteri* through a speculum correctly, unless they do it in Vienna or Berlin If one half the time and money now spent by young Americans in crowding the laboratories and clinics of Europe, was spent in attendance on the clinics and laboratories already established in our own country, that very patronage would speedily bring to them every appliance and facility for education and original research that is to be found in any part of the world

The second erroneous impression created by the writers to whom we have been alluding is, that the United States Government has done nothing to foster medical education or to promote sanitary science To show the erroneousness of such impression it is only necessary to point to the Army Medical Museum and Library, the invaluable volumes containing the Medical and Surgical History of the War, the Naval Bureau of Hygiene, the Medical or Veterinary Department of the Agricultural Bureau, the important original work done in various directions by the National Board of Health and published in its Bulletins, and all supplemented by as efficient a system of quarantine and inspection to prevent the importation of diseases or their causes from other countries, as can be found elsewhere Has not the money been drawn from the Treasury of the general Government for the creation and progressive development of all these? Has not almost the entire work been done by thoroughly trained medical officers of the Army and Navy, liberally detailed from year to year for such work and sustained by their regular salaries from the Treasury? Then why not be ready and careful to give credit where credit is due, instead of indulging in wholesale disparagements?

The third and last error that we notice as fostered by this class of writers consists in the assumption that everything of value in science, medicine and sanitation must be done by the Government With them the citizen is the mere ward of the Government, while the latter is an ideal agency possessed of boundless pecuniary resources and such paternal wisdom as fits it to regulate and provide for all the individual and social interests of man They seem to have no conception of two of the plainest and most important truths of political economy, namely that human governments have no pecuniary resources except what they draw by some form of taxation from the productive industries of the people they govern, and that whatever, of a sanitary, educational, or scientific character, the citizen in his individual, family, or municipal capacity can do, will be done more efficiently and economically in those capacities than can be done by the paternal interference of the Government Hence, while neither Great Britain nor the United States have, in the estimation of such writers as Dr Frank S Billings, "no such thing as organized State Medicine," and "no efficient Boards of Health," both countries are in better sanitary condition to day than any of the larger Continental countries, in both is the annual ratio of deaths to the population less, and in both is the average duration of human life greater Further comment is unnecessary, at present

STROPHANTHUS, A NEW REMEDY OF THE DIGITALIS GROUP

In more than one instance civilized man has turned to good account in the healing of the nations deadliest poisons which his savage brother had employed as an agent of destruction In Central Africa there grows a plant whose seeds are used by the natives as a deadly arrow poison A paste is made from the crushed seeds and with this the arrow-heads are smeared It is a powerful muscle-poison, the same as curare With this agent Dr Thomas R Fraser, Professor of Pharmacology and Materia Medica at Edinburgh, has been experimenting for the last fifteen years or more It is to his paper, delivered before the Section of Pharmacology and Therapeutics at the last annual meeting of the British Medical Association, at Cardiff, that we are indebted for the facts we propose to furnish to our readers

Dr Fraser's valuable contribution, together with the discussion upon it, is to be found in the *British Medical Journal* of Nov 14, 1885 As already stated, the pharmacological and therapeutical properties of strophanthus (hispidus?) have been engaging his attention for fifteen years past, his first contribution on the subject having appeared in the *Proceedings of the Royal Society of Edinburgh*, and the *Journal of Anatomy and Physiology*, 1870 "Previously to this time its chemistry had not been examined, and the only references to its pharmacological action were contained in a brief communication by Pelikan, of St Petersburgh, to the Academy of Sciences at Paris, 1865" In that same year the drug was mentioned in a note to a paper on heart-poisons, by Drs Hilton Fagge and Stevenson In 1872 Polaillon and Carville contributed to the *Archives de Physiologie* the results of their investigations of strophanthus, and confirmed the facts previously announced by Fraser. Its chemical properties were described in 1877 by MM. Hardy and Gallois, in the *Journal de Pharmacie et de Chimie*.

For some time Dr. Fraser was able to obtain but a limited supply of the seeds, and, indeed, for several years was forced to abandon his investigations altogether on this account. He was the first to isolate the active principle which he named strophanthin. This is not an alkaloid, is crystaline white, of a bitter taste, readily soluble in water and rectified spirits, but not in ether and chloroform, and of a slightly acid reaction. It is readily freed from its impurities. Indeed this active principle is so readily separated and exists in such large proportion in the seeds (8–10 per cent.), that so soon as a sufficient quantity of the seeds can be obtained, strophanthin ought to be placed at the disposal of every practitioner. As already stated this agent is a powerful paralysant of all striped muscles.

In order to test its action upon the heart and compare its pharmacological effects with those of digitalis, Dr. Fraser prepared two solutions of the drugs of equal strengths, and by means of Williams' apparatus introduced them into a separated frog's heart. The digitalis used was presumably of fair average strength, having been obtained from a reliable drug-house, yet a solution of 1 part in 4000 failed to paralyze the heart, at least within two hours. On the other hand, solutions of strophanthin of all strengths up to 1 part in 10,000,000 caused a speedy arrest of the heart in systole. Its action was identical in kind with that of digitalis, but inconceivably more energetic. Next a 1 in 20,000 solution of digitalis was made to flow through the vessels of a frog whose central nervous system had been destroyed. In six or seven minutes the vessels became so contracted as to no longer allow the fluid to flow through them. A similar solution of strophanthin, on the contrary, did not produce any appreciable effect upon the arterioles, and even after its strength had been increased to 1 in 2000 the contraction it occasioned was but temporary.

Herein strophanthus presents a striking contrast to foxglove. This difference will probably make it of great therapeutic value, and superior in the treatment of heart disease to any other member of this group of remedial agents. As justly stated by Dr. Fraser, digitalis may not only fail to benefit in some cases of weak hearts, but may actually do harm. It slows and strengthens ventricular contractions, to be sure, but by diminishing the calibre of the vessels, it increases peripheral resistance and thus adds to the heart's labors. Indeed, under such circumstances a heart with degenerated walls may even be subjected to the risk of a rupture. On the contrary, an agent which invigorates the cardiac contractions without materially increasing arterial tension, would seem to represent the purest type of a heart tonic. As a diuretic strophanthus may be inferior to digitalis, since it increases blood pressure only through augmented action of the heart, and not by a heightened arterial tension within the kidney.

Having satisfied himself concerning its physiological action, Dr. Fraser next tried the therapeutic power of this new agent. He employed solutions of the active principle and a tincture of the seeds of the same strength as the tincture of digitalis B. P. Before the Association he narrated the history and displayed the sphygmographic tracings of five cases of mitral disease, in which the remedy had been exhibited in moderate doses two or three times daily. The pulse tracing showed the influence of the agent in forty minutes, and the effects were remarkably persistent. When hypodermic injections of one fiftieth of a grain were given the beneficial action was manifested in twenty minutes. In one case, the pulse fell in one hour and forty minutes from 140 to 86 beats in the minute. The effects did not wholly disappear until the eighth day subsequently. Digitalin, tried in the same manner and of the same strength, yielded less satisfactory results. Prompt and free diuresis always followed the exhibition of strophanthin. There was noticed a slight lowering of the temperature in some cases. The remedy was administered cautiously, it is true, but bad consequences or disadvantages of any kind were not noted.

Space forbids so explicit an account of these cases as their interest would dictate, and the reader is referred for particulars to the original. On the whole, the report of strophanthin is most encouraging, and it bids fair to prove a powerful rival to the representative of this group of heart tonics. We trust that our enterprising chemists will, before long, supply the profession with reliable preparations of it in abundance. All honor to Dr. Fraser for his painstaking and scientifically accurate investigations.

ORAL AND DENTAL SECTION OF THE NINTH INTERNATIONAL MEDICAL CONGRESS.

So far as we have observed, the journals in different parts of the country devoted to the interests of oral and dental science and practice, give expressions of cordial approval of the present preliminary organization of the Congress, and especially of the organization of the Section of Oral and Dental Surgery The only exception we have noticed is that of the *Independent Practitioner*, published at Buffalo, whose editor, in the December number, has the following singular statement "Following this (the meeting of the Committee on Organization, in Chicago, in June last) came the announcement that the Section of Dental and Oral Surgery was, by the reorganized Committee, abolished, and that dentists would not be welcomed to the Congress, upon the ground that such medical men as had devoted their lives to the consideration of diseases of the oral cavity were not engaged in the legitimate practice of any branch of the healing art"

It is a sufficient answer to all this, to simply state the fact that no such announcement was ever authorized by the "reorganized Committee," nor by any other party representing the American Medical Association On the contrary the latter body had fully recognized the relations of dental and oral surgery to the general field of medicine and surgery several years since by organizing and maintaining a Section in that department on the same level with all its other Sections The simple facts are that the Committee of Arrangements at its first meeting in June found nineteen Sections organized, which it was then thought was a greater number than could be accommodated with convenient rooms in Washington, and more than had been provided for at any of the preceding Congresses Solely for the purpose of reducing the number, propositions were made and temporarily adopted to discontinue the Sections of Mental and Nervous Diseases, of Gynecology, and of Dental and Oral Surgery, leaving the workers in those departments to take their places in the Sections of General Medicine, Obstetrics, and General Surgery, respectively We say temporarily adopted, because neither the revision of the Rules nor of the Sections was completed and finally adopted by the Committee until its second meeting, in September, when, after more full consideration, all the three Sections, the discontinuance of which had been proposed, were retained without a dissenting vote in the Committee, that of Dental and Oral Surgery without the change of a single officer And there is every indication that the Section will be sustained with a degree of enthusiasm that will not only do credit to the many scientific workers in that department, but will also aid much in restoring that department to its proper place, as a legitimate branch of the healing art, much to the benefit of both specialists and general practitioners, and it is to be hoped that this Section will be made so eminently successful that no Congress hereafter will be considered complete without it, for we agree fully with the renowned Virchow, that no one department can be isolated altogether without detriment to the whole

A CHICAGO POLYCLINIC

Initiatory steps have been taken to establish a regular Polyclinic in this city, similar in character to the institutions under the same name in New York, Philadelphia, and some of the foreign cities If such institutions are profitable both for those engaged in them and for the profession at large, there is no reason why one of the first class should not exist in Chicago The number and extent of her public hospitals and dispensaries open for clinical instruction, the number and ability of those practising and teaching in special departments, and the number of medical students annually attending her medical colleges, give her rank among the most prominent medical centres in this country

Indeed, there is nothing to prevent any practitioner of more than three years' standing from matriculating in one or more of the regular schools, and by taking the tickets for admission to the principal hospitals and the special tickets for the chemical, histological and pathological laboratories, and then selecting for himself, not only clinical instruction in any variety and to any extent that his time will permit him to attend, but also, in the several laboratories, any amount of practical work either in chemistry or microscopy that he may desire, thereby making up for himself a polyclinic of such extent and duration as he might choose Any thoughtful practitioner can thus select for himself such extent of post graduate studies, in connection with the colleges, hospitals and laboratories of Chicago, or any of the other prominent medical centres of our country, as will be of more practical value to him, than he can get by the expenditure of the same amount of time and money in Vienna, Paris or Berlin He may not acquire as much self conceit, but he will gain a better knowledge of the advantages afforded by the institutions of his own country

THE MUTTER LECTURES —The Mutter Lectures for the present year, at the College of Physicians of Philadelphia, will be given by DR HENRY F FORMAD, commencing on Tuesday evening, December 8, and continuing each Tuesday and Friday evening to January 19, 1886 The subjects discussed in the Lectures will be, "Morbid States as influenced by Embryonal Development, Anomalous Structural Peculiarities, Injuries, and the effects of Lower Organisms, with special reference to *Surgical Pathology*"

SOCIETY PROCEEDINGS

MASSACHUSETTS MEDICAL SOCIETY—SUFFOLK DISTRICT

SECTION FOR CLINICAL MEDICINE, PATHOLOGY AND HYGIENE

ALBERT N BLODGETT, SECRETARY

Meeting of November 11, 1885

FREDERICK I KNIGHT, M D, IN THE CHAIR

DR S C MARTIN, of Roxbury, read a paper on THE INOCULATION, PROPAGATION, AND PRESERVATION OF THE VIRUS OF ANIMAL VACCINE WITH A DESCRIPTION OF THE APPEARANCES OF KINE POX, AND DEMONSTRATION OF THE VACCINE VESICLE UPON HEIFERS

Before entering upon the more practical part of his remarks, he said It is important to define just what true animal vaccination is I know of no better definition than that by my father "The inoculation of a young selected animal of the bovine species from an original spontaneous case of cow-pox, from this, others and so on, in continous and endless series, as the source and the only source of virus for the protection of the human race against variolus disease" This alone is true animal vaccination Retro vaccination, or the inoculation of animals with humanized virus, is an entirely different matter and has nothing to recommend it

A few words in regard to some of the various stocks of cow pox On March 28, 1866, the famous case at Beaugençy, France, was discovered From virus derived from inoculation from this, Professor Depaul continued the propagation of animal virus at Paris, under the auspices of the Academy of Medicine This was the stock introduced into this country by my father in 1870 Various other cases of spontaneous cow pox have been discovered from time to time in Europe, with virus from which animal vaccination has been and is still carried on in a number of establishments, notably at Brussels, Amsterdam, Rotterdam and the Hague After the first experimental inoculation of two calves, animal vaccination was not carried on at Beaugençy, but was immediately transferred to Paris, and to that city the practice of the method in France was confined A knowledge of this fact may, perhaps, in the future prevent a repetition of the ludicrous mistakes which we occasionally see in print, that various individuals have from time to time imported animal virus into this country from Beaugençy When in Paris in 1873, my father was assured by Professor Depaul that the Beaugençy virus, sent to him in 1870, was the last which left the city before the siege in that year, and that during the seige, the "stock" was lost The animal virus employed since the Franco Prussian war, is from other stocks, discovered since that of Beaugençy

In February, 1881, a case of suspected cow-pox was reported to this society by Dr E W Cushing, and was immediately referred to my father, who accompanied Dr Cushing to his brother's farm at Cohasset He there found several cows suffering from an eruption on their teats and udders With virus from these, my father and myself inoculated several animals as well as children, obtaining undoubted typical vaccinal effect This stock I have continued uninterruptedly since, and, as far as I know, it is the only authentic case of cow-pox in this country which has been preserved I keep up three different stocks continuously, namely, the Beaugençy, Cohasset, and the Esneaux stock imported from Dr Warlomont, of Brussels, reserving the upper flank of the animal for the Cohasset, the lower flank for the Belgian, and the belly for the Beaugençy, thus keeping the three stocks entirely distinct, and issuing the virus from all indifferently They appear to be all equally typical in appearance and results

It goes without saying that the animal to be vaccinated should be in perfect health and condition This must be preserved by proper sanitary measures not necessary to detail here The animals should be from six to eighteen months old Too young animals are troublesome to care for and manage, and those too old and large are not only difficult to control, but, notably in the case of those which have borne calves, are probably not free from danger of tuberculosis I use bulls and heifers indifferently The animal is secured upon the operating table, portions of the flanks and belly are cleanly shaved, and scarifications are then made in precisely the same manner as in the human subject, not deep, but merely sufficient to produce a slight appearance of serum tinged with blood These I make some three quarters of an inch by half an inch in size and place them at intervals of at least an inch and a half apart The fluid virus taken directly from an animal, in which the disease has matured and lying upon an adjoining table, is then thoroughly rubbed into these scarifications The disease matures at about the seventh day In this, however, experience and careful inspection of the vesicles is necessary to determine the precise time, it depending somewhat on the condition of the animal and climatic influences During the progress of the disease, the animal is but little affected, the temperature rarely rising more than two or three degrees Occasionally in a very fine development of the disease, the animal may lose its appetite for a day or two

The vesicle on being opened, is wiped clean of any blood or pus, and gentle pressure is then applied The fluid contained in the vesicle is of a light amber color, and should have an unctuous, smooth character In animals where the disease is accompanied by excessive action, as shown by much tumefaction of the surrounding tissues, a large amount of thin, almost colorless fluid is poured out, due to an admixture of excessive flow of serum with the virus itself I shall speak of this matter more at length in a moment In some calves, from the finest vesicles it is impossible to obtain lymph without a certain tinge of color, due to the admixture of a minute quantity of blood This, it can be readily seen, is not of the slightest importance in virus taken from the animal It was always my father's custom, and is my own, to use those points most tinged, not only for vaccinating other animals, but also for human vaccination. The sharp end of the ivory points is charged on both sides with the fluid virus as it exudes from the vesicle. When dried, the points are wrapped in cotton in packages of convenient size, then in paper, and finally are hermetically sealed in gutta-percha tissue. This effectually guards against moisture, and if care be taken to keep them cool as well, they will retain their efficacy for a considerable time. I have myself made vaccinations with points so kept for over a year, and have obtained perfectly good and typical results. This, however, is not recommended. Points should be ordered only in small quantities as required, and used within a few days or weeks. In this, and also in all the details of propagation, it is not what may perhaps suffice, but what experience has shown is safe and good beyond peradventure.

As to the form of virus, I recommend nothing but fluid lymph dried upon ivory points, prepared as above described. Crusts are likely to prove inert, and, unless used with the greatest care, may cause very bad results from partial decomposition ensuing after the crust has been moistened. They are apt also to encourage highly undesirable methods, such as inserting the dry, pulverized crust, or portions of the crust itself into punctures, also mixing with water, and allowing the mixture to remain too long exposed to the air. This was one very serious objection to the "solid lymph cones," formerly sold in large quantities, but now, it is believed, no longer in the market. These were composed of crusts and fragments of crusts, powdered, moistened and molded into cone shaped masses. They were not only open to all the objections applying to crusts but the mode of their manufacture rendered them peculiarly liable to dangers evident to any intelligent physician. Storing fluid lymph in glass capillary tubes has been found very unsatisfactory. It was at one time much in vogue, but experience has shown that virus so stored is extremely likely to prove inert, and unless sealed perfectly tight may become decomposed and dangerous. One great merit of points is, *that it is well-nigh* impossible to have serious complications attending their use, if they are charged with pure active lymph in the first instance. They either produce typical vaccinia, or, at the worst, prove inert owing to some accidental cause subsequent to charging. In distributing any form of virus, we must bear in mind that among so large a body of men as compose the medical profession, some will be found who will not use proper care on all occasions, and it is most important to issue only that form with which it is impossible to go wrong.

The propagation of animal virus, and its distribution to physicians, are at present, in several ways, in an unsatisfactory state. The *New York Medical Record*, in its issue of October 24th, 1885, editorially says: "At present in all large centres, bovine virus in vaccinating is largely used, and the steadily increasing demand for this has led to the formation of companies who undertake to cultivate and sell it, with a view primarily, to making money. These companies are not, as a rule, under any official supervision, and are at perfect liberty to disseminate worthless crusts or septic poison among the people. We learn as an illustration that, with a lot of bovine virus recently sent to Montreal, there were one hundred and two trials and one hundred and two failures, while other specimens have produced badly inflamed arms. Here, surely, is a most anomalous condition of things. It is apparent at once that this cultivating and selling of virus should always be under some official supervision. Most States indirectly compel the vaccination of children, and they should in all justice see that this vaccination be made with pure and efficient material. But the public supervision of vaccine companies is not yet carried out as it should be, although it is a measure most imperatively needed for the security of the people."

The distribution of virus to physicians is now largely done through druggists and instrument makers. My father and I have for several years refused to supply virus except directly to physicians, or through the hands of local agents in Boston for the convenience of the profession. We continued this rule until it became evident that physicians would not take the trouble to procure it direct, but preferred to rely on the nearest druggist. This is all wrong. Vaccine virus is not a substance to pass through three or four intermediate hands before reaching the physician. It is peculiarly liable to deterioration, and, furthermore, the physician should know just who propagates the virus he uses. I fear that in many cases he is entirely in the dark as to this. Many propagators do not do business under their own names. Large numbers of "Companies" are advertising widely. Possibly, some of these are regularly incorporated companies and are conducted by competent men, but it is believed that some of them adopt the title merely as a convenient *nom de guerre*, like those of certain "Institutes" composed of a 'Board of Physicians," in whose spacious laboratories skilled chemists and *savans* compound precious elixirs for the relief of noble but erring youths. I wish to emphasize this matter somewhat for the reason *that physicians have become far to careless as too the* source of their vaccine supply. The druggist naturally will sell the virus on which he can make the most profit. Animal virus, properly and honestly propagated, is not cheap. By improper methods it can be produced in immense quantities. The temptation to do this, particularly in times of great demand, is irresistible to men who have no professional reputation to sustain, and who look upon the matter as a 'business or trade."

I have described and shown what I consider the proper method of inoculating the animal and preparing the virus. My father and myself after many experiments, found it to be the best. The number of points which an animal vaccinated in this manner will yield is comparatively small, but I consider that any attempt to increase the yield is fraught with certain dangers. In times of great demand (the time above all when only what is *known* to be the best should be practiced) certain propagators have found this method far too old fashioned and "unbusiness-like" for their views. An animal must be made to yield 15,000 to 20 000 points, or more. To accomplish this the following expedient has been adopted

A full grown cow is usually selected on account of its size. Scarifications from two and one half to three inches in length, by some two to three inches in width are made on the flanks at intervals of about an inch apart. These produce large inflamed surfaces, often coalescing, so that at the end of seven days, one large sore will often occupy the whole escutcheon of the animal. Upon this being opened, an immense flow of *colorless* fluid results, with which points are charged. I state the method to you, and say frankly that I utterly disapprove of it. Such extensive scarifications with the great attendant inflammation must necessarily produce an excessive flow of serum, and it would be a bold man indeed, who would confidently pronounce the resulting fluid free from the products of inflammation. It will readily be seen that such immense sores will yield an almost unlimited supply of this fluid. It seems to me that the practice is fraught with dangers, evident to any intelligent physician. Suppose the only possible trouble to be apprehended from such virus was either failure to produce typical vaccinia, or the production of vaccinia, *plus* a certain amount of inflammatory action, greater or less.

Surely, there being a better way, it should be practiced in preference, even if not so profitable and even if it did not allow the propagator to be so "liberal" to agents and boards of health.

The wholesale propagation and distribution of improperly prepared virus have done infinite harm to the reputation of animal vaccination. My father introduced the method as an improvement on the existing state of things. It *is* an improvement, and a great reform, if properly and honestly carried on, but many reports, a few of which I read to you, tend to show that from certain causes it is capable of becoming the very reverse of a reform.

The Board of Health of Louisiana writes, May 16, 1882. "Failure with bovine points during the present season has been the rule rather than the exception." The Secretary of the State Board of Health of Arkansas writes, April 28, 1882. "The trouble in this State has been not so much from the bad effects derived from bovine virus, but rather, from obtaining no effects at all. Reports have reached me from all parts of the State in regard to the worthless character of much of the bovine virus employed." The Secretary of the Medical Association of Alabama writes, April 30, 1882. "To sum up the whole in brief, the profession here to a man prefer humanized virus to the bovine lymph in any form, and have long since abandoned it." The State Board of Health of Minnesota writes, April 28, 1882. "There has been much complaint in all directions."

Dr. E. L. Griffin, of Fond du Lac, Mich., an intelligent and able propagator of virus, writes, February 8, 1882. "I fully sympathize with your views on what is being done during the boom to supply the demand, and greatly fear that animal vaccination will get a bad set back from the experience of this season." The same gentleman writes, March 6, 1882. "Those infernal 'cones' have done much mischief, I believe in the West. The other day I got a sharp letter from the Secretary of the Board of Health of a neighboring city, upbraiding me on the quality of my virus, saying that it did not give typical developments of pock, but produced enormous sloughs and sore arms, etc., and wished to know what I was going to do about it. Upon inquiry by correspondence, I found that they had been using cones, obtained from a druggist in Chicago, and that the stuff was represented as coming from me."

Dr. D. A. McLean, of Stanton, Mich., writes, May 8, 1882, in regard to his experience with points from the notable vaccine company before referred to, whose virus was propagated by farmers. This virus he obtained through a druggist, supposing it to be that propagated by the gentleman who exposed the fraud, as narrated before. Dr. McLean writes — "The remaining 1400 cases were vaccinated with points obtained from that institution. A large proportion of these cases were very severe, the fever high and very frequently confining them to the house for a week or more. The local manifestations were great swelling, redness, pain, in fact all the symptoms of vaccinia greatly intensified, and frequently resulting in a deep, foul, and very offensive ulcer. These were very slow to heal, in fact, at this date, nearly three months after the vaccination, I am told that some are not healed. In a large number of cases, I am satisfied that no true vaccine pustule was formed, merely a septic sore, and these were the worst cases to heal, and the constitutional disturbances were the greatest. From my experience I am led to believe that the virus was not pure, that is, proper care had not been used in propagating and preparing it, that pus from ordinary suppurating sores had been used to charge the points, or at least had become mixed with the vaccine virus."

Dr. Benj. McCluer, of Dubuque, Iowa, writes, July 7, 1882. "I used one 'cone' during my vaccinations last December and January. I became fearful of them, as also of the points. The vaccinations were so severe in development, such immense ulcerations occurred in apparently healthy children, that I became doubtful in regard to the propriety of vaccination at all. In fact, I lost all confidence in the integrity of the parties dealing in vaccine matter, and felt that they were actually trifling with the health and lives of the community, as well as the character and honor of the profession which was procuring the supply of vaccine matter from them. I do hope that some way may be developed by which in the future the profession may be able to secure pure vaccine."

Dr. John B. Weston, of Chester, Pa., writes, October 6, 1882. "Part of the time I used a cone which came in a metal box with a file. Part of the time I used a crust. My experience with the cone was vexatious in the extreme. Erysipelas was not infrequent, and I am afraid that the fever and disturbance in one case, if not in two, caused a child's death. The sores in most cases were horrible, and many told me that they would rather have variola itself than what they had gone through. It was not due to any carelessness on my part, for I did not use any a second time, or mix one day's filings with another, so I know the fault was not mine."

Dr T S Hopkins, of Thomasville, Ga , writes to the *National Board of Health Bulletin* of March 4, 1882, describing the effects of vaccination with virus in the form of "cones " "The result has been fearful Nearly every one vaccinated has suffered severely from erythema, or erysipelas, the arm swollen from shoulder to wrist, and the point of puncture presenting the appearance of a sloughing ulcer discharging freely sanious pus Many of the cases have been confined to bed with high fever from five to ten days, requiring the constant application of poultices, and the free use of morphia for the relief of pain It (the virus) 'takes' in all cases, regardless of previous vaccination as shown by well pitted mark, and the inflammation begins frequently on the second day Those who have tried it tell me they would much prefer to have small-pox "

I have reports of many more similar groups of cases, but will not prolong my quotations to a tedious length The above are merely selected as being well marked instances, showing clearly the symptoms of septic poisoning in a greater or less degree It will be observed that the above are groups of cases, showing precisely similar symptoms in a large proportion of the persons vaccinated Single isolated cases of even severe complications, the result of accident, or in unsound or sickly subjects, prove nothing, but such instances as given above are unmistakable The vaccinia induced by heifer transmitted virus is characterized by a certain intensity of action which might be startling to one accustomed to seeing only the effects of the enfeebled virus of long humanization, but this intensity is not to be deplored, and is only what is necessary for proper protection against variola It should run a regular course, the vesicle should not break down except through exposure to violence, and, finally, the crust should fall, leaving a healthy, thoroughly healed cicatrix

The complications spoken of above, as well as the woful lack of success, are not due to the *practice*, but to the *malpractice* of animal vaccination With animal virus properly and honestly propagated, the chances of failure or serious complications are exceedingly small Practically the only guarantee which the physician has that the substance on the end of an ivory point is pure virus, or, indeed, that it is vaccine virus at all, is the reputation, skill and honesty of the propagator So long as physicians and boards of health will buy and recommend virus simply because it is cheap and produces a "sore arm," utterly regardless of the source of supply, or whether the propagator is a physician or not, so long may we expect a reckless increase in production, the keenest and most dishonest competition, and such results as I have shown above Animal vaccination is too efficient a safeguard against a loathsome disease, to have its good name injured by ignorance or knavery The remedy is in the hands of physicians They should inform themselves of the source of supply of the virus they use, and if abuses arise, should denounce them fearlessly, and not leave the disagreeable task to persons whose pecuniary interest in the matter renders their motives liable to misconstruction and willful misrepresentation

The discussion was opened by DR S W ABBOTT, Chairman of the Massachusetts State Board of Health, who stated that he had been interested in the subject of vaccination as a protection from small-pox for many years During the late Civil War, the source of the virus obtained for the army was from retro vaccination from the human species to the bovine, and from this source many thousands of soldiers acquired immunity from small pox Dr Abbott entirely agreed with Dr Martin in the necessity of the greatest care to preserve the purity of the bovine virus, and in the importance to the medical profession and to the entire people that the business of propagating vaccine virus should be intrusted only to such persons as are well known, responsible, and honest, besides possessing the necessary medical knowledge required for the safe and scrupulous management of so delicate a pathological process as is that of the vaccine disease in cattle

The virus of vaccine is subject to many dangers even when most carefully produced and most thoroughly protected From the moment the lymph leaves the parent vesicle in which it was formed, it is undergoing a process of deterioration Under some conditions, the best virus may become quite useless as a protection against the ravages of small pox I have known this to be the case in many parts of the United States, and to some persons it has been the cause of a loss of confidence in the utility of vaccination as a prophylactic measure Dr Griffin, who is one of the pioneers of vaccination in the West, has observed the same failure in regard to the protective power in the virus, which he traces to the following causes *First*, the great distance from the source of the virus, which necessarily exposes this delicate material to many undesirable changes of temperature, and to a longer period of time between its production and the time of its use for protective inoculation All virus is exceedingly perishable, and is constantly suffering from the moment it leaves the heifer There is no doubt that ivory points are much to be preferred for the preservation of the virus, as they are smooth, shapely and convenient, and are beyond question the most useful carrier ever employed

The use of crusts resulting from vaccine vesicles, or any portion of the dried scab, should be utterly abolished, and these substances should be entirely discarded in the protective and prophylactic treatment of variolous diseases Many accidents have occurred from their use for purposes of vaccination, and not a few unfortunate complications, such as erysipelas, abscess, sloughing of the skin of the arm, and occasionally, septicaemia and death, have followed the introduction of the scab, or crust, or the so called "cones," or parts of these substances into the human system Of all these materials for inoculation, the "cones," which were formerly more extensively employed than now are undoubtedly the most dangerous, as they were manufactured from scabs, crusts, and other products of the vaccine process, together with the frequent admixture of manure and other forms of filth and decomposition

The proper time for preserving the virus for inoculation is at a period before the crust is formed. After this time, the contents of the vesicle become purulent, and the resulting scab or crust is formed in part at least, of the dried and changed pus of the later stages of the vaccine sore. When a scab is used, the pus is introduced into the system. The results of infection of the system with the products of septic suppuration are too well known and of too grave a character to warrant the employment of a method involving the needless exposure of human beings to the unnecessary perils of so grave and unscientific a procedure under the guise of hygienic protection from a loathsome infective disorder.

The use of capillary glass tubes containing lymph is also to be discouraged, as the fluid contents are very easily decomposed and may be already in a putrid condition when employed for vaccination. The tubes may also contain many foreign germs, which certainly contaminate the virus and may entirely pervert its usefulness. The contents of the tubes is also often diluted with glycerine or some other fluid, sometimes, no doubt, as a means of preserving the virus, but frequently, also, it is to be feared for purposes of fraud in "extending" the virus. Dr. Abbott spoke of the incongruity of terms designating variola in the cow as a "spontaneous" disease. When we ask ourself, "what is a 'spontaneous' disease?" it seems hardly logical to include among such diseases one so highly infectious, so thoroughly marked and so definitely limited as is cow-pox. Is it, indeed, possible that an infectious disease can arise spontaneously?

Dr. Abbott stated that he has seen no less than twenty cases of cow-pox among the cattle belonging to farmers in Massachusetts. The nature of the disease was tested by inoculation of children, in whom it produced sore arms. True vaccination will not "take" on animals which have had this disease during at least two years. Those milking such diseased cows will frequently acquire the disease upon the hand, from contact with the cow's udder. One cow has often proved a source of infection for others of the same herd, by transmission of virus from one to another by means of the hands of the milkers. This has been successfully prevented by the simple precaution of milking the diseased animal after the others. Such cases among domestic cattle have been observed in Lexington, Woburn, Saugus, and some other towns, and were considered both by the farmers and the State Board of Health to be undoubted cases of cow-pox. The production of animal virus is accompanied by much sacrifice of time and money, and much disappointment and vexation, owing to the spasmodic character of the demand for it as a protection against variola. During the times of epidemic small pox, the demand for virus is very large, while in time of absence of the disease, the demand for virus is almost nil. It is therefore highly important that the production of vaccine virus should be in the hands of trustworthy and responsible men, in order to insure the integrity of its propagation in time of peace, as well as the integrity of quality in periods of epidemic small pox.

The medical profession of the United States should recognize the laudable efforts of Dr. Martin to maintain and propagate pure and efficient virus, and support him in his beneficent work as they supported his father before him. Vaccination can be made thorough and protective only by observing accurate methods in its employment. One of the chief disappointments in vaccination is due to the advanced age and consequent deterioration of the virus employed. A complaint was recently made by a physician in a distant part of the State, that the vaccine obtained for use in that town was quite worthless, and produced no appreciable result in any case. Investigation revealed the fact that the physician derived his vaccine from the local druggist, who had obtained a supply some time before from a wholesale drug store in Boston. In this case the virus had passed through several hands before it reached the physician, and much time had elapsed between the charging of the points from the heifer and the vaccination for protection from variola. It would be desirable if all packages were dated so the physician might be sure that the virus was of a recent production. Otherwise the whole process of inoculation as a protection from small pox might be justly described in the words of a distinguished French physician who said, "Vaccination is a deceptive operation performed with hypothetical virus." It may be added, that if due attention were given to the source from which the virus is obtained, and proper care is exercised in the operation of vaccination, there would probably be much less or none at all of the excited sentiment and frequently also open opposition to preventive inoculation for small pox, and anti-vaccination riots would be no longer known.

Dr. J. H. McCollom, City Physician of Boston, stated that he entirely agreed with Dr. Abbott in the importance of employing only the virus procured from well known and honorable sources, as we otherwise have no guarantee of its power as a protective, or of its freedom from foreign and dangerous contamination. Dr. McCollom has used virus procured from Dr. Martin as well as that coming from other sources. He has occasionally seen the virus produce very sore arms but has never observed bad results. He now unqualifiedly recommends bovine virus. Human virus was formerly very generally employed, and this too without any bad results, but the protective power of humanized virus is infinitely less than that of bovine virus. One of the greatest curiosities in vaccination is the influence of the vaccine disease upon true variola. This was recently illustrated in the case of a man who was exposed to small-pox and two days later was vaccinated with cow-pox. The eruption of variola appeared, as did also the vesicle from the vaccination. The two diseases progressed, but the vesicles of small pox *never became pustular*. The entire disease was checked at the vesicular stage. The importance of vaccination after exposure to small-pox is therefore even greater if possible than before exposure to that disease. The virus obtained from the inoculation of young heifers is preferable to that from cows, owing to the liability of the latter to tuberculous disease. In the light of recent studies in tuberculosis it is important to avoid the possibility of infecting the human body with germs of this disease.

Dr S L Abbott asked if it were the experience of the present season that the inoculation with bovine virus is followed by unusually severe results In many cases there is much constitutional disturbance Is it possible that the existence of small-pox at this time provokes an unusual reaction in the system after vaccination?

Dr Martin replied that true animal virus is characterized by a certain intensity of action more than is observed from humanized virus Instead of a mild vesicle at the seventh day, we observe a well marked disease which may last from twenty one to thirty-two days The areola appears at the ninth to tenth day and the fever also appears at that time A crust is formed after the fall of the scab from the original vesicle The process affects the entire thickness of the skin and not simply the epidermis The intensity of the reaction is a valuable indication of the protective power of the virus Indeed the earlier observers of this process judged the success of the inoculation from the degree of fever produced The bovine virus induces a distinct *disease* which protects the animal system from an invasion by small pox, which humanized virus does not The arms of servants and laborers are more sore on account of their occupation which necessitates exposure of the limbs to various insults, as well as to sudden change of temperature, both of which doubtless cause increased severity in the vaccine disease The term "spontaneous" cow pox is certainly a misnomer It is used simply as a convenient expression in cases where the source of infection of the cow cannot be traced "Spontaneous" infective disease is doubtless derived from some tangible source, but it is impossible to discover its origin If Dr Abbott has seen so large a number of cases of genuine cow pox, he has certainly been far luckier than Dr Martin There may be isolated cases, but they are certainly not generally known The only indisputable case now recognized as occurring in this country is the Cohasset case, which has since been propagated by Dr Martin in uninterrupted succession There are many known cases of spurious disease which make the hands of the milkers sore Such cases have long been observed, and were reported by so old an authority as Sir William Jenner himself, but this disease is not cow-pox, nor has it any similarity to the true disease in the way of protection against small-pox

---

MEDICAL SOCIETY OF THE DISTRICT OF COLUMBIA

Stated Meeting, November 11, 1885

WM G PALMER, M D, TEMPORARY CHAIRMAN, IN THE CHAIR

Dr Bermann presented a patient with

A CYSTIC GOITRE

and read the following history of her case

Miss ——, aged 23 years, consulted me about a throat affection which had been troubling her for several years She spoke in an unnatural falsetto tone, and was subject to frequently recurring attacks of aphonia Laryngoscopic examination revealed complete paralysis of the right vocal cord, a condition evidently due to the existence of a cystic enlargement of the thyroid gland, which was principally developed upon the corresponding side of the neck I treated her for some time with the customary remedies, giving iodide of potassium in large doses, combined with iron, as she was chlorotic External application of tincture of iodine was employed, as well as faradization of the larynx

This line of treatment having failed, I resolved to try a method recently recommended by Dr A Weiss, of Meiningen (*Berl klin Woch*, No 2, January 12, 1885) This consists of cauterization of the integument covering the goitre. After three applications of the galvano-cautery, I observed a decided diminution in the size of the goitre, as well as softening of the contents of the cyst I have no doubt but that after a few more applications the goitre will entirely disappear Her voice is improving very much, and there is every reason to believe it will be fully restored after the cause of the trouble will have been removed

In reply to a question from Dr Hagner, Dr Bermann said he did not believe there was any hysterical element in the case

Dr J Ford Thompson read a note on

THE HYPODERMIC USE OF COCAINE

He said that his early experience with cocaine had not given satisfactory results The reason for this, however, was not to be found in the drug, but in the mode of using it He believed that it cannot be relied upon when merely applied externally to mucous surfaces, skin, or other tissues It seems to have its greatest power when applied to the eye and the respiratory tract In other localities it has often failed him He had used it on the male and female urethra prior to an operation, and there was no anæsthetic effect He had sought to use it before closing an enlarged meatus urinarius, but the man suffered as much as if water alone had been applied He endeavored to dilate the urethra of a young lady in order to search the bladder Before doing so he painted the urethra, in fact, filled it, with a solution of cocaine, but without avail He was compelled to give ether He then began to use cocaine hypodermatically (four per cent solution), and was well pleased with his results When it failed, he believed it was his fault in not waiting long enough for the action of the drug He had used it successfully in operating upon internal and external hemorrhoids, in opening abscesses, in operations upon the upper jaw, in circumcisions, in removing splinters and toenails, in lancing a bone felon, in removing a tumor from the neck, and a fatty tumor from the scalp, in restoring the perineum, in aspirating an abdominal tumor in a child, in external urethrotomy, and in many other cases

On November 9, however, he unsuccessfully injected it before using the actual cautery He attributed the failure, though, to his not waiting long enough for the action of the drug A few moments later, the patient complained of numbness in the part, showing, as the doctor thought, that the action of the cocaine was obtained, and if he had waited the patient would not have suffered from the application of the cautery He had used all the other local anæsthetics, such as rhigoline, ether spray ice and salt, but he considered cocaine better than all others He thought it fortunate that we were in the possession of such a valuable local anæsthetic, as he believed there were many cases in which the causation of general anæsthesia was of doubtful propriety He had seen two cases in the past few months where the death of the patient was at least indirectly hastened by the administration of ether, or at any rate the anæsthetic added to the already existing dangerous condition

In reply to a question by Dr King, he said he had noticed a soporific influence of the cocaine upon one patient, and Dr McArdle had told him of an infant's having been twice put to sleep by dropping it into the eye

Dr King thought it would be a good idea to place a ring upon the surface to be cut or punctured, and pour the cocaine into the space thus circumscribed An incision then being made, the cocaine would be absorbed, and the incision could be continued until the required depth was reached In using it hypodermatically he thought the exposed part might escape the anæsthetic effect Moreover, this method might be tried if the doctor had forgotten his hypodermic syringe

LETTER FROM LONDON

(FROM OUR OWN CORRESPONDENT)

Value of Vaccination — A New Ventilator — Pasteur's Work in Hydrophobia—Tauro cholate of Soda in Gouty Obesity and Dyspepsia—Presentation of the Albert Medal to Dr C Thompson—Death of Dr Pirie

Dr Gayton, Medical Superintendent of the North-Western Hospital, and formerly Superintendent of the Homerton Small-pox Hospital, the Hospital Ships "Atlas" and "Endymion," and the Darenth Small pox Camp, has probably had a wider experience in small-pox than any living authority His opinion, therefore, upon the value of vaccination is of the highest importance, and the analysis which he has just published, of 10,403 cases of small pox which have come under his observation, is the largest collection of cases that can be referred to, with the exception of those prepared by the late Dr Mareon, of the Highgate Small pox Hospital In the first place, it lays down that a person who has been properly vaccinated, and re-vaccinated, is absolutely safe Of males vaccinated once, and having good marks of vaccination still visible, there were 1163, the mortality among these was 3 26 Of 922 females similarly marked, the mortality was 2 60 per cent , the combined mortality in males and females being 2 97 per cent Of the male cases in which the marks of vaccination were imperfect—2670 in number—10 11 per cent died, in 2184 females similarly marked, the death rate was 8 46 per cent , the average of males and females together being 9 37 per cent Of 692 males who stated that they had been vaccinated, but whose arms showed no evidence of the fact, the rate of mortality was 29 4 per cent , and among 603 females similarly circumstanced, 24 5 per cent died, the combined mortality being 27 18 per cent Among patients showing perfect marks of vaccination the mortality was but 2 97 per cent Among those whose marks were imperfect the mortality rose to 9 37 per cent , the patients whose marks had entirely disappeared suffering to the extent of 27 18 per cent , while of the unvaccinated no less than 43 70 per cent died More convincing proofs than this of the value and efficacy of vaccination were never published, and one recommends the consideration of the figures to the people who clamor to be allowed to expose their children without this protection to the scourge of small pox

Under the name of the "Gloucester Domestic Ventilator," Mr Ellis, a surgeon of Gloucester, has recently patented a contrivance for the ventilation of rooms, which seems likely to be of great utility It differs only in details from the form of ventilator with horizontal inlet and vertical distributing tube, which was re introduced to public notice a few years ago by Mr Tobin The details in question are, however, of considerable practical importance At the junction of the horizontal and vertical portions there is a door, so arranged that it can close the inlet either entirely or partially, thus giving to the occupants of a room complete control over the quantity of air which is admitted Besides performing this office, the door is made to slide up into the vertical tube, and when thus pushed out of the way, it gives free access to the horizontal portion The outer opening of this is guarded by a strainer of cheese-cloth, or similar material, which excludes dirt, and which can be changed as often as necessary, while on the nearer side of the strainer there is a chamber which can be made to contain perfumes or disinfectants As in the so called Tobin system, the entrance of air is determined by the difference in atmospheric pressure within and without the room, so that the amount admitted will be greater in winter than in summer, and the fire place furnishes a sufficient outlet The ventilator is made by Matthews, of Gloucester, and is of such a size that two bricks must be removed in order to place it in position

The world will owe a lasting debt of gratitude to M Pasteur if he has really discovered how to cure that most horrible of maladies, hydrophobia He believes he has proved it to be curable, and, in support of his assertion he has communicated to the French Academy of Sciences the results of his experiments and researches relating to rabies in the human subject M Pasteur had, in the course of the summer, an opportunity of testing the value of his method on a boy, who had been recently bitten by a dog unquestionably proved to have been mad at the time of the accident The boy had been brought from Alsace by his parents to be placed under the eminent Professor's care He was examined by M Pasteur and two distinguished medical men, fourteen bites were found about his body, and the symptoms of the dreaded disease were already evident in the patient In the space of ten days the child was inoculated no fewer than thirteen times on the same system as M Pasteur has successfully tried with dogs This was three months ago, and until now nothing has occurred in the condition of the patient to shake the operator's faith in his method The boy continues in excellent health, and M Pasteur believes that he is not only safe from hydrophobia caused by the bites of the dog, but also from any bad effects resulting from the animal virus introduced into his system to ensure his safety from rabies

One of the active principles of ox gall has found its way into pharmacy under the auspices of Dr Mortimer Granville, who asserts that he has derived benefit from its use in cases of gouty obesity and dyspepsia The material is tauro cholate of soda, which is prepared by exhausting dried ox-gall with alcohol, and precipitating the tauro cholate by means of ether By evaporation of the ether it slowly separates as a thick treacle like body, which adheres to the sides of the vessel The remaining ether is decanted and the residue dried at a low temperature It is formed into pills, three grains in one pill The taste of tauro-cholate of soda is first sweet and then bitter, it produces in the throat the peculiar sensation of heart-burn It is recommended that the pills be coated with keratine, to prevent them dissolving in the stomach

An interesting ceremony was lately performed at the Castle Dublin, in the presentation of an Albert Medal to Dr C Thompson, of Tyrone Infirmary, in recognition of the heroism shown by him in the practice of his profession, in removing matter which had collected after tracheotomy in a case of diphtheria by sucking it away Colonel Caulfield, of the 4th Royal Enniskillen Fusiliers, having introduced Dr Thompson, the Lord Lieutenant, addressing the doctor, spoke highly of his skill and courage The latter quality, his Lordship observed, had many forms, and the highest form of it was that in which moral qualities mingled with the physical His Lordship added "It is my most satisfactory duty to day, in the name of my Sovereign, to mark you out as one of those who has signally distinguished himself in this respect"

Aberdeen students at home and abroad will hear with regret of the death of Dr D R Pirie, Principal and Vice-Chancellor of the Northern Alma Mater Paralysis was the cause of death The principal was 82 years of age G O M

DOMESTIC CORRESPONDENCE

"PNEUMATIC DIFFERENTIATION"

TO THE EDITOR OF THE JOURNAL

Dear Sir —Having read almost all the articles recently published in this country, on the subject of "Pneumatic Differentiation," as applied to the treatment of thoracic diseases, and having, long since, had some experience with the same *principle* as a therapeutic measure, elsewhere applied to the body, I would offer a few words, which at this juncture may prove salutary—a few lines which may not only be a good thing for the laity (indirectly), but for the profession, directly, as the means of a cash saving, and as a stimulus of thought, in more than one direction It is not my purpose, however, in this article, to controvert any of the positions (though doubting some), assumed by the friends of the "pneumatic cabinet," either as to its efficiency or the *modus operandi* by which its results are achieved On the contrary, it is, in right hands, a good thing My purpose is two fold —to ask of what this new (?) process consists? and how can the "competent" practitioner most readily and economically provide himself and patrons with the same, and at the same time attain or maintain that standard of professional honor, dignity and self respect portrayed by Dr Inglis in his recent address, published in a late number of this JOURNAL?

Let Dr W F Williams, in the *Medical Record*, of Jan 17, 1885, answer our first point "Pneumatic Differentiation," he says, "consists in immersing a patient in a partial vacuum, by removing to a sufficient degree the external pressure of the atmosphere, and at the same time supplying the lungs with air at its normal pressure, and to a greater or less extent impregnated with the substance which it is desired to administer" Very good, that is, analyzed, as set forth in practice, the air in the cabinet is rarefied around the patient sufficiently to, at least, reverse the act of respiration—so that inspiration shall be passive, and respiration active, circumstances governing the degree, and on this very *reversal of normal respiration* hinges the efficacy of the treatment This is the true key to "differentiation" Granted, then, of course, a medicated spray thrown into the denser air will be transported by it towards the less resisting, and elastic lung It will penetrate that lung easier, and to a greater depth, than it would do were the two atmospheres not "differentiated"

We, in the country are very fond of mechanics (necessity being the mother of invention), and certainly the *corpus hominis* affords, at least to physicians, ample suggestions of levers, of triangles, arches, circles, parallelograms of force, of the mechanics of hydrostatics and even of pneumatics, and, most certainly, in the use of the "pneumatic differentiation" process, we are enabled to attain not only the highest state of respiratory gymnastics, but also to most thoroughly apply locally our medicaments And, living 'in this neck of woods," it is very fortunate that Dame Nature has somewhat endowed us with "a mechanical turn," thereby enabling us to answer, incontrovertibly, the second purpose of our communication, viz —to place it in the power of all to provide themselves with the effective means of "pneumatic differentiation'" economically, and without the necessity for, directly or indirectly, partaking of forbidden fruit, and enabling us to live (professionally) as Cæsar would wish his wife to live

Our apparatus (to which all are welcome) may be easily consructed for less than $100 Proceed thus

Make of walnut or other suitable wood an air-tight box or case, 2×8×6 feet. Stand on one end. Fit a plate glass in the front, and back of it hang a good syphon barometer—that any one can make. In the back, opposite to the glass, be sure to construct a door (which you may enter to "correct" your barometer. Ornament to suit taste. Now, hang a second barometer outside of the case. On a stand, placed conveniently, set a tin reservoir that will hold from six to eight gallons of compressed air, which is to be used to atomize your medicated solutions. Next, pass a tube of one inch in diameter through one side of the cabinet, and provide the external end with a flexible tube and mouthpiece, while near the cabinet place a stop cock. Between the flexible tube and the cock, expand the tube and insert a rubber cork of sufficient size to accommodate the nozzle of the atomizer. Last, place a good air pump on the projecting floor of the cabinet, on the same side as the inhaling tube, and provide it with two tubes and so arrange the valves that they may compress the air in the cabinet or in the reservoir, when the pump is operated. These pipes are provided with cocks, so that they may act singly or together.

So much for the apparatus. Now, let us proceed to perform "*pneumatic differentiation*," and thus:

Prepare your inhalant and attach your atomizer to the reservoir, and place its nozzle in the rubber cork. Compare the barometers. Operate the pump till the air in the cabinet is sufficiently condensed, *i. e.*, till the inside barometer shows a rise in the mercury of from eight tenths of an inch to two inches (one inch has not often been used). See that the air in the reservoir is well condensed. Seat your patient in the cozy room, outside the coffin-like box, at the inhaling piece. Now, Dr. Williams's conditions are accomplished, *i. e.*, the patient is "immersed in a partial vacuum"—that is, in an atmosphere rarer than that which he is to respire—rarer by the amount of condensation you have judged expedient to cause in the cabinet. Now, open the cock, let the patient inhale, and the most beautiful mechanical effects—"calisthenic action," corpuscular gyrations and physio-chemico-vital gymnastics, so graphically described by Drs. Williams, Bowditch, Houghton, Smith and Tiegel, will take place.

Your cabinet may be perforated with a hole, surrounded by elastic rubber, through which a paralyzed or atrophied limb may be passed, the rubber serving to bind the member and to exclude the air. Now, reverse the action of the pump, greatly rarefying or exhausting the air in the cabinet. Here, in well selected cases, we will find marked improvement, due to "pneumatic differentiation," by its resultant—a better nutrition. Judiciously applied, this apparatus will not disappoint you. Its cost is far less than that of any device that will do its work equally well, and, paid for once, it will last a lifetime—and, further, in its use no one's rights or interests are violated, and the profession will in no wise become *particeps criminis*, "accessory after the fact," which expression, if somewhat dark, might be elucidated by another, of different profession. And I may close this note with the very last words—words embodying the same sentiments and feelings that thrilled the breast of Dr. Inglis when he uttered them, after having deplored the conduct of the profession in its running after false gods, and pointing them to the resurrection of therapeutics and therapeutists—"Let us all begin now."

Scholium.—A professional brother, just in from Goose Creek (facetiously, I fear), suggests that the cabinet might be made of some other form, and in varied size, adapted to children. I doubt the propriety. Very truly yours,

W. H. Kane King, M. D.

Mt. Sterling, Ill., December 4, 1885.

DEATH-RATE OF PNEUMONIA.

To the Editor of the Journal:

Dear Sir:—Recently the question of the death-rate of pneumonic fever has come up in your Journal. The statements of Dr. Hart (Journal, Oct. 10) regarding the *former frightful* and *now insignificant* mortality attending this disease are but the echo of the words of many other writers everywhere. I have met them over and over again, and have always recognized their harmful nature, and consider your editorial in The Journal of October 31st timely and to the point.

I have collected statistics of 170,692 cases of pneumonic fever, and of these 29,653 died, a mortality of 17.3 per cent. Excluding the 42,467 cases from the German army, with a death-rate of only 3 per cent.—regarding the worth of which I have doubts—and we have 128,225 cases, of which 28,129 were fatal, a death rate of 21.9 per cent. This I regard as being not far from the true proportion. But the important point shown in my tables is the fact that *the mortality varies but little in different lands, or under different plans of treatment, or at various periods of time during the present century.*

Pneumonic fever is, and always has been, the most fatal acute disease with which mankind has had to contend, and we are forced to acknowledge, with regret, that but little has yet been done to diminish its fatality. *It is not now, and never will be, the trifling ailment which it is sometimes represented to be.*

I am, very respectfully,
Edward F. Wells, M. D.

Minster, Ohio, Nov. 21, 1885.

EARLY GONORRHŒA.

To the Editor of the Journal:

Dear Sir:—Dr. E. B. Ward, of Greensboro, Ala., while reporting two cases of gonorrhœa in negro boys, aged 7 and 9 years, respectively, writes: "I would like to ask if any of your readers can report so young a case of gonorrhœa?"

Within a month a lad of *five years* was brought to my office with the following history and symptoms: A neighbor, with whose children the little fellow sometimes played, observed that when attempting to urinate he seemed to be in great agony! She examined him, and at once reported her discovery and suspicions to the child's mother, a widow, of doubtful reputation. The response was, "I know it, but have no money to pay to the doctors."

The Samaritan woman then brought the boy to me In confirmation of my diagnosis of a specific disease, the lad, with downcast eyes, confessed to toying with a dissolute sister of about twice his own age Very truly yours, C M Fenn, M D

San Diego, Cal, Nov 10, 1885

REFLEX CONJUNCTIVITIS

To the Editor of the Journal

Dear Sir—In The Journal of Nov 14, p 538, is an article by Dr N R Gordon on "Chronic Conjunctivitis Dependent upon Diseases of the Intra Nasal Tissues," in which he remarks that no authors have made mention of this fact, and he refers particularly to *reflex conjunctivitis* in association with hypertrophic rhinitis While conjunctivitis by propagation or extension from an inflammation of the nasal tissues is common and familiar to all oculists, the reflected form is *rare*, but in my address in New Orleans (see The Journal, Vol iv, p 705, 1885) I mentioned my observation of *reflex conjunctivitis* as a reflex neurosis of the nose Prior to that time I had never seen it mentioned by any one else Since that time I have seen other cases

Very truly, Jos A White, M D

Richmond, Va, Nov 17, 1885

MISCELLANEOUS

INFORMATION OF IMPORTANCE TO ALL MEMBERS OF THE AMERICAN MEDICAL ASSOCIATION

Membership—Every one who attends an annual meeting of the Association as a delegate pays at that time five dollars, and thenceforward becomes a Permanent Member He continues as such as long as he remains in good standing in the body from which he was originally sent as a delegate As a Permanent Member, he must pay *Five Dollars Annually*, when notified by the Treasurer, whether he attends the meetings of the Association or not Payment of annual dues entitles him to receive the weekly Journal of the Association for one year

Members by Application are such as have not become Permanent Members in the manner above indicated, but apply to the Treasurer for membership, forwarding at the same time to him five dollars and the certificate of the President and Secretary of their State or local society, that they are in good standing in such society They pay five dollars annually thereafter, when notified by the Treasurer Members by application can join the Association at any time, and they receive regularly the weekly Journal

When Dues are Payable—The annual dues from Permanent Members are payable to the Treasurer at the time of the annual meeting of the Association, or immediately thereafter The payment entitles the member to receive the Journal for one year from the following July Payment for 1885, for example, entitles the member to the Journal from July, 1885, to June 1886, inclusive

As some of the members have not yet forwarded to the Treasurer their dues for 1885, they are urgently requested to do so at an early day Having entered upon another year of membership, they are morally and legally responsible to the Association for the payment of their annual dues, having already received for three months of the new year—1885—the Journal of the Association

Subscriptions to the Journal, from those who are not members of the Association, should be forwarded to the office of publication, 65 Randolph Street, Chicago, and not to the Treasurer, but *all payments of annual dues must be forwarded to the Treasurer, Lock Box 1274, Philadelphia*

Deaths—When a member of the Association, who is in regular receipt of the Journal, dies, his family or other representatives are requested to inform the Treasurer at once of the fact

Payment of Dues for Previous Years—As a few members of the Association are still in arrears for payment of dues for 1883 and 1884, they are requested to forward at once to the Treasurer the amounts for which they are indebted to the Association

Transactions of the Association—These annual volumes, thirty three in number, to 1882 inclusive, may still be obtained, with few exceptions, from the Treasurer, at reduced prices The Index to these volumes will be forwarded on receipt of *One Dollar* An opportunity is thus afforded to complete sets of these valuable publications, or to obtain important papers and works which are daily becoming scarce

Richard J Dunglison, M D, *Treasurer*
Lock Box 1274, Philadelphia, Pa

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT U S ARMY FROM NOVEMBER 28, 1885 TO DECEMBER 4 1885

Maj R S Vickery, Surgeon U S A, relieved from the assignment as Acting Medical Director Dept Col, to date the 16th inst (S O 200, Dept Col, Nov 23, 1885)

Capt C K Winne, Asst Surgeon, assigned to duty as post surgeon, Benicia Barracks, and attending surgeon at Benicia Arsenal, Col (S O 109, Dept Col, Nov 20, 1885)

OFFICIAL LIST OF CHANGES IN THE MEDICAL CORPS OF THE U S NAVY DURING THE WEEK ENDING DECEMBER 5 1885

Hampton Aulick, Surgeon, ordered to "Alliance" as relief of Surgeon G P Bradley

Geo P Bradley, Surgeon, ordered to Naval Hospital, Philadelphia

Joseph Shafer, Asst Surgeon, detached from Naval Hospital, Philadelphia, and ordered to "Minnesota"

J H Gaines, P A Surgeon, detached from Naval Hospital, Washington, and ordered to the "Dolphin"

OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF MEDICAL OFFICERS OF THE U S MARINE HOSPITAL SERVICE FOR THE TWO WEEKS ENDED DECEMBER 5 1885

Wyman, Walter, Surgeon, granted leave to attend meeting of American Public Health Association Dec 3, 1885

Benson J, A, Passed Asst Surgeon, granted leave of absence for fifteen days Nov 28, 1885

Armstrong, S T, Passed Asst Surgeon, granted leave of absence for eight days, Nov 30, 1885

Wasdin, Eugene, Asst Surgeon, granted leave of absence for thirty days Nov 28, 1885

Watkins, R B, Asst Surgeon, to proceed to Galveston, Texas, for temporary duty Nov 30 1885

ORIGINAL LECTURES

TUMOR OF THE BACK, LOST DRAINAGE TUBES IN AN ABSCESS CAVITY, CHRONIC SYNOVITIS OF THE LEFT KNEE, FLOATING CARTILAGE OF RIGHT KNEE

A Clinical Lecture Delivered at the Mercy Hospital, Chicago,

BY EDMUND ANDREWS, M D, LL D,
PROFESSOR OF SURGERY IN THE CHICAGO MEDICAL COLLEGE AND SURGEON TO THE MERCY HOSPITAL
(REPORTED BY WESLEY G BAILEY)

Tumor of Back—We may have various tumors of the back, especially in this, the lumbar region As appearances are often deceiving, I will not attempt to say what particular kind of growth this one is It has a small inflamed base, and a whitish point at the extremity Sometimes we have a tumor formed by a diseased sebaceous gland or several of them, and gradually growing larger and filling up with pus and sebaceous material, then bursting, and the abscess for a time, seemingly cured, however, these tumors may burrow into the loose connective tissue This tumor is seen to have a small base, a little *punctum*, also is present

If patients with this class of tumors would have their surgeon attend to the growth occasionally, they could be easily cured by distending the punctum, and pressing out the contents The presence of sebaceous substance in the tumor, clearly defines its character I will now make an incision, working a little slowly, to enucleate the sac In some cases they readily separate from the surrounding tissues, and can be removed without much difficulty, but in this case, it is firmly adherent, and I am obliged to use the knife to dissect out the sac We will preserve some of the blood for chemical examination, to add to our record of blood analyses, as a means of diagnosis, after Freund's method

The interior of this variety of sacs usually presents a "whitish" appearance, indicating its cuticular origin The sac in the case under consideration, however, does not present much of that "whitish" appearance, but looks as if it was an ulceration, presenting only a small remnant of cutis vera These tumors, however long they exist, are not generally supposed to be dangerous to life, though they may cause septicæmia or pyæmia, but I never heard of anyone that lost their life on account of such a tumor In cases of this nature I have known them to contain numerous hairs The sebaceous matter in these sacs, resembles, very much, the vernix caseosa of the new-born These cysts may occur on any part of the body, more especially where the corium is thick This patient comes from Pecatonica, Ills, which place has interested some of you, as a locality of bones of the extinct mastadon, which once ranged in herds in northern Illinois This is not a surgical topic, gentlemen, but as you are lovers of anatomical science, it may interest you to recall here, the fact that the gigantic femur of the animal found there, shaped so much like the same bone in man, presents on its huge globular head no trace of the attachment of a ligamentum teres, it proves that no such ligament existed during the life of the quadruped

2 *Lost Drainage Tubes in Old Abscess*—This patient has been here before, once, six years ago, when I excised the head of the humerus, and once last spring, with an abscess over the scapula He now has a fistulous opening over the lower end of the *scapula* The fistula presents that peculiar granular appearance which is pathognomonic of the existence of either dead bone, or some other inert substance that is foreign to the tissues I cannot by probing detect anything of sufficient diagnostic importance through this small aperture, so we will anæsthetize the patient and enlarge the opening This man has had caries of the head of the humerus and glenoid cavity, and a necrosis of the upper border of the scapula In cases of inflammation of the distal or proximal ends of the long bones of the extremities, you will observe in your practice that those of the upper, recover more readily than those of the lower extremity, the cause being the severe friction and pressure on the synovial surfaces of the latter, which bear the entire weight of the body in walking I will now open the abscess and examine its interior I insert my finger and extract two rubber drainage tubes from the cavity You now see why this abscess would not heal Last spring the patient was here for two days, and went home with drainage tubes in the orifices of the abscess It seems that his wife took charge of the dressing on his return home, and must have lost the tubes into the cavity and left them there I will thoroughly search the cavity for any more drainage tubes, or other foreign articles

There is a pendulous pocket present in the abscess, that I will connect with the larger cavity, further down You will please bear in mind that those exuberant granulations so often present in certain wounds and abscesses, generally indicate the presence of some foreign body in the tissues, it may be bits of clothing, bone, or wood, etc , etc , however, a bullet seems to act differently, the salts of the metal to a certain extent preventing their formation I have now dressed the wound antiseptically, and am certain no stray tubing is left in the cavity of the abscess

3 *Chronic Synovitis of Left Knee* —Here is a boy that is said to have a chronic inflammation of the knee-joint, due to an accident, which for a time, produced pain without much swelling For some time the patient was able to go around with but little discomfort He awoke one night and complained of pain in the part, was supposed to have hurt it against the bed, but was known to have received a kick on the knee some time after, making the inflammation much worse His father, a blacksmith, has constructed a modification of Sayre's apparatus for making extension, that meets the indications in the case very nicely

This apparatus instead of having the key at the side, (like Sayre's) for controlling the degree of extension, has a flat piece of steel, with buttons upon it, that fit into holes in a corresponding piece of steel above, and when these are in place, a small band of metal slides over the spliced joint of steel, and thus holds the mechanism firmly in place At the upper, as well as the lower ends, these flat pieces of steel are strongly attached to bands of brass, that, form, when in place, complete circles around the boy's leg and thigh These circles are made with a hinge at one part of their circumference, and at a point directly opposite, a slot has been cut in one end, that fits over a small staple on the other end, and when adjusted, a little loop of brass slides down over the joint thus formed, firmly securing it Sayre puts strips of adhesive plaster all the way round the ends of the apparatus, to prevent any sliding motion of the appliance

This case of chronic *synovitis* is a result of one or two acts of violence, and the irritation caused by the patient running around considerably upon it He does not belong to a tuberculous family The mechanical irritation of constant walking prevents the knee from making a spontaneous recovery, which it would accomplish in most cases, if not predisposed to tubercular infiltration In rheumatic synovitis, we do not make use of extension, but in this case there is no rheumatism and extension is necessary In this case they have used the ordinary diachylon plaster to hold the apparatus in place, do not use it in your practice for such purposes, for you will find that the common rubber plaster is much better In walking, this patient should not allow the lame leg to support his weight, but should keep that foot off the ground entirely

4 *Inflammation of Ligaments and Subcutaneous Tissues of Internal Malleolus* —This little girl has an injury of her foot, caused by an accident, probably jumping out of bed There is a large red swelling on the inner *malleolus* It is not *synovitis*, for it does not hurt the child when I press the synovial surfaces together, and made slight movements under pressure There may be a slight inflammation of the ligaments, for she resists a little when I put them on the stretch Mainly, however, this is an inflammation of the skin and subcutaneous tissues A good treatment is to apply to the part iodine and glycerine, one part of iodine and three or four parts of glycerine and water I like better, however, some simple astringent lotion, *e g*

Let her take a few folds of linen or absorbent cotton saturated with the solution, and apply to the parts, and as soon as the moisture evaporates apply more There are a great many preparations that could be used to advantage in cases similar to the one before us Solutions of the following substances are useful Chloride of iron, sulphate of copper, nitrate of silver, tannic acid, sugar of lead, bichloride of mercury, alum, etc etc Several of these preparations are apt to become irritant as the solution concentrates by drying upon the skin, for instance, chloride of zinc, nitrate of silver, and bichloride of mercury—they may at last have even a caustic effect Hence the skin should be washed with soap and water once in forty-eight hours, when such solutions are used As this patient will not be under our control, it will be safe to use a solution of alum, which is not caustic in any strength

The *cellulitis* in these cases has been said of late to arise from malaria, but whether it is so or not I cannot say

5 *Chronic Synovitis of Right Knee with Floating Cartilage* —Here is another patient with an inflamed knee, which is also the result of an accident A horse kicked him there two years ago, though it did not hurt him much It began to swell, however, almost immediately, and has remained in a swollen condition for the greater part of the time since There is not much pain in walking or standing, but when the leg is flexed a little more than usual, he has considerable pain It is a case of *synovitis*, gentlemen Now, how do we know it is *synovitis?* Because, in the first place, there is a surplus of the synovial fluid in the cavity of the joint, secondly the *patella* is slightly elevated, thirdly, it hurts him to bend the joint Motion is limited on account of a thickening of the ligaments It is essentially a nearly pure *synovitis* The patient received another blow on the same knee, about a month ago, but this last injury was not sufficient to produce a swelling A piece of cartilage was dislodged by the first contusion, and was thereby transformed into what is technically termed a "floating cartilage" These loose bodies are supposed to be formed by the breaking off of pedunculated growths of cartilage, which exist in many knee-joints "Floating cartilages" are very apt to cause considerable trouble When lying in some pocket or fold of the synovial membrane, they are harmless, but when, from some sudden twist or movement, they catch between the bones, they cause violent pain, and compel the patient to lie or sit down, until he can carefully dislodge the treacherous

lump from its painful position Frequent repetition of the accident produces *synovitis*, and may even terminate in suppuration and *caries* of the joint Hence, in bad cases, operative procedures are necessary to extract the cartilage On inspection of this patient, you can distinguish a prominence, instead of the usual depression, each side of the *patella* In case of the removal of a "floating cartilage" according to the old plan, without antiseptics, about one case in seven died Careful antiseptic precautions must be taken in the operation of extracting a detached piece of cartilage As this patient will remain in the hospital, we will have him go to bed, and will secure immobility by extension with a weight and pulley Later in the case, an extension splint will be adapted to his leg, and a cure probably be attained My practice is to use a straight tin or brass splint, concave, so that it will fit the limb nicely, and provide it with extension bands, as explained to you in a former lecture

6 —*Fracture of Forearm* —This boy has a fractured forearm, the injury occured five weeks ago, but we told him to return occasionally to have the arm dressed The day I attempted to reduce the fracture, I experienced a considerable difficulty in approximating the ends of the broken *radius*, I was obliged to introduce a *tenotome* to sever the tissues that had become entangled with the ends of the bones, in order to have a better apposition of the fragments, which enables me in a great measure to overcome the difficulty When the sharp ends of the fractured bone imbed themselves thoroughly in a muscle or other organ so as to have a stratum of firm tissue separating the fragments, no union will take place I thus succeeded in obtaining a reduction of the fracture There is some slight irregularity of both bones present in this case, but the occurrence most to be feared is the loss of rotary motion, consequent upon the action of the *pronator quadratus* in drawing the ends of the fragments toward the centre of the forearm, so that they strike, instead of rolling freely past each other in rotation In the present instance the rotation is good We will, however, apply the splints for another week, as the parts are weak and need protection in case of accidental falls Absolute perfection in all respects is rarely obtained after fracture of the forearm, but by diligent attention you will obtain good and useful members in the great majority of cases

PNEUMONIC ABSCESS[1]

BY EDWARD F WELLS, M D ,

OF MINSTER OHIO

The daring boldness and, in some instances, the brilliant success, with which destructive processes within the lungs have been recently attacked by the surgeon lend, together with the inherent importance of the subject itself, an absorbing interest to my theme The advances made by these pioneers upon a hitherto untrodden field justly challenge the admiration of the professional world, and I fear that only adverse criticism awaits any one who attempts to run counter to the now popular current in the management of pulmonary abscesses Yet the principal object of this communication is to call attention to the well known, but often illy appreciated fact that, not only a few, but many of these cases recover without an operation, and that, a diagnosis having been made, it does not always follow as a corollary that an external evacuation of the purulent collection is the sole, or except in rare cases, the most appropriate remedy

I desire, however, that my position be not misunderstood That operative measures are necessary and advisable in some infrequent and properly selected cases I am not only free to admit, but also to advocate Indeed, I have myself assayed the operation in one case, and proposed it in another—both of which recovered by the powers of Nature and are living and well to day I have incorporated in this paper the histories of quite a number of cases which have recovered under expectant and medicinal treatment, and I think that the observation of every one present will bear me out in the belief that I do not stand isolated in my experience in this particular On account of the vastness of the entire subject of pulmonary abscesses I will confine my remarks to those occurring as a consequence of pneumonic fever

That the issue of pneumonic inflammation in abscess is a rare event is affirmed by the vast majority of writers,[1] although I quite agree with those who consider its rarity as having been generally overrated [2] On the contrary it certainly is not so common as the older authors[3] believed, for it is clear that they must, in many instances, have mistaken tubercular vomicæ and post mortem breaking down of tissue, for pneumonic abscesses

Laennec,[4] with his vast experience, extending over a period of twenty years, and after having made several hundred dissections of pneumonic subjects, met with abscess only five or six times Andral,[5] with an equal experience, met with but one case in an adult and two cases in infants Bronsius,[6] with extensive facilities for observation, observed but a single case, and that was caused by a foreign body Chomel, in seventeen years' pathological work, saw but two cases Trousseau,[8] in a quarter of a century's practice, had never encountered a case, although he then met with two within a week Bouillaud[9] met with only two or three cases Swett[10] says that he never encountered an example, although in another place[11] he gives the details of a case Elliotson[1] saw only two cases, and Gendrin, Honore[3] and Romkaud[4] met with one each Of 319 fatal cases occurring in Washington in 1878, abscess was found but once[5] Sturges[6] denies that abscess is ever a consequence of the pneumonic process[7] On the other hand Baillie, who probably correctly reflected the opinions of British physicians of his day, considered abscess of the lung as of frequent occurrence, and this view was shared by Crichton,[8] Cullen,[9] Heimly,[10] and others Stokes[11] and Copland[12] content themselves with the conservative statement that it is a comparatively uncommon event, but that they believe its rarity to have been overestimated Mercier[13] observed abscess four times in seventy cases of senile pneumonic fever, Flint[14] met with it four times in 133 cases of adults, and Delafield[15] twice in 123 fatal cases of all ages I have myself met with abscess nine times in 413 cases of pneumonic fever This does not include cases of gangrene, with abscess, nor those in which a foreign body was the cause unless pneumonia was actually present Excluding the cases in which a foreign body was the prime cause and the number is reduced to seven

If every case of pneumonic fever accompanied by purulent expectoration were considered as one of pulmonary abscess, we would find plenty of them If, however, to complete or confirm the diagnosis it be required to demonstrate the existence of a cavity by means of unequivocal signs and symptoms, in the case of the living, or by an autopsy in the case of the dead, they will be encountered much less frequently But even the evidence of the dead house must be accepted with caution, because an inflamed lung in the stage of gray hepatization is often exceedingly friable and will readily break down under very slight pressure, drawing or jarring Such a lung, after being roughly handled, may exhibit, at points, the strongest suspicions of abscess without any being actually present

Laennec[16] long ago called attention to this fact in the following words "When we forcibly drag from the cavity of the chest an inflamed lung attached to the costal pleura by old cellular adhesions, it frequently happens that the parts most infiltrated with pus give way under the fingers, or, without suffering any external wound, yield internally under the pressure so as to form a soft sanious mass which an inattentive observer might mistake for a collection of pus "

Two general classes of abscesses may be mentioned the encysted and the non encysted It is probable that all pulmonary abscesses would be bounded or lined by a limiting membrane were time enough allowed for its formation[17] This membranous wall bears the same relation to the abscess that a granulation surface does to an ulcer It prevents absorption of noxious materials, continues for a time to secrete pus, and finally contracts and closes the cavity In non-encysted abscesses the line of demarcation between the purulent matter and the intact tissue may be sharp and well defined or the contrary—usually the latter—and after evacuation the walls may be smooth and regular or uneven, ragged and shreddy

Pneumonic abscesses vary in size from the most insignificant dimensions to those occupying the entire lung

Chomel[1] saw an abscess which was six inches long, four inches wide and three inches thick Stokes[2] records a case of very extensive abscess Malloy's[3] *patient spat out, at one time, over* half a pint of pus Sedgwick[4] removed with a trocar more than a quart of pus at one, and three pints at another time from the same patient[5] In one case an abscess as large as the fist was found in the right lung,[6] and in another more than half the lower lobe of the right lung was an abscess cavity, with a second abscess at the base of the left lung[7] Fowler[8] reports a case in which the abscess occupied three fourths of the right lung—the whole of the middle and lower lobes being hollowed out—and which contained three pints of pus Hourmann and Dechambre[9] observed a case in which the abscess occupied the greater part of an entire lung In a patient who died in the Charleston City Hospital the entire left lung was disintegrated, presenting a honeycombed appearance, and filled with pus[10] In another patient who died in the Marine Hospital, on Bedloe's Island, the entire right lung was found to have totally "disappeared and was replaced by a cavity filled with gray purulent fluid "[11] Radek[12] evacuated, by incision, a quart of pus from the right lung Sutton's[13] case of operated abscess involved the entire lower lobe of the left lung[14]

According to most writers[15] abscess of the lung is oftenest met within the upper lobes but, judging from the published cases of others and my individual experiences, I am convinced that this is an erroneous opinion, and that the lower and middle lobes—those in which pneumonic consolidation oftenest occurs—are most frequently affected They are usually single but may be numerous, and many cases are on record in which abscesses have been found in both lungs[16]

Abscess of the lung is the result of excessive cell production in the parenchymatous tissue, leading to innutrition, softening and destruction of the supporting and form giving structures of the lung[17] Even since Cohnheim[18] demonstrated the escape of the white blood corpuscles through the unbroken walls of the capillaries, pathologists have very generally acknowledged that the formation of pus is a compound process, consisting in an escape of blood plasma and leucocytes from the blood vessels, an abundant proliferation of the cellular elements in the surrounding tissues, and finally the breaking down and liquefaction of all these structures In the lung minute foci of softening occur, and the full size of the abscess is attained by the breaking down of the barriers between these and their coalescence

In many cases of pneumonic fever there comes a time when the supporting structures of the affected portion of lung have become greatly softened and weakened by this cellular proliferation, deposition of fluids and leucocytes and lack of proper nutrition

No great flight of the imagination is required to conceive that under such circumstances the integrity of the parts hangs upon a very brittle thread Abscess is imminent and may be brought about by even trivial causes For many years I have kept this contingency steadily in view in the management of my pneumonic patients as they approach the period of crisis, and for some time thereafter I attempt to keep the parts as quiet as possible, easing the powerful and convulsive cough, forbidding all rapid and forcible movements of the patient, and even practicing percussion with lightness and care

Of course, there are other and more efficient agencies besides local injury which are instrumental in the production of an abscess I am well aware that in those cases in which death of the tissues has occurred, no amount of care can prevent their destruction, and that in those cases at the other end of the pathological scale, in which the circulation remains good and the connective tissue is not imperiled, no amount of neglect or rough handling can cause an abscess to form It is not to either of these classes to which my remarks are applicable, but to that middle and larger class, in which the chances for or against local destruction are more evenly balanced You may inquire, and with reason, why it is that I can produce such a large array of abscesses if care in this particular is an important point, and if I exercise it in my practice as I have stated I will reply to this by saying that all of my cases, save two, came to me second hand Of 297 cases of pneumonic fever, treated solely by myself, only two eventuated in the formation of an abscess

Pneumonic abscess has been described as a slow process, requiring a long time for its completion,[1] but it only requires a cursory examination of the published cases to be convinced that this is an erroneous proposition Personally, I do not believe that the pneumonic process is ever at a stand-still, there is a constant change, and when the acme is reached repair or destruction begin at once and usually pursue a rapid course Unless the whole of the inflamed portion contribute to form the abscess, the parts not destroyed and not in immediate proximity to the walls of the cavity usually clear up and regain their functions in the ordinary length of time Bolles', however, records a case in which there was no perceptible improvement in the general or local conditions until after the evacuation of the abscess on the forty-first day

Pus here, as elsewhere, may be absorbed and the abscess disappear, but this can only occur in minute collections The absorbents may, however, take up the serum, and leave the cellular elements behind as caseous mass This residuum may remain a long time dormant, but it is always an element of danger and may at any time imbibe moisture, soften, liquefy again and pursue an ordinary course One of my cases was of this kind

Case I —Mrs I , aged 25 years Two and one half years ago she had an attack of pneumonic fever, affecting, locally, the base of the left lung From this she never entirely recovered , cough, fever, night sweats, emaciation and prostration continuing for many months Gradually these symptoms subsided and she regained a portion of her former weight and strength The cough left her entirtly and she considered herself well, although she continued pale, easily fatigued and short of breath on the slightest exertion Last August her cough returned, with fever and pain in the left side For a week there was only a scanty mucus expectoration, but on the seventh day she brought up, in a few moments, nearly half a pint of thick, creamy pus At first the discharge was quite free, amounting to three or four ounces in the twenty four hours, but the quantity rapidly diminished to one or two drachms upon rising in the morning The discharge was much more easily effected when she lay upon the right side Previous to the discharge of the abscess there was dulness on percussion and absence of the respiratory sounds at the base of the left lung The heart was not displaced and there was no bulging of the intercostal spaces After the abscess burst there was tympanitis and loud gurgling Improvement rapidly followed and she is now almost well She coughs and expectorates a muco purulent matter occasionally, but sometimes goes a week without doing so There is yet slight dulness and a weakness and tubularity of the breathing in the affected area, with moist râles upon forced inspiration The left side is three fourths of an inch less in measure than the right A curious point in this case is the fact that the left breast ceased secreting milk—the patient was nursing a ten months' child—whilst the right was unaffected

By far the most common, and I am sure the most desirable, termination of a pneumonic abscess is by an evacuation of its contents through the bronchi In a certain proportion of large abscesses, the opening is into one or more of the neighboring cavities or through the the thoracic walls

Solon[1] reports a case in which the discharge occurred into both the pleural and pericardial cavities, and Pel gives a case which proves that the pus may sink down in front of the heart in such a way as to simulate a purulent pericarditis, an illusion which may not be dispelled by an operation In a case in which a large abscess occupied the right lung, the pus, after penetrating through the layers of the pleura and diaphragm, gravitated downward in front of the colon and formed a small cavity to the front of the cæcum[3] In yet another case, in which the right lung was also the seat of the abscess, the pus had made its way into the sheath of the psoas muscle and finally appeared as a fluctuating non inflammatory swelling in the groin[4]

Subsequent to the discharge of the abscess it may pursue one of several courses It may remain unaltered until the death of the patient It may become lined with false membrane and surrounded by a hard cellulo fibrous wall and remain permanently Or, finally, it may contract and become obliterated[5] When an abscess has existed for a long time, it approaches as nearly as possible the circular form, and its walls are lined with a smooth secreting membrane[6] When the abscess is of the largest size, its perfect obliteration is, perhaps, impossible, but when of more moderate dimensions this may occur, although with difficulty After its closure, the former site in the lung is marked by a puckered cicatrix If it has been a large one, the walls of the chest are depressed over its former seat, and if situated near the surface and with pleuritic adhesions, there may be a decided depression of the external soft parts[8]

CASE II —Mr J B , aged 57 years, was attacked at Christmas, 1876, with pneumonic fever, with consolidation of the entire left lung Crisis occurred on the eighth day, and a few days later he began sitting up, yet his cough, instead of diminishing, became more severe, convulsive and racking After a few days fever returned, with profuse perspiration, jaundice, anorexia and vomiting Expectoration had been scanty and muco purulent until January 12, when it became copious and almost wholly purulent The symptoms improved somewhat after this, but after a couple of days the expectoration suddenly ceased, and he became worse than before I saw him for the first time at this juncture The pulse was rapid, temperature elevated, skin bathed in perspiration, breathing embarrassed and expression anxious Under the left clavicle, over a space as large as the palm of the hand, there was dulness on percussion, tubular breathing and moist rales around the circumference, and absence of expiratory sounds in the central parts Two days later, with free purulent expectoration there was heard, on deep inspiration, gurgling at the spot where respiration was before absent When the patient lay upon his back tympanitis was well marked, but was somewhat obscure when he assumed an upright posture The abscess discharged for various periods at irregular intervals, with frequent suppressions When the discharge was free his condition was much ameliorated, but when it became scanty or suppressed hectic symptoms at once supervened The discharge became more and more regular, and the patient improved so much that he was able to leave his bed by the first of March, and was quite well in four months more A month ago I examined this gentleman, and now, nearly ten years after his illness, auscultation and percussion afford no evidence of any impairment of function Between the first and second and between the second and third ribs, in front, however, the soft parts are considerably depressed and contrast markedly with the condition on the right side

Abscess is likely to follow the pneumonic process in all sorts of patients—the weak and the strong, the old and the young—none escape, and none are peculiarly predisposed

Friedleben[1] considers infants more prone to abscess than adults Billard met with this condition in a child only twenty days old, and Depaul[3] has published a case in which the abscesses formed during intra uterine life Mercier[4] and Hourmann *et* Dechambre have detailed cases in octogenarians, and one of my patients, only recently recovered, is 74 years of age

CASE III —Mr B H , a retired farmer, aged 74 years, was attacked about the first of February, 1885, with pneumonic fever, with hepatization of the base of the left lung In ten days he was thought to be convalescent, yet he did not improve His cough continued and became more severe and convulsive He lost weight and strength from day to day I first saw him on March 16 He had continuous fever, with evening exacerbations , very profuse and effusive perspirations , a severe, paroxysmal and distressing cough, which was often accompanied by vomiting expectoration of frothy mucus , pain of a heavy, expansive and dull character in the left side , dyspnœa on exertion, etc , etc There was dulness over the lower lobe of the left lung, with bronchial breathing and moist râles along the upper border of this area, and absence of all respiratory sounds at the extreme base There were no changes in the external soft parts, and the heart was not displaced He had diarrhœa, his urine was scanty and deposited a copious sediment of urates, and his feet and legs were œdematous A puncture with the hypodermic needle in the eighth interspace in the axillary line revealed the presence of pus at a depth of an inch and a quarter An operation was proposed, but was declined by the patient The puncture with the needle gave rise to a severe paroxysm of coughing, ending by bringing up a small quantity of pus which was slightly streaked with blood The patient and attendants united in declaring that no such sputa had been previously seen The expectoration now became purulent, and increased so much that on the following day he brought up about four ounces of creamy pus, which was interspersed with small and dark sanguinolent masses, and had a fetid smell Evidences of a large cavity were now abundant and conclusive After a week rapid improvement took place The fever declined, the exhausting perspiration ceased, appetite and digestion improved, the diarrhœa was checked, the urine became free and clear, the œdema disappeared, and he gained in strength and spirits The purulent expectoration, which was occasionally fetid, continued, in diminishing quantity, for two months, when it ceased to appear regularly I saw this gentleman on October 30 There is still dulness at the extreme left base, with loud, harsh and cavernous sounds on deep breathing and almost entire absence of all sounds with ordinary respiration A deep, forcible inspiration brings on a peculiar convulsive cough and the expectoration, with much effort and gagging, of a small quantity of muco purulent matter He is now the very picture of robust health in old age, considers himself perfectly well, and weighs 190 pounds, which is more than he has done in thirty years

The symptoms of pneumonic abscess vary much in different cases In many the acute symptoms of the initial fever decline and the patient appears to be on the highway to recovery, when, at a variable time afterwards, the remaining symptoms are aggravated and new ones appear upon the scene The cough, which had not ceased, increases in severity and becomes more frequent and paroxysmal The fever, which may have nearly or altogether disappeared, is again a prominent feature, especially in the evening Profuse perspirations follow the febrile exacerbations The spirits decline, the expression is anxious, the strength fails, the patient again takes to his bed, and altogether he comes to a most alarming state It must be admitted, however, that in some cases the symptoms do not point very clearly toward pulmonary suppuration, and in others the abscess remains entirely latent, and is not suspected until its discharge or an autopsy discloses its presence The formation of pus in the lungs is not often accompanied by signs, as in other situations,[1] yet most of these patients will be found very susceptible to the influence of cold, and complain of feeling chilly with the least draught of air, or even when well protected from cold This was true of one of my patients

CASE IV —B S , a farmer, aged 34 years, was taken, October 30, 1876, with pneumonic fever, locally affecting the lower two-thirds of the right lung The malady ran an ordinary course, and by the tenth day there was no fever and but little cough Shortly after this the cough increased in severity, and fever with profuse perspirations came on The knees were always cold and they could not be warmed His appetite, which had become pretty good, failed, he was restless and sleepless, was delirious at times, and became greatly prostrated Auscultation and percussion revealed nothing decisive, although it is noted that at the level of the nipple, in the axillary line, the respiratory sounds were almost absent and at this point forcible percussion was illy borne The temperature ranged between 99° and 101°, and the pulse at about 100 On the thirty first day of his illness the abscess evacuated itself through the bronchi No reliable information could be obtained of the quantity of pus expectorated on the first day, but on the second it was about two ounces The quantity gradually lessened, and ceased within a month After the evacuation of the abscess there was obtained abundant evidence of a cavity The patient recovered entirely in about two months, but died two years later from acute pulmonary congestion, brought on by excessive exposure to intense cold At the autopsy the lungs were found intensely congested—almost black—and the bronchi full of watery fluid In the middle lobe of the right lung, near its upper and outer border, there was a fibrous nodule of the size of a cherry, from which radiated fibrous bands in different directions

Previous to the opening of the abscess, the cough, as before stated, is very severe and convulsive resembling the paroxysms of whooping cough[1] Afterwards the character of the cough is altered, by attaining a quality peculiar to itself, which may be vaguely described as having a high pitch and a metallic quality and conveying the idea that, although the sound originates in the lungs and the larynx, yet it is greatly reinforced by reverberations in the naso pharyngeal cavities This applies particularly to basic cavities with but scanty expectoration If the cavity is located in the apex, or if the discharge is very free and easily affected, these qualities are not so marked If the cavity is large and empty and communicates with a large bronchus, the cough is cavernous in character My impression is that not[2] many of these abscesses open into large bronchi, for the reason that they are usually peripheral, rather than central

---

[1] Arch f Phys Heilk 1847 S 66
Mal des Enfans
[3] Bull de la Soc Anat T XII p 273
[4] Op cit
[5] Op cit

[1] Sturges Op cit p 60

The expectoration has a peculiar turnipy flavor,[3] and at first is usually fœtid, but after standing awhile it sometimes acquires a rather pleasant odor, resembling that of cowslips [4] The odor may be gangrenous from cavernous decomposition, without there being any sphacelus as was demonstrated by autopsical examination in Pereira's[5] case The breath may be perfectly sweet, or constantly or only occasionally offensive [6] It is, to my senses, in many cases, peculiarly sweetish and sickening If the pus becomes decomposed in the abscess cavity and the respired air has free access thereto, it will certainly be fœtid, otherwise not

When the discharge of pus occurs through the bronchi, it is likely to come on suddenly and is more or less profuse according to the size of the abscess, the resiliency of its walls and the size and potency of the opening The matter is of a creamy consistence, a yellowish or greenish color, and may be mixed with small quantities of blood and elastic tissue The discharge is often suppressed for a longer or shorter time when, suddenly, especially after changing the position of the body, a more or less copious expectoration of almost pure pus takes place The amount expectorated in twenty four hours varies from a very small quantity to more than a pint I am satisfied that the very powerful cough, often accompanied by vomiting, met with previous to the evacuation of a pulmonary abscess, is an efficient agent for the rupturing of the walls of the cavity and the discharge of its contents This was exemplified in one of my cases

CASE V —N J , female, aged two years About the first of February, 1884, whilst eating peanuts, she choked, coughed severely and spasmodically for several minutes, lay down to sleep and awoke in an hour with fever and a painful cough After a few days she improved, but soon relapsed again Exacerbations, followed by temporary improvement, continued for more than two months, when she came under my care At this time the cough was not frequent, but it was very severe and convulsive, and almost always ended in emesis It very much resembled whooping cough, for which it had been mistaken She had irregular febrile exacerbations, which were followed by profuse perspiration and was much emaciated There was dulness, not flatness, over the entire left side of the chest as high as the second rib, and in this area the respiratory sounds were everywhere tubular, but weak, except above and external to the nipple, in the axilla, and under the scapula, where they were entirely absent The heart was not displaced and there was no intercostal bulging I was informed that a few days previously, the skin above and to the left of the nipple had been reddened, swollen and painful, but this had disappeared I had not been informed of the origin of the illness, and abscess being diagnosticated, I determined to operate On April 11th, the child was put under the influence of chloroform by Dr Costello, and a long hypodermic needle was thrust into the lung just external to the angle of the scapula and pus found at a depth of an inch and a quarter Making an incision down to the pleura, it was found by Fenger's[1] test that adhesions had not formed In the axilla, the abscess was found somewhat nearer the surface, but here adhesions were also absent For some reason pus was not obtained anteriorly I now made a number of punctures about the seat of my first incision, hoping that adhesions would follow, and postponed the completion of the operation Absolutely no ill effects followed I was now, for the first time, informed of the peanut incident, which threw a flood of light over the entire case, and which explained why the abscess lay so deep and the absence of adhesions Six days later, after an exceptionally severe paroxysm of coughing, she expelled a piece of peanut nearly one fourth of an inch in each of its dimensions, together with more than an ounce of creamy and fœtid pus Signs of a cavity, incompletely emptied, were now manifest After this she improved very rapidly and was quite well in six weeks At the present, there are no signs to indicate that she had ever been the subject of a pulmonary abscess

Aretæus,[2] Galen,[3] Bontius,[4] Tulpius[5] and others of the ancients, speak of the expectoration of pieces of lung tissue in cases of abscess, but at this late day their observations must be accepted as somewhat apochryphal In one of my cases the patient presented me with a small piece of a fleshy substance which he was sure was a part of his lung The microscope proved it to be a portion of beefsteak which he had eaten the day before

CASE VI —Mr J B , a farmer, aged 66 years, was attacked with pneumonic fever, affecting the right lung, in February, 1881 After the eighth day the acute and urgent symptoms declined, yet the cough continued and he lost flesh and strength After having been ill three weeks he spat out, at once, a considerable quantity of pus Purulent expectoration continued daily, in diminishing amounts, for more than three months, and occasionally for a year I saw him first at the end of a month and readily detected a cavity at the base of the right lung When the nature of his case had been explained to him, he said that he understood it thoroughly, and the next morning he had ready for my inspection a piece of his lung, which he had expectorated, and which, on examination, proved to be a piece of beef steak In the case of this patient there was sometimes fœtor of the breath in the morning, but it always disappeared after free expectoration After a short time he began to improve, and in my experience I have never seen such an appetite developed in a convalescent patient as this man displayed He literally dined hourly In August, and again in November, he had hæmoptysis He is now a hale and hearty old man, yet the peculiar cough is still developed whenever he catches cold, although I can detect no sign of a cavity

The diagnosis is not very difficult in most cases if attention be given to the foregoing symptoms, and a careful physical examination is made If the abscess is not evacuated, of moderate or large size and superficially located, there will be found dulness on percussion, with diminution or absence of the respiratory sounds In the neighborhood will be noticeable the ordinary signs of inflammatory consolidation If the abscess lies deeply or is small these characteristics may be greatly modified or absent, and under these circumstances the diagnosis must be based largely upon the symptoms, and will sometimes remain doubtful The hypodermic or aspirating needle may be safely and advantageously used for diagnostic purposes After the abscess has discharged its contents the ordinary signs of a cavity will be present In this connection I must again insist that great importance should be attached to the history and symptoms of obscure cases—cases in which the physical signs are insufficient in themselves to lead to a diagnosis In one of my cases I was compelled to rely exclusively upon the symptoms for diagnosis

CASE VII —Mr J S , a farmer aged 42 years, was engaged during the first week in January, 1880, in hauling clover Whilst at work he took a severe chill, followed by all the ordinary symptoms of pneumonic fever At first the entire left lung became hepatized, and on the third day the base of the right also, with great dyspnœa Resolution occurred in due time in the left lung but not in the right The cough continued and became more powerful and paroxysmal, deep breathing caused pain and cough, evening fever and perspiration were marked, and the patient became greatly prostrated and discouraged The expectoration was scanty, muco purulent, and had a salty taste The urine was scanty and loaded with urates During the fourth week he occasionally raised a small quantity of pus, which had a sweetish, turnipy and nauseous taste On some days this was the only kind of expectoration, and when this was the case he was pretty sure of a night without fever, but if the sputa were scantier, less purely purulent and with a saline flavor, fever and perspirations invariably occurred When the expectoration was purulent the urine was also more copious and clearer At the end of the sixth week he expectorated a thick mass of pus in which was incorporated some small black objects, which were supposed to be pieces of clover hull From this moment improvement began For ten or twelve days the expectoration continued purulent The signs of consolidation disappeared very quickly, and he was quite well within a month No signs of a cavity were ever detected

Abscess of the lung may cause pyæmia,[1] and it has been found to be rather frequently associated with cerebral abscess Phthisis followed in one of my cases

CASE VIII —B S , male, aged 18 years, with a strongly inherited tendency to consumption, was attacked with pneumonic fever in March, 1879 The lower two thirds of the right lung was hepatized On the tenth day, and with no amelioration of the symptoms and no suspicion of abscess, he suddenly expectorated a tea cupful of pure pus For several days he expectorated from a half pint to a pint of purulent matter in twenty four hours, but the quantity gradually diminished and ceased in six weeks Signs of a cavity in the posterior part of the middle lobe of the right lung were manifested For a while he continued in a most desperate state, but he afterwards improved very much During the summer he coughed only on active exertion, and the signs of a cavity disappeared, yet he continued too weak to work and failed to gain flesh During the next winter he caught cold often and developed a constant cough, and died in the summer of 1881 with all the symptoms of fibroid phthisis

In the last of my series of cases a lady who was informed by her physicians that she had pulmonary consumption, has been entirely relieved of all her symptoms by the discharge of an abscess

CASE IX —Mrs S , aged 37 years, has been an epileptic for twenty years She has had a cough, constant, although varying in severity, with progressive loss of weight, for two years This was not preceded by any illness On August 1, 1885, she had a rigor of three hours' duration, which was followed by fever, pain in the right side, rusty expectoration, etc I saw her on the eighth day, with a pulse of 136, respirations 35, and temperature 104 5° There was dulness on percussion over the right lung as high as the third rib, with bronchial respiration in front, and behind down to the angle of the scapula, but below this there were no breath sounds audible On the following day the temperature fell to 95° and the patient seemed to be *in extremis* From this she rallied, but the pulse and respiration rate remained high, and after two days there developed an evening fever with profuse and offensive sweating The paroxysmal cough was very powerful, often brought on vomiting and only caused the expectoration of an insignificant amount of muco purulent matter On the sixteenth day she suddenly brought up about four ounces of almost pure pus Purulent expectoration continued for nearly a month, when it gradually ceased She began to mend as soon as the abscess discharged, and is now quite well She now has better health than she has had for years Up to the tenth of November she had already gained twenty pounds in weight After the discharge of pus there was tympanitis, gurgling and cavernous breathing, but these signs have disappeared With ordinary breathing there is now a diminution of the respiratory sounds at the right base behind and at the side, and with forced inspiration there is loud crackling and moist râles Deep breathing causes a single dry cough, otherwise there is none

Pneumonic abscess is certainly a condition of much anxiety and gravity, yet, relying upon the experience which I have placed before you and the published cases of others, I think myself justified in believing that the danger has been greatly overrated by many authors[1] Not one of my patients died from the direct effects of the lesions, although some were old and feeble and others were greatly debilitated, and all were very ill indeed Necessarily there will always be a frightful mortality amongst those cases in which the abscess attains a monstrous size, or is discharged into one of the great cavities In most of these cases death is inevitable and must ensue early In those cases, also, in which the collection of pus is of more reasonable dimensions, but has an insufficiently free discharge, or in which dangerous complications occur, or which happen in cachectic and broken down constitutions, the death-rate will always be high But in the case of small or medium sized abscesses, with free openings into the bronchi, and in ordinary subjects, I hold that a fatal termination is the exception and not the rule When death occurs it may take place very early,[2] or it may be postponed for two or three months,[3] or even longer

Cockle[4] relates a case in which death occurred in ten days from the appearance of the first symptoms In this case the purulent cavity was only the size of a pigeon's egg, lined with false membrane and solid walls of considerable thickness The walls and contents were not fetid, although the breath and sputa had been In this case it is scarcely possible that the small abscess was the cause of death, which was probably due to the intensity of the original disease Molson's[5] patient, who was an intemperate woman, aged 35 years, began to expectorate large quantities of purulent matter on the tenth day of an attack of pneumonic fever The temperature, which had kept steadily at about 104°, fell quickly to 99°, and she died on the following day The abscess, which was large, was seated in the lower lobe of the right lung

If recovery ensues it may be either complete or partial, and the duration may be short or greatly prolonged

The ordinary treatment of pneumonic abscess has, until quite recently, been symptomatic and expectant Now, however, this field is being invaded by the operative surgeon, and the question of what is the best management of these cases is, in many minds, in an unsettled state As to the general results of the medicinal and operative plans of treatment, it can be said that the former, although fairly successful, leaves much to be desired in some cases, whilst the latter has not yet come up to our anticipations Unfortunately it may be said of the majority of the few cases which have thus far been submitted to operation, that the operation was a success—but the patient died Let us first consider the medicinal and expectant plan of management, and afterward the indications for more radical measures

There are some remedies which, I am sure, are of especial value in the treatment of these cases, and at the head of these I would place cod liver oil I usually prescribe it in the form of a recently prepared emulsion, combined with the hypophosphites of lime and soda or, what is better in some cases, muriates of ammonium and sodium It should be given in small doses, frequently repeated Phosphorus and the iodides of iron and potassium are useful in properly selected cases Strychnia I invariably prescribe as a tonic to the respiratory muscles, in order that the cough may be rendered more powerful and efficient Sage tea, atropia, etc, may be required in some cases to check excessive perspiration Mild counter irritating embrocations to the chest I believe to be useful, and I usually prescribe a terebinthenate mixture for this purpose

If the breath or sputa should be fetid, inhalations of iodine, carbolic acid, salicylic acid, turpentine and similar agents may be tried for the purpose of correcting this After you have experimented with the entire list you will regard turpentine as the most generally useful My plan of using it is to keep the atmosphere of the apartment constantly saturated with its fumes The cough is almost always a distressing symptom, and yet I believe that in this powerful cough lies much of the patient's safety, and consequently I am not in the habit of administering any sedative remedies for its relief In those cases in which, although an opening into the bronchi exists, the purulent and decomposing secretions are not promptly removed, with, always, ill consequences, an effort ought to be made to ensure the free and frequent evacuation of the cavity This may be done in a variety of ways A deep, forcible inspiration will often cause coughing, with the ready and efficient expulsion of the morbid matters

As a therapeutical curiosity the method of Gadbury[1] for evacuating lung cavities may be mentioned He forcibly inflates the lungs with a rubber hand-bag, forcing the air freely into all parts of the respiratory tract, which causes coughing and the expulsion of the accumulated cavernous secretions Rokitansky has proposed to make use of the benzoate of soda for the same purpose This agent is an irritant to the bronchial mucous membrane, and when inhaled in solution as a spray, causes prolonged and powerful coughing by which all the fluid in the tubes and cavities is expelled—thus literally washing out the lungs

Patients sometimes discover for themselves that when they assume some particular position the cavity is very readily emptied of its contents, and when this is the case they should be directed to place themselves in such posture at frequent intervals In some of these cases in which the discharging abscess cavity is situated in the base of the lung its closure may be hastened, sometimes very much, by the wearing of an elastic abdominal bandage, having a firm upward pressure, as I recommended some years ago in the treatment of empyemic fistula [1]

The diet should be nourishing and slightly stimulating Food should be given at frequent intervals, and not in excessive quantity If necessary, digestion may be aided by appropriate agents or supplemented by the use of artificially digested foods The regimen and nursing should be of the very best Particular care should be taken that the patient changes his position at suitable intervals, and, if able to do so, he should have easy exercise

Turning now to the operative measures which are available for the relief of purulent accumulations within the lung, let us consider first the conditions demanding an operation, and finally, the method of its performance Before an abscess of the lung has evacuated its contents it is perfectly evident that there are but two modes of procedure, the one pure expectancy, together with the treatment of symptoms, and the other the opening of the cavity by mechanical means Whether the one or the other of these is best and ought to be followed in any particular case must ever depend largely upon circumstances Among these may be mentioned the state of the patient, the locality, size and duration of the abscess, and the skill and tact of the medical attendant There can be no iron rule of universal applicability in these cases My opinion has been already given that the vast majority of these abscesses will evacuate their contents into the bronchi, with the eventual recovery of the patient In a certain proportion of cases, however, the discharge is into one or more of the neighboring great cavities, with, usually, a fatal result Has this ever occurred in the case of small abscesses? If it has my memory fails to recall the report of the case Would the external evacuation of a small abscess add anything to the dangers of the patient? Every one will admit that it does If, then, small abscesses generally result fortunately, through natural agencies, why should we subject our patients to a dangerous operation, offering at best only problematic advantages?

If to these objections to operating we add the acknowledged diagnostic difficulties in exactly locating the purulent depôt and the known failures of accomplished operators in striking it, I think we have abundant reasons for practicing expectancy in this class of cases But when we come to interrogate those larger abscesses the answers cannot be arrived at so easily nor made so emphatic The larger the abscess the more apt will it be to rupture into the pleura, pericardium, mediastinum, etc, with a probably fatal result Will an external opening always, or frequently, prevent this? Sometimes it will, and again it will not In the case of the largest of these abscesses death is probably inevitable, and an operation can do no good and may hasten the fatal issue Even in the case of moderately large abscesses recoveries are not infrequently reported after the expectoration of their contents Very few, indeed, have been cured by an operation Here, however, is the proper field for operative treatment and for further research, and after a wider experience has been gained in it the proper management of these cases may be more authoritatively formulated For the present, they must be left to the good judgment of individual practitioners Personally I should watch such a case in a sort of armed expectancy, pursuing a conservative course, yet ready to give my patient the doubtful benefits of an operation should occasion offer

[2] St Louis Med and Surg Jour Jan 20 1880 p 59

[1] Cincinnati Lancet and Clinic Oct 15 1881, p 348

In case the abscess has already discharged through the bronchi, the rule of action to be adopted is clearer, and may be stated as follows When the cavity is being freely evacuated, no matter what the symptoms may be, an operation is clearly inadmissible But if the opening in the bronchus is not of such nature as to allow of a free exit of purulent matters, or if they are prevented from escaping by other causes, and the patient is steadily losing ground and approaching closely to the danger line, an operation is demanded This, however, should not be done hurriedly, but rather delayed a reasonable time, for in some of these cases Nature enlarges the opening or removes other impediments to a free discharge, and improvement and recovery quickly follow

The first account of the external opening, by an operation, of a pulmonic abscess of which I have any knowledge, is given by Sedgwick[1] It is true that the operator thought he was treating an empyema, caused by the bursting of the abscess into the pleura, yet a careful reading of his paper will show that, like Radek[2] he was mistaken in his diagnosis The case, in abstract, is as follows A medical man, aged 58 years, was attacked with pulmonary inflammation, in the course of typhus fever, in the spring of 1850 Ten days after the onset of the pulmonary complication, symptoms of a large abscess in the lower part of the right lung appeared, and he began to expectorate purulent matter, with signs of a cavity A bulging developed between the sixth and seventh ribs at about their middle, and at this place there was removed more than a quart of stinking pus When the fluid ceased running, air in great abundance passed through the canula, and when the patient coughed, the current became so strong that it blew out a candle which chanced to be near The patient improved at once and the opening closed in three months He resumed his duties, but during the following winter he caught cold frequently, a relapse followed, and in the spring it became necessary to make a second operation, this time giving exit to three pints of pus Subsequently the opening was maintained patent by the constant use of a gutta percha plug an inch and a half long He regained moderate health, returned to his employments and died in 1857, seven years after the first operation An autopsy was not permitted During the past six years, the operation has been done often, and by a number of operators, both at home and abroad

Having, then, a patient with a large unopened abscess, or one which, although opened, has an insufficient discharge and who is steadily declining, and who is evidently doomed to a greatly prolonged illness or perhaps death, the good sense and discrimination of the surgeon will say that an operation is indicated and should be done This having been decided upon the abscess cavity should be exactly located with the hypodermic or aspirating needle, and this used as a guide in the subsequent puncture The locality selected for the opening should invariably be that point where the abscess approaches nearest the surface Generally the pleura is involved in the inflammation, the pleuritis plastic and the layers adherent over the purulent cavity The more chronic the case the more apt is this to be so Fenger and Hollister[1] say that if an incision is made down to the intercostal muscles, over the seat of the abscess, and a needle thrust into the lung it will not move synchronously with the respirations if adhesions are present, whilst a contrary condition is indicated by such movements If adhesions are absent several needles might be inserted through both layers of the pleura and allowed to remain until inflammation is set up, when, if the chest wall is kept quiet, adhesions may form and the operation completed at another time

The patient being under the influence of chloroform, an incision of suitable length is made in an intercostal space down to the pleura A medium sized trocar should then be slowly and gradually bored through the intervening structures until the cavity is reached, and the purulent contents allowed to escape Through the canula a drainage tube of soft rubber and a smooth internal extremity should be passed and allowed to remain Instead of the trocar the electro or thermo cautery may be used in opening the abscess, and this method is preferred by Albert, Koch and Fenger[2] The drainage tube must be shortened from time to time as the cavity contracts The outer opening should be covered by an absorbent dressing, which should be frequently renewed I should object to injections of any kind, and especially to those containing carbolic acid or other poisonous substance in any considerable proportion

In closing I will offer for consideration the following conclusions, which I think are warranted by the facts above stated

1 The issue of pneumonic fever in abscess is rare, but this rarity has been generally overestimated

2 These abscesses vary much in size and are most frequently found at the base of the lung

3 They may, in some cases, be caused by excessive jarring or other motion

4 They are usually formed rapidly

5 In some rare cases the purulent contents may degenerate into a cheesy mass, to again soften, liquefy and be discharged

6 The symptoms and signs are generally quite distinctive and sufficient for an accurate diagnosis

7 The majority of cases recover, but in a certain proportion a cure is impossible

8 Expectant and medicinal treatment has, thus far, given the best results and the majority of cases should be managed upon this plan, but under certain conditions the most radical measures for relief are not only justifiable but imperatively demanded

OBSERVATIONS UPON THE STRUCTURES TO BE INCLUDED IN THE SUTURES IN THE OPERATION FOR FIXING A FLOATING KIDNEY

BY L H DUNNING, M D,
OF SOUTH BEND INDIANA

The question which the writer will discuss more particularly in this paper is, Shall the Renal Capsule be included in the Sutures? That this is an important question and one that has not been definitely settled, those familiar with the medical literature of the last few years are well aware

The writer has deemed it advisable to refer to some of the statements of a few of the writers upon the subject Morris[1] states that "In Hahn's first two cases the sutures included the peri renal fat, and one of them was unsuccessful In the third case he included the renal capsule in the stitches, but with what result is not stated Gilmore[2] included the renal capsule but the suture cut its way out and set the viscus free Weir[3] included in one case the perirenal fat and was successful Morris concludes that "Experience will have to decide whether there is any necessity of penetrating the envelope of the kidney" He goes still further, and says, "It is not adequately proved that any suture is requisite to attain the end in view"

Lucas,[4] in a discussion at the annual meeting of the British Medical Association, says "Painful moving or floating kidney, being only a mechanical disturbance, admits of relief only by mechanical means Simple exploration and replacement through an incision in the loins, would probably be sufficient, in a majority of cases, for the cure of this condition, the adhesions resulting serving to retain the organ in position Stitching the capsule to the parietes, or, as it is termed, nephrorraphy, is a somewhat serious but still simple undertaking In eight patients in which it has been performed, the patients have all recovered and were relieved" In a previous article[5] the writer took the ground that if the peri renal fat and capsule are intact, *i e*, if they retain their intimate relations to each other and to the kidney, which may be ascertained when the organ is exposed by the incision, there is no need of including the nearer investing capsule The reasons for this conclusion were based upon experiments briefly stated Since the publication of that article the writer has made numerous experiments upon the kidney of animals just slaughtered, a few observations upon the kidney of the cadaver, and has had one opportunity to verify his conclusions by experiments made upon a patient during an operation for fixing a floating kidney

The animals seen by me and experimented upon were sheep, calves and beeves I was present when they were slaughtered and hung up, so that my observations respecting the kidney commenced a few minutes after the death of the animals When first hung up and opened, the organ in question in all the animals was quite movable, especially so in the sheep, in which it could be moved back and forth and up and down several inches, without doing violence to any investments of the organ or to the ureter, blood vessels or nerve The right organ was slightly more movable than the left and slightly larger It was found, on moving the kidney, that not all the perirenal fat went with it but that the organ was uniformly surrounded, except a small area upon the anterior inferior aspect, by an investment of fat that accompanied it in all its movements This investment was found to be quite firmly adherent to the renal capsule and the nerve vessels and ureter for a short distance nearest the hilum It was not so closely adherent, however, but that considerable freedom of movement of the kidney was possible within the investment By grasping the fat in the hand, just below the inferior portion of the kidney, and making gentle yet firm pressure the kidney could be made to ascend from three eighths to half of an inch, without doing violence to any of the tissues under observation

The fat investing the kidney was connected with that lying upon the psoas and quadratus muscles by irregular bands of adipose and connective tissue, so that the movements of the kidney were restricted to certain limits It was observed with considerable interest that the attachments of the adipose tissue to the capsule were quite as difficult to break up as it was to tear the adipose tissue These attachments seemed to me to be the strongest about the center of the two surfaces of the kidney and near the hilum That small area but lightly covered with fat possessed interest to me and was carefully examined On close inspection, it was found that a thin layer of connective tissue, with its attachments to the capsule, stretched across this surface and was lost in the adipose tissue surrounding it I tried, in various ways to forcibly remove the kidney from its investing fat without doing violence to that organ The only way I accomplished it, without lacerating the kidney, was previously incising or tearing the fat by squeezing it with the hands in various directions When the organ did leave its investment, the direction it was most prone to take was downward and forward

Before proceeding to another branch of the subject, let me briefly summarize There was found,

1 A normal, not exact, range of mobility

2 An investment of fat accompanying the kidney in all its movements, except an up and down movement, within its own circumference

3 The attachments of the tissue were as strong as the tissue itself

4 It was difficult to remove the kidney from its investment without lacerating it

Now, if it be shewn that these conditions are identical with, or analagous to, the conditions found in the living man, then we have some light received that will aid us in deciding the question Morris says experience will have to decide A part of the conditions I have described as having been found present in the lower animals just slaughtered I have been able to demonstrate as having been present in at least one human being On October 10, 1885, assisted by Drs Hitchcock, Kittering and McAllister, of this city, I did the operation for fixing a floating kidney, the patient being an unmarried female, 35 years of age. Before the operation, it was easily demonstrated that the right kidney, by a change of the position of the body, would move transversely across the abdomen about four inches and downward and forward about five inches. There was nothing unusual about the operation, except that the space between the twelfth rib and the crest of the ileum was so short that a slightly crucial incision was made, three inches long, commencing within two and one-fourth inches of the vertebral column, on a level with the lower border of the twelfth rib, and extending downward and outward. No difficulties were encountered in cutting down upon the kidney. As soon as the cellular tissue covering the adipose tissue was cut through, quite a quantity of that tissue projected up into the wound and was cut away with scissors. With a finger in the wound, I made search for the kidney and found it after well-directed pressure had been made over the abdomen. The kidney was observed to be uniformly surrounded by fat, except that the investment was thinner over the anterior inferior aspect of the viscus. This investment accompanied the kidney in its movements away from the incision. A portion of it was seized with dressing forceps and the mass (kidney and investment) was drawn down to the edge of the incision. Now, I could, and did for the most part, examine with the finger every portion of the external surface of the kidney. The envelope was found intact, as just described. With two fingers in the wound I could move the kidney slightly upward and downward in its fatty envelope, and further, could distinctly feel the upward and downward movement of the viscus during inspiration and expiration.

[2] Ibid

[3] N Y M Journal Vol 37 p 170

[4] JOURNAL AMERICAN MEDICAL ASSOCIATION Jan 1884 p 82

[5] THE JOURNAL Feb 21 1885

It is not likely that these points would have been all observed had not the experiments above outlined been conducted previous to the operation. Now was forcibly brought to my mind a fact I have never seen stated, viz. No means of fixing a movable kidney should be employed that does not comprehend and admit, to a considerable extent at least, the normal movements of the viscus during inspiration when changes of the position of the body occur. The mobility of this organ is undoubtedly Nature's method of preventing undue pressure being made upon it during respiration and postural changes. Undue and uneven pressure would undoubtedly induce disturbances of circulation, with its attendant evils, some of which might and would likely be disastrous.

Which method, then, shall be employed in anchoring the kidney, or, in other words, what structures shall be included in the sutures? Simple incision and replacement of the organ has been suggested, but I have not yet read or heard of any one who has had sufficient confidence in this method to employ it. I have no confidence in it since, in both cases in which I have operated, the kidney was inclined to slip away the moment the abdominal pressure was removed, or there was the slightest change in the position of the body of the patient. It would undoubtedly be the preferable method provided it were successful, for then fixation would occur without undue adhesions and with an unbroken capsule, both of which results are desirable. As between the two methods of suturing, it seems to me there are valid and conclusive reasons for adopting one and rejecting the other, and, in order that these may be made more apparent, the structure, attachments and office of the renal capsule should be considered. This capsule is made up of dense areolar tissue. In its structure the white fibrous tissue is largely in excess of the yellow elastic tissue, hence it is very firm and nearly inelastic. That it is practically inelastic may be shown by taking a strip of the capsule two inches long and half an inch wide, seize each extremity by a pair of forceps and make gentle yet firm traction, and it will be found that before any appreciable stretching of the strip will occur it will tear at the edges or at the limits of the grasp of the forceps. Take in the hand a kidney with the capsule intact. With a conjunctive forceps raise a portion of the capsule and separate it from the kidney over a considerable area. Now the capsule can be drawn away from the kidney, but in so doing the shape of the kidney will be invariably changed in ratio to the amount of force used, thus shewing a lesser density and greater elasticity of the structure of the kidney than that of the capsule. Other points may be observed. The capsule is easily torn if once an opening be made in it. Stitches passed with a needle with cutting edges tore out with less force applied than those passed with a round needle. The capsule is denser and thicker as it approaches the hilum. In this region the attachments are strong, the tissues dense and the capsule is two or three times as thick as elsewhere. That portion lining the sinus and reflected upon the ureter nerve and blood vessels is so strong and so firmly adherent that careful dissection or strong force is requisite to detach it. Here is a wise provision of nature, and here is found the great reason why a moving kidney pushed far away from its moorings, at times falling by its own weight or pushed downward by pressure, is not more frequently or more intensely painful.

Take the kidney in one hand and the ureters and vessels in the other. Hold the kidney firmly and make strong traction upon the cord. Now you can readily demonstrate that until the capsular adhesions are broken up or the capsule itself torn, there cannot possibly be any stretching of the nerve, blood vessels or terminations of the ureter, within the kidney, for in this effort all force exerted is expended upon the capsule, its attachments, or the structures to which it is adherent. If sufficient force be used, the kidney will be lacerated before the other structures will give way. This fact I noticed in my experiments, gentle yet firm force, intermittently applied, did, in a few instances, cause a gradual separation or giving way of the capsular attachments, and the stretching or traction upon the internal nerves, blood vessels and ureter could be readily produced. It seems to me probable that this sometimes occurs in the patient, and then occur the attacks of intense pain sometimes experienced by subjects of floating kidney. Two other offices of the capsule of the kidney may be mentioned. It acts as a barrier to the spread of inflammation to the kidney from surrounding structures or organs, and furnishes a surface for the attachment of its fatty envelope

In view of the facts stated, it seems certain that if the renal capsule be included in a sufficient number of sutures to hold the kidney firmly in position at the bottom of the incision, the normal movements of the organ will be entirely prevented, and thus it will be subjected to undue pressure This is the greatest objection to suturing the structure under consideration In truth, it would appear to be a sufficient reason for absolutely condemning such a procedure Other reasons opposed to such a procedure are apparent when the facts already stated are remembered Should the sutures cut their way out of the capsule—and this they would be likely to do since the movements of the viscus are from above downward, so that every respiration of the patient brings a strain upon the sutures in such a direction as to render them likely to tear or cut the tissues they include—we have then a broken capsule, which will render the attachments of the invest fat less effective, and in part remove the barrier to the spread of inflammation to the kidney It would also render less secure the attachments of the capsule to the organ near the hilum and thus diminish the protection to the ureter, blood vessels and nerves against violence in the movements of the kidney To some it may appear that the last mentioned danger is imaginary, or at least remote That it is remote may be conceded, but it is none the less real and is entitled to some weight in deciding the question under discussion

Having thus shewn what I deem valid and sufficient reasons for condemning the method of including the capsule in the sutures, it yet remains to shew the advantages and efficiency of suturing only the perirenal adipose tissue What we should aim at in this operation is to firmly fix the kidney in a favorable position, in such a manner as to permit of sufficient motion to prevent undue pressure being made upon it, and that too with an unbroken capsule The facts already stated in this paper are the basis of my conclusion that these desiderata can all be realized by stitching the investing fat to the edges of the incision This investment, with its attachments, when intact, are strong enough to permit the kidney to be favorably placed and held in position and when so held the organ will have considerable freedom for motion within the circumference of its envelope The capsule will be untouched Experience has shewn that in a vast majority of cases this method has been successful in anchoring the kidney and in affording relief If the nearer investing fat be intact and included in the stitches, the writer cannot see how anything more desirable for a good result can be obtained If failure be the result, it must be from causes independent of the method of operating

The writer now ventures the opinion that in cases favorable for operating and in which there were failures, either the kidney had left its fatty envelope or else there was little or none of it included in the sutures, and, furthermore, that in some of the cases in which the capsule was supposed to have been raised and penetrated, only a portion of this structure was stitched to the parietes In his first case, the writer now believes he was so deceived, for experiment has shown him how difficult it is to separate and lift away from the organ sufficient of the capsule to be included in the threads, even after the removal of all adipose matter

The writer's conclusions may be stated as follows

1 The kidney has a normal range of motion

2 The operation for fixing a floating kidney should comprehend and permit, so far as possible, this normal range of motion

3 The capsule should be left unbroken, and, if possible, free from adhesions

4 Stitching the capsule ignores the fact stated in the first conclusion and prevents the realization of the desideratum mentioned in the second, and from its very nature precludes the accomplishment of the second named desired result

5 Suturing the fatty envelope recognizes the truth of the first conclusion, and fulfils the indications of the second and third conclusions, hence it is the method greatly to be preferred

MEDICAL PROGRESS

MATERIA MEDICA AND THERAPEUTICS

Gelsemium and its Reported Antidotes —Dr Emil G Reyfuss, of Philadelphia, at the close of an article on this subject, draws the following conclusions from his experiments on animals

In the case of ammonia carbonate *vs* gelsemium, the results were not only negative, but we had increase not only in the number but also in the intensity of the convulsions, death being accelerated in every case

In the case of alcohol, the convulsions were of a milder type, but a fatal issue resulted in every case

The same negative results were noticed in using the above two reputed antidotes together at the same time, with the exception that the onset of the convulsions were of quite a mild nature, those occurring later were, however, very severe, ending in death

Morphine retarded death somewhat, and considerably moderated the symptoms

Atropine The same may be said of this agent as of morphine, it, upon the whole, affording somewhat more satisfactory results, though it did not prevent death occurring

I am led to conclude, from a careful study of this subject, based upon the results of my experiments, as well as on the collection of cases occurring in the human subject, that in treating a case of poisoning by gelsemium in the human subject an emetic may be given at the very onset One should not stop here, as little reliance can be placed upon the efficacy of the same, it appearing by reading the cases recorded that emesis took place only in one case in which emetics were used Owing to the easy obtainment of such stimulants as ammonia carbonate, brandy, and tinct digitalis, etc , these should be resorted to at once In addition, I would suggest the early and repeated use of small doses of atropine sulphate, given hypodermically to sustain respiration Of course external use of sinapisms, rubbing, electricity, artificial respiration, etc, should be resorted to in every case —*Therapeutic Gazette*, Oct, 1885

MEDICINE

The Treatment of Frostbitten Fingers and Toes —Dr Lapatin, in the *Proceedings of the Caucasian Medical Society*, advises that fingers and toes which have been slightly frostbitten, and which subsequently suffer from burning, itching, and pricking sensations, should be painted, at first once, and afterwards twice a day, with a mixture of dilute nitric acid and peppermint water in equal proportions After this application has been made for three or four days, the skin becomes darkened and the epidermis is shed, healthy skin appearing under it The cure is effected in from ten to fourteen days The author has found this plan very effectual amongst soldiers, who were unable to wear their boots in consequence of having had frozen feet They were, in this way, soon rendered capable of returning to duty —*Brit Med Jour*, Sept 5, 1885

SURGERY

Treatment of Joint Diseases by Rest and Fixation —Dr De Forest Willard thus sums up a paper read before the Lehigh Valley Medical Association, on August 19

1 Rest subdues joint inflammation more effectually than all other means combined, often aborting, always lessening, an impending process Its employment is indicated by nature, its beneficial influence is seen in every domain of medicine, in theory it is rational, in practice it fully proves its power

2 The more perfect the rest, the greater will be the diminution of pressure, friction, tension, and inflammation, and the less will be the resultant ankylosis and suppuration

3 The means for securing rest and fixation are exceedingly simple and can be applied by every intelligent practitioner

4 Counter irritation is of secondary importance

5 In inflammations of the sterno clavicular, acromio clavicular, and scapulo humeral articulations the arm should be fastened to the body which takes the place of a splint

In elbow disease the member should be immovably fixed in a semi flexed or in an extended position, pressure aspiration puncture, drainage, excision etc, to be employed as necessary

In the wrist and hand articulations the same principle is to be enforced, long continued rest being necessary Early exit of purulent accumulations must be secured antiseptically by the bistoury and the progress of caries carefully watched, the surgeon interfering only when nature is unable to properly accomplish separation or health fails

In the ankle and foot the same will hold true, fixation by plaster or other rigid material being complete and permanent Locomotion for even one step without the aid of crutches should be positively forbidden —an injunction which is equally applicable to diseases of the knee and hip

At the knee, the question of counter irritation, immobilization, or rest in bed with extension, will depend largely upon the amount of traumatism and the existence or absence of muscular rigidity When nature indicates by the last mentioned symptom that motion is harmful, delay in enforcing one of the latter measures is criminally negligent

Serous effusion should be aspirated, pus evacuated antiseptically, free drainage maintained, and excision practiced as soon as it is decided that destruction has occurred

Permanent rest and fixation, with the use of crutches, are far better than any form of extension that can be applied in the upright position

In hip disease, horizontal extension with fixation answers best for the acute stage, Three months after the cessation of pain, if deformity has been largely reduced, the erect position may be assumed provided the joint is put at rest by a fixation apparatus and the high shoe and crutches are used —*N Y Med Jour*, Dec 5, 1885

Cure of Varices by Excision —Mr J Farrant Fry, in an article on this subject draws the following conclusions If palliative measures afford sufficient relief, it is unwise to operate, but of the various operations, the excision of the vein is the safest and that, for its successful performance, the following details must be strictly carried out

1 Excise through several small incisions (not more than an inch in length) in preference to removing one large piece, as by so doing the vein is occluded at several points

2 Mark the site of the proposed excisions before applying the bandage, as the position of the varices becomes indefinite when the limb is rendered bloodless

3 Apply the Esmarch's bandage carefully, so as thoroughly to empty the blood vessels, or, the wound becoming full of blood, there will be considerable difficulty in dissecting out the vein, and very troublesome hæmorrhage may occur

4 Ligature the vein at its upper end, and dissect it out from above downwards

5 Remove as little as possible of the tissues surrounding the vein, but, if unavoidable, take also away the deep fascia (which is but feebly supplied with blood, and will not favor union), and allow the skin to adhere to the vascular muscle

6 Apply the dressings, and bandage the limb, before removing the tourniquet By this means hæmorrhage is avoided, and primary union encouraged

7 Above all, the careful employment of antiseptic measures is necessary, both during the operation and in the subsequent dressings —*Brit Med Journ*, Sept 5, 1885

Ligation of the Common Iliac for Aneurism —Dr D Ignacio Plasencia reports the case of a man, æt 34, upon whom he performed this operation on July 22 The ligature used was No 13 surgical silk The patient was well on September 5, and the tumor was reduced to the size of a small lemon, and was very hard —*Cronica Medico-Quirurgica de la Habana*, Nov, 1885

THE
Journal of the American Medical Association
PUBLISHED WEEKLY

The Editor of this Journal would be glad to receive any items of general interest in regard to local events or matters that it is desirable to call to the attention of the profession. Letters written for publication or containing items of information should be accompanied by the writer's full name and address, although not necessarily to be published. All communications in regard to editorial work should be addressed to the Editor.

Subscription Price, Including Postage.
Per Annum, in Advance $5 00
Single Copies 10 cents

Subscriptions may begin at any time. The safest mode of remittance is by bank check or postal money order, drawn to the order of the undersigned. When neither is accessible, remittances may be made at the risk of the publishers, by forwarding in registered letters.

Address,
Journal of the American Medical Association,
No. 65 Randolph Street,
Chicago, Illinois.

SATURDAY, DECEMBER 19, 1885.

THE EXECUTIVE COMMITTEE OF THE NINTH INTERNATIONAL CONGRESS.

In our issue of November 28, we showed how the Committee of Arrangements appointed by the American Medical Association to provide a Preliminary Organization for the Ninth International Medical Congress had, at its last meeting, so modified the Rules regarding membership as to obviate all the objections that had been made to those previously proposed, and had proceeded so far with the selection of general officers and the organization of Sections, as to bring into existence an Executive Committee of the Congress with powers, duties and limitations as provided in Rule 10, and had then transferred to such Executive Committee authority to make all further appointments necessary to complete the organization of the Sections, and to take charge of the affairs of the Congress. We reminded our readers, also, that the Committee on Organization, in framing Rule 10, providing for an Executive Committee to be constituted of the President, Secretary General, Treasurer and Chairman of Finance Committee of the Congress, and of the Presidents of the several Sections, authorized said Committee to elect such additional members as it might deem advisable, provided the whole number of the Executive Committee should not exceed thirty. This power conferred upon the Executive Committee to add to its own number within certain limits, was regarded as affording an opportunity for promoting a return of harmony and concert of action by electing to the Executive Committee a considerable number of the original leaders in the movement for a Congress in this country, who under other proposed rules and circumstances had declined to act.

The general officers and Presidents of Sections who were to constitute the Executive Committee of the Congress, after formally accepting their appointments under the Rules adopted by the Committee of Organization, assembled in New York, on November 18, 1885, and entered upon the discharge of the important duties that had been devolved upon them. After a free interchange of views it was decided to postpone the filling of all the more important vacancies in the organization of Sections, until such means for inviting cooperation and harmony of action as were within the control of the Committee had been fairly tried. Finding that the maximum number of the Executive Committee, as provided in Rule 10, permitted the election of six or seven new members, the Committee proceeded at once to unanimously elect Drs. William Pepper and J. M. Da Costa, of Philadelphia, Surgeons J. S. Billings, U. S. A., and J. M. Browne, U. S. N., Dr. Christopher Johnston, of Baltimore, and Dr. Geo. J. Engelmann, of St. Louis, as members of the Executive Committee. The last four named were selected partly because they were members of the original committee of invitation appointed in Washington, May, 1884, and partly because they represented important interests in the profession. The first two were selected because of the high official positions they occupied and the extent to which they were known both in this country and in Europe. And it was hoped that all the gentlemen named were capable of appreciating the importance of the object to be attained, and of personally rising above all mere individual considerations, so far as they might be supposed to conflict with the maintenance of the honor and interests of the whole profession. That each of the gentlemen appointed might know exactly both the limits of power and the numbers of the Executive Committee, a copy of Rule 10 was enclosed in the official notices to them, and also a statement of the fact that the filling of all vacancies had been postponed until their decision should be received.

Such was the course of the Executive Committee, acting within the limits of the powers conferred upon it by the Rules under which its members had accepted office and in good faith to all parties. Had these six gentlemen appointed accepted the positions offered, it is quite certain that the eminent men who were originally appointed Presidents of the three Sections having that office now vacant, would have cheerfully returned to those places, and if not, the places would have been filled by such as the new appointees on the Committee should name, and every desirable interest in the profession could have been harmonized within thirty days. But what has been the result? Let the following, which was received at this office in the form of a printed slip after THE JOURNAL for the 12th inst. had gone through the press, answer:

> THE INTERNATIONAL MEDICAL CONGRESS OF 1887.—A meeting of members of the medical profession interested in the International Medical Congress in 1887, to which prominent medical men from a number of cities were invited, was held at the Hall of the College of Physicians, Philadelphia, December 4, 1885, Dr. D. Hayes Agnew in the chair.
>
> It was stated that official notice had been given of the election, as members of the present Executive Committee of the Congress, of Drs. J. S. Billings and J. M. Browne, of Washington, D. C., Christopher Johnston, of Baltimore, George J. Engelmann, of St. Louis, and J. M. Da Costa and William Pepper, of Philadelphia.
>
> A general and strong expression of opinion was made in support of the American Medical Association and its Code of Medical Ethics, and sincere regret was expressed that hasty action on the part of the Association, and the introduction of false issues, had imperiled the success of the Congress.
>
> As an evidence of the earnest desire which is felt for the restoration of harmony upon this subject, and for the reorganization of the Congress on a basis which would command general support, and thus insure success, the view was unanimously expressed that if the present Executive Committee should unite with them the Original Enlarged General Committee, and recommence the organization *de novo*, this course would insure the desired result.

Following this in the *Medical News*, of December 12, is the announcement that all the six gentlemen have declined to accept the appointments. Instead of each individual weighing his own responsibilities and appreciating his own opportunities for promoting the welfare of the profession, and opening free correspondence with the Executive Committee for further information or possible changes, if any were needed, the whole matter is submitted to a partisan caucus for an evening of one-sided discussion, ending in a simple declination to accept. And this from the leaders of the party who claim to be the only eminent representatives of the science and art of medicine in America. Oh, Sense of Propriety, whither hast thou fled! The only suggestion accompanying the declination is, that the present Executive Committee shall unite or blend with itself the whole of the Original Enlarged General Committee, and "recommence the organization of the Congress *de novo*." In other words, that the present Executive Committee shall openly violate the tenth Rule, to which it owes *its own* existence, and from which it derives all its powers, then abrogate itself and attempt to leave the organization of the Congress wholly to that imaginary body called the Original Enlarged General Committee. We say "abrogate itself," because each member of the present Executive Committee holds such membership only by virtue of his appointment either as a general officer of the Congress or as President of a Section, and the moment he vacates such office to commence the organization of the Congress *de novo*, he ceases to be a member of the Executive Committee, and the way is open for the Committee of Arrangements, composed of one representative from the profession of each State and Territory, etc., to fill their places and resume control of the whole work.

We cannot believe that the six influential gentlemen to whom appointments on the Executive Committee were tendered either considered with sufficient care their own individual responsibility, or appreciated the real nature of the suggestion to which they lent their sanction. And we therefore warmly commend to their consideration the following paragraphs from an editorial in the *Medical News* of the same date as that containing the account of the medical caucus above mentioned. "The time has now arrived when honor rises superior to all other interests, and demands that we shall combine for international purposes, and make good the invitation which, in the name of the medical profession of this country, was extended to our brethren of foreign lands to hold their next Congress at Washington. Everyone who has had the true honor of his profession at heart, regardless of the mistakes that he thinks others have made, has looked upon the situation with feelings of deepest sorrow and mortification, and has felt that under the circumstances, any honorable sacrifice to avert the threatened disaster was a duty he owed to his profession and to his country.

We cannot but hope that the few who now have it in their power to effect this harmony will use their influence to that end, and by their action, under the present trying circumstances, show that they are ready to sink personal considerations for the public good. The occasion is one for the display of the highest patriotism, and the end to be attained is worthy of the greatest sacrifices." So thought the members of the present Executive Committee of the Congress, and so they have acted in the only direction within their power. And in the same spirit, we trust, they will continue to act in the prosecution of their work, and they cannot fail to be sustained by the great body of the medical profession, at home and abroad, until their work is crowned with that abundant success which, in the opinion of every impartial mind, it certainly deserves.

THE NEW ANTIPYRETICS.

However conservative the Germans may be in social and political affairs, there is no question as to their being progressive in medical matters. They are eager, restless investigators. Within the last two years synthetical chemistry in Germany has signalized itself by the production of several compounds which have been found to exert marked antipyretic power. Their names have already become familiar to the medical profession throughout the civilized world. Antipyrin, was derived from chinoline by L. Knorr, a chemist of Erlangen, and brought to the notice of the profession in 1884, by Dr. Filehne through the columns of the *Zeitschrift für klinische Medicin*. Kairin also was introduced into use in medicine by Filehne, while thallin was discovered by Skraup, and recommended as a febrifuge by Dr. von Jaksch, of Vienna. The rapidity with which their employment has spread among the clinicians of Europe and in this country is astonishing, and the literature upon the subject has already become extensive. Resorcin chinolin, brenzmatechin and hydrochinon likewise possess antipyretic virtues, but either by reason of associated disadvantages or inferior power are less esteemed than the three named above. Of hydrochinon, however, it must be said that Dr. Kinnicutt, of New York, has experimented carefully with this agent, and reported favorably upon it before the Academy of Medicine in that city. (See *New York Medical Record*, May 30, 1885.)

In the same city Dr. Van Schaick and others have been testing the action of inspissated ox gall, and claim that in doses of thirty grains or more it also acts as an antipyretic. Dr. Tovar, of Cuba, has lately announced that parthenine, one of the constituents of parthenium hysterophorus, a plant of that island, possesses febrifuge as well as antiperiodic power. The natives of Cuba use this plant as a substitute for quinine, and with the exception of salicin, salicylic acid and salicylate of soda, parthenine is the only one of the new antipyretic agents which, like the quinia salts, exerts specific power over fevers. Parthenine deserves further investigation.

Although the physiological action of antipyrin, kairin and thallin is not fully understood, it is well established that they do not depress the bodily temperature in health in doses which certainly lower it when elevated by disease. Brouardel and Paul Loye assert that kairin and thallin destroy the hæmoglobin and lessen the power of the blood in consequence, to transport oxygen and carbonic acid to and from the tissues. According to the same observers antipyrin does not exert this destructive action on the blood, but is nevertheless toxic in its effects, producing in poisonous doses tetanic convulsions, similar to those of strychnia poisoning. Unlike resorcin, these three agents possess no antifermentative or antiputrefying properties. Antipyrin, aside from its antithermic action, possesses hæmostatic virtues which Henocque pronounces superior to those of ergotine and chloride of iron.

Since these agents are all pronouncedly antipyretic, the query arises as to how they exert this effect? Filehne has expressed the opinion that it is through the nervous centre which regulates the production and loss of the animal heat, while Jaksch, Bettelheim and others have advocated the theory that it is due to a dilatation of the peripheral vessels in consequence of which a greater amount of blood is subjected to the cooling action of the external atmosphere. Some influence has also been attributed to the free diaphoresis which follows the exhibition of these drugs.

Another query concerning the effect of these antipyretics is, whether or not their employment is attended by danger or any contraindicating disadvantages. The general opinion of clinicians is that they are safe, sure and unobjectionable. Yet the reports made thus far ought to lead a conservative man to regard declarations concerning their safety as the expression of a too great enthusiasm. Almost all who have employed antipyrin and thallin have reported the occasional production of a subnormal temperature bordering closely on collapse, while May has narrated one case of actual collapse as the result of antipyrin. Dr. Barrs, of Leeds, has published one instance in which death occurred after, and probably in consequence of the administration of 35 grains of this remedy, followed in three hours by half that dose. Such facts as these should make one cautious, particularly in cases of adynamia. Vomiting and an exanthematous rash sometimes result, but seem not to be of grave import nor specially annoying. If, however, thallin and kairin exert the destructive influence upon the blood that is asserted by Brouardel and Loye, their employment should be prohibited. Moreover, the depressant effect of kairin is so great that, at the fourth German Congress of Internal Medicine, held at Wiesbaden last April, a strong feeling against its use was expressed.

The remedies under consideration have been employed in children as well as adults, and in a great number of diseases attended by high temperature. Antipyrin has yielded specially happy results in phthisis and typhoid fever. It is preferred to quinine as more efficient, and free from the cerebral disturbances which characterize the quinia salts Indeed, along with the reduction of the temperature in typhoid fever, there is produced a notable improvement in head symptoms On the whole, antipyrin and thallin are endorsed by high authorities, although, owing to their somewhat delayed action as compared with that of the cold water bath, it is generally thought best to resort to the bath in cases of alarming hyperpyrexia Indeed, the Vienna school appears to prefer cold water to mere medicinal antipyretics, and argues that the benefit of the bath is not limited to the mere reduction of the bodily heat Its action upon the skin, nervous system and kidneys must be taken into account, and in this lies a great part of its superiority over antipyrin or other medicinal febrifuges In this country the cold bath has not met a very cordial reception from either physicians or patients This is due largely to the discomfort and trouble involved

In the columns of The Journal of Sept 26, 1885, under the head of "Medical Progress," is a plan suggested by Dr H C Wood in the *Therapeutic Gazette* for July last, according to which a cold bath may be given quite easily He also expresses a preference for cold water as a febrifuge, over internal agents which are manifestly depressant, and we think the opinion of such an authority should carry weight He also mentions the declaration of Stephan, of St Petersburg, that the heat of the body can be reduced by the application of cold wet sponges to the neck over the superficial veins Those wishing a more explicit account of antipyrin will find in the columns of The Journal of Dec 5, 1885, a contribution, by Dr S S Adams, of Washington, upon its history and physiological effects In the same number, under "Medical Progress," Jaccoud's experiments with thallin are narrated, with a limited review of the action of this drug, antipyrin, and others of the series

SOCIETY PROCEEDINGS

AMERICAN PUBLIC HEALTH ASSOCIATION

Thirteenth Annual Meeting, held at Washington, D C, December 8, 9 and 10, 1885

(Specially reported for The Journal)

Tuesday, December 8—First Day

The Thirteenth Annual Session of the American Public Health Association convened in Willard's Hotel, Washington, at 10 A M , under the Presidency of James E Reeves, M D , of Wheeling, W Va Ninety five members were present

The President introduced Dr Smith Townsend, Chairman of the Local Committee of Arrangements, who announced the plans formed by the members of the Committee for the entertainment of the members

Dr Irving A Watson, of Concord, N H , Secretary of the Association, then read a communication from the Montreal Board of Health, regretting its inability to send a delegate

Dr A L Gihon, U S Navy, stated that it was necessary that a permanent

COMMITTEE ON INCORPORATION

should be established

Forty gentlemen were then elected members of the Association, and the names of twenty four proposed for active membership

Dr J Irving Watson, the necrologist, read the list of members deceased since the last meeting

Dr J Berrien Lindsley, of Nashville, submitted

THE TREASURER'S REPORT,

showing a cash balance on hand of $1,105 03

The Constitution was then so amended as to make the Incorporation Committee a standing committee

Dr Ezra M Hunt, of Trenton, N J read a paper on

SANITARY NOMENCLATURE

It carefully reviewed the various terms now used in sanitary, statistical and parasitical nomenclature Such terms as hygiene, contagion, infection, miasm, malaria, etc , were subjected to careful review, and their proper use designated The adaptations of the English nomenclature to new diseases were reviewed In the parasitic nomenclature of disease the terms micro organisms, microderms, microbia microzia, microphytes, microzyms, were discussed The classification of Cheyne was preferred The paper is important, as furnishing the basis of a careful and definite use of terms in the discussion of communicable diseases

Dr George H Rohe, of Baltimore from the Committee on Disinfectants, then presented the report of this Committee, which consisted of an elaborate monograph

Dr John S Billings, U S Army, read a paper on

METHODS OF TABULATING PUBLIC RECORDS OF DEATH

After referring to the fact that it is desirable that vital statistics should be published upon some uniform plan, which is at present not the case, he proceeded to define the wants of statisticians and sanitarians which are to be supplied by such tables, and for the sake of simplicity, considered first, the needs of the health officer of a city He desires information of the first appearance of any of those diseases which are liable to become epidemic, of the usual prevalence of any form of disease, of the localities of such prevalence, of the effects produced on health by certain occupations, manufacturing establishments, tenement houses, things which are complained of as nuisances, or by measures taken to effect improvement, such as the introduction of a general water supply, the construction of drains and sewers, etc In order that he may, from the statis tical records, determine where sanitary work is most needed, and whether the steps which have been taken to effect improvement have really been useful or not, he must have the information for individual localities, and sometimes for quite limited ones, as well as for the whole city This information, to be practically useful, must as a rule, be in the form of percentages or ratios, in order to permit of comparisons These ratios should be stated in terms of the living population, furnishing the sickness of deaths under consideration wherever it is possible to give this Hence, it is highly important to know the population of each of the units of area adopted

As a matter of fact, no health officer expects to be able to ascertain the number of cases of sickness in any locality, the best he can hope to do is to ascertain the general character of the prevailing disease, the number and location of cases of a few of the specially contagious forms of disease, and the number of deaths from each cause If he can obtain these promptly and accurately, he will be unusually fortunate, and from these data he can draw valuable inferences as to the amount and character of preventable disease existing in the community at a given time, and also as to the connection between certain forms of disease and death, and the circumstances of the environment, in order to know what diseases are preventable and how this prevention is to be effected

For the first of these purposes, he needs the results as promptly as possible—weekly bulletins are the usual forms in which they are given to the public For the second purpose, careful study of the facts in all their relations is necessary, and also the accumulation of a large number of facts, this requires time, and such studies usually appear in annual reports We have therefore to consider the best means for weekly reports which are essentially reports of warning, provisional and incomplete, and for annual reports which are intended to record the facts as completely as possible, and in the form most convenient for study, which, in other words, are to furnish the materials for vital statistics properly so called As the purposes of these two forms of reports are different, it is not wise to endeavor to combine them, that is, to make the weekly form so complete and elaborate that the annual report shall be little more than a summary of the weekly forms

The forms used in annual reports were then discussed and a table was given, showing for different States and cities the classification of data in regard to deaths given in their annual reports, showing great diversity in the forms used, and that also in many of the reports important information is wanting The important question to be answered by the statistician from the data of deaths and living population in each sanitary unit of an area, such as a ward, county, etc , is, how many persons of each sex, of each age, of each color, died from certain causes, and what is the proportion of such deaths to the number of living population of corresponding sex, age, and color in the same unit of area? It is by no means sufficient to give the total number of deaths of each sex, then of each color, then of each age, etc , even the binary combinations of these as shown in the table, are insufficient to furnish the information which is required to determine the nature of the influences which injuriously affect the health in a given locality Let us suppose, for example, that we are told that in the city of Washington the number of deaths from diarrhœal diseases during the year was much greater in ward 1 than it was in ward 2 The question is as to the cause of this difference This cause might be, first, some difference in the water supply of the wards, as for example, one might get its supply mainly from springs or wells, and the other from the general supply, or it might be due to defective sewerage in one of the wards, or to a greater amount of surface uncleanliness, or on the other hand, it may be due to differences in the character of the population of the wards, the one being inhabited largely by negroes, and the other by whites, or the one have a relatively large number of infants as compared with the other, or it may be due to poverty, producing overcrowding, and improper food supply Now to determine which of these causes has been more especially acting, and in what direction remedial measures are to be applied, we wish to know how many children of each color, black and white, there were living in each ward during the year, and how many children of each color of each year of age under five years of age died from diarrhœal diseases during the year From these data we can soon obtain answers which will narrow the field of inquiry as to the special causes of the prevalence of this form of disease in one of the wards, very greatly, even if we can not completely answer the question

A most important factor in mortality statistics is age Each age is specially liable to certain diseases and injuries, and upon the proportion of persons of certain age groups living, will depend to a considerable extent the general mortality rate, and to a still greater extent the mortality rates from special causes But to obtain from the age data of the dead, the full information which they can yield, it is essential to have the corresponding age data for the living population At present we can only get this with any degree of accuracy by means of an United States or a State census, that is for most places only once in ten years The so called "police censuses" which are taken from time to time in cities are, as usually managed, of little value in determining the number of living population, and give no information as to the age distribution except as to the number of adult males It would not be difficult, however, to obtain from a police census extremely valuable information, not only as to the total number of living population, but as to the number of infants under one year and of children under five years of age, with distinction of color and sex, and to do this with but little more expense and trouble than that required for the present imperfect methods, and this is a matter in which a health officer who is on good terms with the police authorities may effect a great improvement The practical objection to the preparation and publication of tables of vital statistics in the complete forms which I have indicated, is simply that they are expensive, requiring much more time and labor to prepare them, and much more expense for their publication, than do the collection and publication of the simple elementary data of which these compound tables are made up. In a city having twenty wards, the deaths in each ward during the year for each sex, and of each of twenty groups of ages, can be given on a page; if it is to be given for each group of age age for each sex, it will require at least twice this amount of space, and if a total is to be given, as well as that for each sex, it requires three pages. If we add the distinction of, say fifty causes of death, these for the twenty wards would give an addition of two pages. But if the number of deaths at each age, of each sex from each cause in each ward is to be shown, it will require three times fifty, or 150 pages to present this data distinctly.

With reference to methods of compilation, rapidity and accuracy can best be secured by the use of small cards, each one of which is devoted to data relating to an individual. Such cards can be readily distributed into any subdivisions which may be desired and then counted.

The weekly report is not published for the information of the health officer. It is for the information of the people, as a means of education, and for the creation and maintenance of an intelligent public opinion, of which sanitary officials have so much need, and in the absence of which their warnings and recommendations are too apt to be entirely unheeded. It also serves to fulfil a duty which the health officer owes to the sanitary authorities of other localities, viz. the giving them timely warning of any outbreak which threatens the public health. Considered as an educational document, it is very important that the lesson which it is intended to teach should be clearly set forth, and this not to be done by merely giving columns of figures. The significance of these figures should be clearly stated in words, and upon the manner in which this is done will greatly depend the usefulness of the publication. The best means of diffusing this information is through the daily and weekly secular press, which is always glad to obtain and publish it, if furnished regularly, promptly and in proper form. A good rule is to furnish it to the press every Saturday afternoon, closing the record at noon that day.

The chief points of interest for this report are the total number of deaths from all causes, with distinctions of sex, color, age and locality, the number of deaths from certain specified causes, if there is a system of registration of contagious diseases, the number of cases of each of these forms of disease with distinction of color, sex, age and locality, the number of births, with distinction of color, sex, age and locality, and certain ratios to permit of drawing comparisons. It is not desirable in these weekly reports to attempt to give the number of deaths from each individual cause, or from a large number of causes, and such an attempt is one of the most usual mistakes made in this work. The following are the causes of death which should be specified, and as a rule no others should be referred to in the report: Asiatic cholera, yellow fever, small pox, typhus fever, enteric fever, scarlatina, diphtheria, croup, measles, whooping-cough, malarial fevers, erysipelas, puerperal diseases, diarrhœal diseases (including diarrhœa, dysentery, cholera morbus and cholera infantum), cancer and tumors, phthisis pulmonalis, other forms of tubercular disease (including tubercular meningitis or acute hydrocephalus, scrofula and tabes mesenterica), pneumonia, other acute lung diseases, old age, childbirth, stillbirths, accidents, homicides, and suicides.

The units of area for which these are to be reported should, as a rule, be the wards of the city, but to this rule there should be some exception. In the first place, it sometimes happens that the ward lines are fixed for purely political purposes, enclosing extremely irregular areas, having no relation to topography. This, for instance, is the case of the present wards in the city of Baltimore. In such a case the ward divisions are absolutely useless for the purpose of the sanitarian and statistician, and should be abandoned; the health officer making his own divisions in accordance with the topography and the character of the population. In such a case he should endeavor, when a census is taken, whether this be done by the city, State, or United States authorities, to have the results of such census furnished him in a form corresponding with the divisions which he has adopted.

It is often desirable for special purposes in certain localities, and for a short time, to make use of smaller units of area than the ward, that is, to give the number of cases of, and deaths from, certain diseases in a certain square or block, or in the vicinity of certain slaughter-houses, hospitals or other establishments which may be suspected of exerting deleterious influence on the public health, and in some cases the publication for a few weeks of the death record of a particular tenement house or foundling asylum, will interest the public and have a good effect.

Some of the weekly forms of reports actually employed by different cities were then shown and commented on. The summary of the weekly writings issued by the Registrar General of England was pointed out as a model for such writing. The weekly bulletin of the City of Brussels, issued by Dr. Jansens, was also pointed out as a model. It was advised that the weekly report, as a rule, should be published by giving it to the daily press, and that the separate bulletin had better be in a monthly, rather than a weekly form. Statistical reports of disease, or mortality statistics, can, as a rule, only be obtained for a few of the contagious or spreading diseases, with regard to which compulsary notification is enforced. The exception to this rule occurs in the army and navy and in the police force of some cities, where all cases of excuse from duty are recorded, with the cause of the exemption. The reports of prevailing diseases published by the Michigan State Board of Health, are statistics of the opinions of physicians as to the relative prevalence of certain forms of disease, and not of the actual number of cases. Where there exists in a city a system of compulsary notification of cases of contagious and infectious diseases, the number of cases of each kind of disease should be reported weekly with distinction of sex, color and ward, and of age. There are sometimes great difficulties in the way of doing this owing to the pressure which commercial interests exert upon the health authorities or Registrar, and on the public press, to prevent the publication of what seems likely to injure the business interests of the city Unless one has had some personal experience of the intensity and magnitude of this sort of pressure, he can not estimate the difficulty of resisting it Nevertheless, the attempt to conceal the extent of prevalence of an epidemic in a city is always a short sighted policy, because it always gives rise to exaggerated rumors as to the amount of disease present, and thus really tends to increase rather than to allay panic in neighboring communities Moreover, when it is discovered that a health officer has attempted to conceal this kind of information in one instance, he becomes an object of suspicion to other sanitary authorities, and his statements though truthful, are not believed I think his wisest course in all cases, is to furnish the press with full, accurate, reports of prevailing sickness and deaths so far as he has the data to do so, and thus avoid the responsibility of concealment

There are several sources of information with regard to the amount and character of disease prevailing in a city of which the health officer can with a little tact and management avail himself, and which it seems to me are too much neglected There are the public dispensaries and other institutions for the treatment of the sick, including the city physicians to the poor, the prisions, reformatories and asylums, and the public schools From all these, certainly from all of them which are supported from the public funds, he should be able to obtain reports showing the amount and character of the diseases coming under their notice

In conclusion attention was called to the importance of the use of graphic representations of the results of studies of vital statistics to be given in the forms of diagrams and shaded maps While such illustrations are somewhat costly and in one sense add nothing to the information derived from the tables from which they are compiled, they are an extremely important means for the diffusion of this knowledge, for educating the people as to the value and uses of vital statistics—and such education is now of prime importance to all who are interested in sanitary matters—it is in fact, a necessity if we are to make substantial progress in preventive medicine

Dr Henry B Baker, of Lansing, Mich , read a paper entitled

NOTES ON THE RELATIONS OF RAINFALL AND WATER-SUPPLY TO CHOLERA

He distributed copies of a table exhibiting the monthly mortality from cholera in Calcutta during the past twenty years, also diagrams showing the relations of rainfall to cholera One diagram included records of the monthly rainfall in Calcutta for forty-eight years, and statistics of over 600,000 deaths from cholera in the endemic area about Calcutta A striking relation of rainfall to cholera was shown to exist at almost every reason of the year, and he offered in explanation a probable reason for the apparent want of relation at the exceptional time, which is about the coldest season being briefly, that not so much water is drank at that season, and therefore there is less opportunity to contract cholera by the use of bad water, and especially as at such times some of the tanks and other objectionable sources of water are entirely dry

Dr D E Salmon, Chief of the Bureau of Animal Industry, read an interesting paper on

THE VIRUS OF HOG CHOLERA

He briefly referred to the wide dissemination of this disease, to its fatality, and the heavy losses annually occasioned by it in almost every locality in each of the States and Territories, and while it has never been shown that the malady may be transmitted to man, there are many reasons why it is deserving of profound study, by all who are interested in questions concerning the public health The number of hogs which die of this disease in this country annually reaches into the millions, and some disposition must be made of the carcases That disposition *may* be a matter directly bearing upon the health of our people Often these carcases are left to putrefy in the open air, or to be preyed upon by carniverous animals and birds, sometimes they are thrown into the ponds and streams which furnish drinking water to our cities, sometimes the lard is rendered from them, and what finally becomes of this product is an interesting subject for speculation Occasionally they are burned or buried, but only occasionally When this plague breaks out in a herd, the owners of swine in the vicinity often commence to ship their animals at once to escape its ravages, As a result, the disease is found in the great central stock-yards from which thousands of animals are taken every day and killed for packing Some of these have undoubtedly been infected and are passing through the incubative stage of the plague, in others the disease may be developing, and with the most careful inspection would pass unnoticed What would be the effect of the meat from such animals upon human health? Perhaps none of us can answer this question satisfactorily The flesh of diseased hogs may be practically harmless, or it may be the cause of some of the obscure maladies which the physician daily meets in practice To solve these problems definitely, it seems evident that one line of investigation must deal with the virus itself, its nature, its effects upon other species of animals, the period during which it retains its virulence after the death of its host, the durable chemical substances which it may form, and last, though not least, the septic complications which may accompany it

The study of this virus is also of peculiar interest to us, because of its bearing upon the general subject of contagion The science which treats of this important class of phenomena is still in its infancy A decade has scarce passed since Koch laid a substantial foundation for the germ theory of disease in his studies of the *bacillus anthracis*, the germ of malignant anthrax or charbon But charbon is not a virulently infectious malady The virus seems to multiply in certain soils, and is taken into the system with the food This disease is rather an endemic than an epidemic or epizootic Of the great epidemics, but few if any of the germs from which they arise have been satisfactorily determined. Fowl cholera is an example of an animal plague which is in no apparent degree limited by conditions of climate and soil. While epizootic, it seemed, after a long series of experiments, that the virus was not disseminated through the air, but that it was necessary for it to be ingested into the food or inoculated into the tissues to produce the malady. While this affection is caused by a micro-organism, we still lack an example of a virulently infectious disease caused by a bacterial organism, the contagion of which is disseminated through the atmosphere and when inspired with the air infects the animal. That hog-cholera is thus disseminated appears to be accepted by all who have studied it.

The isolation of the micro-organism which produces the disease, and the demonstration of its pathogenic action has been a most difficult task. For seven years this study has been constantly going on in Europe and America; the most competent investigators in this line of work have devoted their attention to it; every method that the latest developments of science have suggested has been applied to the problem, and yet, when the impartial reader approaches the subject and attempts to reach a conclusion from the literature attainable, his first decision will undoubtedly be that bacteriology is anything but an exact science.

The virus has been described under many different forms, and the speaker had not found, in connection with any other subject, so much of apparently scientific and convincing evidence which leads to so many different conclusions.

Dr. Klein described a micrococcus in 1876 without attributing pathogenic properties to it. In 1878 he stated that the cause of the disease was a bacillus which grows in long leptothrix filaments and forms spores. His inoculation experiments in most cases failed to produce severe disease with cultivated bacilli. Recently he described a different bacillus, which does not exceed five micro-millimetres in length, as the cause of the malady. This germ kills pigs, mice, and rabbits, but does not affect pigeons.

In 1880 and succeeding years the speaker found a micrococcus in a number of outbreaks. This germ was cultivated, and when used for inoculation produced disease. The effects were variable and the virulence was soon lost by cultivation. Further investigation showed that, in the advanced stages of the malady, it was complicated with septic infection and several different organisms could be found in the tissues. This made it necessary to discriminate between septic germs and the essential virus.

By studying each species of germs separately a very virulent bacterium has recently been discovered, which produces a disease in pigs having all the characters of swine plague, and kills mice, rabbits and pigeons. This bacterium is easily found in very acute cases, but in chronic cases the septic infection becomes more prominent and masks it. It remains to be determined if the outbreaks in other parts of the country are caused by this organism.

In 1883, Pasteur stated that the cause of *rouget*, believed to be identical with hog cholera, was a dumb-bell shaped microbion, which killed pigeons and rabbits, and which might be attenuated and used as a vaccine to prevent this malady.

Scientific men have been surprised to find that the active principle in the *rouget* vaccine now sent out by Pasteur is a fine bacillus, and an entirely different germ from that described in 1883.

Dr. Loeffler has studied the *Rothlauf* of Germany, believed to be the same disease as *rouget*, and finds it caused by a fine bacillus apparently identical with that in Pasteur's vaccine. The period of incubation of *Rothlauf* is much less than that of hog cholera, and there is an absence of that ulceration of the intestines which is the most characteristic lesion of the American disease.

Pasteur's vaccine had been tried. Its effects were not uniform or reliable. Of four pigs vaccinated with first vaccine, one died; the others showed no effects. The three remaining animals were treated with second vaccine, and a fourth was placed with them, which received a very large dose, about a drachm, of this. None of these were affected. They were then exposed to hog cholera and three of the four contracted the plague and died.

It is not considered possible that the fine bacillus described in France and Germany is the cause of our hog cholera, as it has never been found in the spontaneous cases here. It was, however, easily demonstrated in the body of the animal that died of Pasteur's vaccine. It was concluded, therefore, that this vaccine could not prevent the American swine fever, but might be the means of introducing a different disease that would increase instead of diminishing our losses.

(*To be concluded.*)

CHICAGO MEDICAL SOCIETY

Stated Meeting, November 16th, 1885.

The President, C. T. Parkes, M.D., in the Chair.

Dr. J. M. G. Carter, of Waukegan, read a

REPORT EMBODYING TWO HUNDRED CASES OF TONSILITIS

After detailing the treatments which had been employed in the cases, the author advanced the theory that since the great majority of the cases occurred during March, April and May, when northeast winds prevailed, carrying landward more moisture from Lake Michigan, these winds must be one of the causal factors in the production of tonsilitis. Also, the test for ozone during these months showed a greater percentage of ozone in the atmosphere. Another fact was noticed, that a great many cases occurred in rheumatic patients. The author was of the opinion the epidemic of cares detailed was due to the damp northeast winds, containing an excess of ozone, and to unusually disturbed electrical conditions of the atmosphere. The author grouped the two hundred cases, without classifying them, into cases of simple, diphtheritic or scarlatinous tonsilitis. He mentioned, however, the fact that simple tonsilitis were often accompanied or followed by attacks of diphtheria or scarlet fever among other members of the family

Dr F O Stockton said that we have tonsilitis in nearly all the eruptive fevers, usually following, and occasionally preceding them The author refers to cases having diphtheritic patches on the tonsils, I think he has confounded these diphtheritic cases with what specialists call follicular tonsilitis It is not a diphtheritic condition at all, but resembles it very greatly, so that in a differential diagnosis these cases are very often confounded In regard to the temperature going up to 104, it is my experience, and that of authorities such as Cohen, Bosworth and Robinson, that it ranges from 102 to 103, seldom more than 103, usually 102 In the treatment of tonsilitis I have never found a gargle effective In diphtheria or acute tonsilitis we may give chloride of potash, or any other drug, but when a man has a pain in the angle of his jaw and a throat so sore he cannot swallow, he cannot gargle Ice held in the mouth until it dissolves is good, also powder or tincture of guaiac and tincture of aconite internally, but more than three doses of aconite should not be given in one day Occasionally, a case is going on to suppuration, use hot applications externally and internally in the way of steam, otherwise never use hot applications My idea is that heat promotes congestion more than cold, and my experience is that where cases are treated, some with cold and others with hot applications, that the cold in connection with other treatment, guaiac and tincture of aconite, is most successful We ought to settle this question of tonsilitis What is acute tonsilitis, and is there such a thing as acute tonsilitis? To me it is a misnomer The abscess seldom forms in the tonsil, it is behind it in the loose connective tissue, and in opening it we cut behind or above the tonsil

Dr C W Earle asked Dr Carter if there was any appearance of contagion in any of the cases?

Dr Carter said that frequently the disease will attack everybody in the family, old and young, and just as frequently but one or two in the family have the disease It sometimes appears to be contagious

Dr G C Paoli said that tonsilitis is a very common disease in Chicago, especially among children It is certain that there are different degrees of tonsilitis, there are light cases in which very little medicine is required, and again there are strumous children who are very susceptible to the changes of weather, and in inclement weather get wet and have tonsilitis In some cases one tonsil is affected, in others both, or the pharynx There are grave cases that cannot be cured in one week, or two, cases that develop into hypertrophy of the tonsils In regard to treatment, a light case does not require ice, and a person with malignant scarlatina with tonsils affected would take cold from the application of ice We should discriminate, and in malignant cases when the tonsils are inflamed should be careful about applying ice In the use of aconite with children we should be very careful, as in fever it diminishes the circulation, and I would not recommend its general use unless you can see the patient two or three times a day and watch the effect of the aconite A simple thing to use is a little potash with tincture of iodine In scarlatina complicated with diphtheria it is better to use very little medicine I have nothing against chlorate of potash, but I have read a very interesting paper by a professor in New York, whose name I do not now remember, who says that observation has shown that chlorate of potash has often produced nephritis, and I think great care should be taken in its use

Dr R Tilley said that one of the points brought forward by the author is the use of kerosene Besnier, a professor of skin diseases in Paris, says that kerosene is used extensively by the laity, but he regards it as a dangerous remedy in the hands of people generally, and a very inefficient one, he was speaking, it is true, of treatment of itch He protested against the use of the terms ozone and electrical conditions of the atmosphere, we know practically nothing about either

Dr W E Quine said that an interesting feature of the experience embodied in the paper is the obvious failure of the writer to differentiate infectious from non infectious tonsilitis I presume it is a matter of familiar observation to all who have been long engaged in the practice of medicine that many cases of follicular tonsilitis occur which baffle the judgment of the most experienced physician to determine with precision whether they are infectious or non-infectious I have often seen in my own practice cases of this kind Often one member of a family, probably the first one attacked, exhibits plainly marked features of simple follicular tonsilitis, and those of the family who sicken afterwards exhibit the phenomena of diphtheria, or less frequently, scarlatina The text-books do not give a reliable guide to diagnosis, and if any of my colleagues know of means by which cases of this kind can be differentiated with certainty we would like to know them Jacobi in a recent article maintains very vigorously that many cases of so called tonsilitis are in reality immature cases of diphtheria, and he stoutly maintains that there are many cases of diphtheria never having patches in the throat, and the patient walks on the street and communicates the disease freely to those with whom he comes in contact

Dr Sarah Hackett Stevenson said that in February, 1885, she was called to see a lady who had frequently suffered from tonsilitis She was "subject to quinsy" I suggested that her child should not be kept in the same room with her, as the case seemed more than ordinary violent, and gave the usual treatment for quinsy, the disease went on to suppuration I was called out of the city after one of the tonsils had discharged, and during my absence, about five days, her child was attacked with malignant scarlet fever, and died before my return This is the first case in which I ever suspected that a benign form of tonsilitis might reproduce a malignant form Since then I have watched all cases, however simple they may seem

Dr C T Fenn said that he thought to regard these cases all as malignant is to be on the safe side A case of simple tonsilitis has a tendency to develop into diphtheria He protested against the folly of attempting to distinguish between mild and simple cases of tonsilitis and diphtheria. In regard to treatment, he has no use for gargles or washes, he will not force open the mouth of a child and cause it to cry, but steadily and persistently, every fifteen minutes, he gives such medicines as the child will carry over the tonsils when swallowing.

Dr. J. S. Knox regretted that the paper was so general, the author evidently grouping together a variety of cases of tonsilitis of different classes. There is undoubtedly an inflammation of the tonsils due to eruptive diseases, such as small-pox and scarlet fever, and there is a tonsilitis which is purely catarrhal, and another which is purely due to diathesis and which is rheumatic or syphilitic. The treatment differs accordingly. He thought there is an error as to the value of chlorate of potash, better results will be obtained from the use of bicarbonate of potash, the value of the drug lying in the fact that it is a potash salt, and I think that the bicarbonate of soda would be still much more efficient. Where the hyposulphite of soda would do good, the salicylate would do more.

Dr. J. J. M. Angear thought that if we remember that there is such a thing as resistance, the absence of which is susceptibility, it will explain some, if not all of these difficulties. We can readily imagine a robust, healthy child with strong resistance to morbid influences, and especially that of diphtheria, on exposure, would have simple tonsilitis (abortive diphtheria), but suppose that his brother, with strong susceptibility, is exposed to the same morbid influences, he will develop a case of undoubted diphtheria.

In diphtheria, we have an inflammation with fibrinous exudation which breaks down the mucous cells and forms the diphtheritic patch, this furnishes a nidus for the micro organisms, which go on secreting or fermenting their peculiar virus, the absorption of which contaminates the whole body, and now we have a constitutional disease. Will not this explain a large number, if not all, of those cases where four or five children in a family are taken down apparently with simple tonsilitis, and some one child that has not their resistance is attacked with undoubted diphtheria. In this house we have tonsilitis, and our neighbor severe diphtheria. By remembering these pathological facts, we shall see that it is, or may be, all the same morbid influence here and yonder—here, recovery in a few days, there, death in a few hours.

Dr. F. O. Stockton said that in acute tonsilitis he thought it will be found that ice is the proper treatment in the first stage, before suppuration has begun. It is very seldom that pus is located in the tonsil, it is behind the tonsil. With regard to a differential diagnosis between diphtheria and tonsilitis, there is almost always in diphtheria a regularly graded rise in the temperature, in acute tonsilitis, so called, or follicular, the temperature is not regular, it rises at a jump, the attack comes on suddenly, begins with a chill immediately followed by fever, in diphtheria there is a gradual rise, going up one day, dropping the next. He thought if we took a record of given cases of diphtheria and tonsilitis, we should find that a regular rise in temperature in diphtheria occurs in the essential fevers.

Stated Meeting, December 7, 1885.

THE PRESIDENT, CHAS. T. PARKES, M.D., IN THE CHAIR.

Dr. E. F. Wells, of Minster, Ohio, read a paper on

PNEUMONIC ABSCESS.

(See p. 675.)

Dr. Christian Fenger said that an interesting point in the paper is that the author takes the ground of the clinical and, perhaps, conservative man. Dr. Wells claims that we should not operate on the small abscesses, but only on large ones, as the latter are the more dangerous. Dr. Fenger believed that we should operate on all of them when indicated. Buhl, in Christiania, has operated on nineteen cases in which there were cavities. Up to the present time, we have reports of about thirty cases in which operations have been performed, but only seven of these cases have been such as reported by Dr. Wells, or abscesses incident to pneumonia. Since there have been only seven cases of abscesses of the lungs, incident to pneumonia, it stands to reason that these cases were severe ones, and that the abscesses were large. Dr. Fenger did not believe there had been much operating on small abscesses as yet, however, he would advocate it in case these abscesses were accompanied by a fetid bronchitis. There is an abscess cavity, which Rokitansky calls a chronic abscess, in which there is not connective tissue enough to allow the cavity to close. This cavity is a source of danger to the patient, as sometimes, for one reason or other, septic micrococci gain entrance, acute inflammation or gangrene follows and the patient dies. In such a condition, we should try to obliterate the cavity. Operative treatment of these abscesses has been so infrequent that we cannot say that it possesses any advantage over medical treatment. The important point to be decided in the future is how to get an understanding of where the danger-line is, how long we can afford to wait and how much strength can we afford to let the patient lose before we operate? It is, perhaps, well to put in a word of warning against operating too early, as we are all aware that patients who recover without an operation do better than those on whom there have been operations. Dr. Fenger said that, in case a cavity gives rise to fetid breath, frequently a fetid bronchitis is developed, and subsequently an inter lobalular pneumonia in the other lung, or in the upper part of the lung in which the abscess exists. Relative to Dr. Wells's remark that he never suppresses the cough, Dr. Fenger stated that it is a fact that the cough ceases almost instantly after the abscess is opened.

Dr. R. Tilley said that he could not see of what benefit inhalations of turpentine could be in such cases, as the abscesses are analogous to those which occur in the more external portions of the body, and we never expect to benefit them by using turpentine. He would expect better results from administering this medicine internally, as he had, recently, read that the German physicians are using turpentine very successfully, by giving it internally, in diphtheria.

Dr. Wells, in closing the discussion, said that he wished to recall the attention of those present to the important point that these abscesses occur most frequently in the lower lobe of the lung, similarly to pneumonia. The principal object of his paper was to do what he can to counteract the tendency among the medical journals to advise early operation in pulmonary abscesses. He thought the statistics, so far, do not prove the operative treatment to be superior to the expectant and medicinal treatment, and he thought surgeons were too prone to take the cases into their own hands, and that they do not leave enough to the *vis medicatrix naturæ*.

MASSACHUSETTS MEDICAL SOCIETY—SUFFOLK DISTRICT.

SECTION FOR CLINICAL MEDICINE, PATHOLOGY AND HYGIENE.

ALBERT N. BLODGETT, SECRETARY.

Meeting of November 11, 1885.

FREDERICK I. KNIGHT, M.D., IN THE CHAIR.

(Concluded from page 668.)

DR. VINCENT Y. BOWDITCH read a paper on

A CASE OF PHTHISIS WITH BACILLI, COMPLETE ARREST OF THE DISEASE.

(See page 654, JOURNAL of December 12.)

DR. HENRY I. BOWDITCH, stated that practically he had for many years considered consumption to be a contagious disease under certain conditions. He always advises husband and wife to sleep in separate beds, and he much prefers them to occupy different rooms. There is no longer a reasonable doubt that the bacillary organisms found associated with tuberculosis have the power to produce that disease. The many and careful series of experiments so extensively performed and reported in Europe, are convincing upon this point. The main question now seems to be this: What influence does the presence of bacillary organisms exert upon our opinions in diagnosis and in prognosis? Where do we stand in relation to these bodies in the actual treatment of tuberculous diseases? When the bacillus was first discovered in connection with tuberculosis we were inclined to look upon its presence as a sign of the gravest significance. These first opinions are at present undergoing a modification as we observe cases in which the undeniable presence of the bacillus is not necessarily followed by a fatal course of the disease.

The case reported at this time, as well as others recently published, show that we need not feel entirely discouraged when bacilli are present, and conversely, we should not be so highly encouraged when they are absent. We do not yet know the absolute value of the entire relation of the bacillary organisms to the course or termination of diseased conditions, nor their full bearing and influence upon diagnosis or prognosis.

DR. KNIGHT said that he had seen a case in the early summer of 1884, in consultation with a practitioner of a neighboring city, in which the symptoms were quite acute, and in which the fears of rapid future progress were increased by finding numerous bacilli in the sputa. Contrary to expectation, however, the patient, who was a young lady, soon began to improve, and at last accounts had no cough, considered herself well, and had every appearance of being so.

Dr. Knight said that such cases in reality only confirmed what we know before, that is, that arrest may take place in pulmonary tuberculosis. Perhaps hitherto, in cases of arrest, we have been inclined to doubt the tuberculous nature of the disease. We can no longer feel this doubt.

DR. CUSHING stated that the higher degree of infectiousness of tuberculosis among animals who were subjected to experiment was no doubt due in some measure to the fact that the healthy animals are frequently placed in pens which have been occupied by diseased animals, and that quite possibly the cages themselves may contain the germs of tuberculosis and thus render the animals confined therein more liable to tuberculosis. It is a very suggestive fact that in the experiments to determine the infectiousness of tubercle germs when suspended in vapor, the spray was conducted out of the building in which the laboratory was situated, to cages some feet away, and the windows and doors of the laboratory were kept carefully closed during the experiment. Every one of the animals thus exposed to the tuberculous spray became affected with general tuberculosis. This fact should be a sufficient indication for all possible care in averting contagion in the human tuberculosis. The disease is clearly to be classed not only as communicable, but as a highly infectious one, and should be treated as such.

STATE MEDICINE.

THE POWERS OF THE ILLINOIS STATE BOARD OF HEALTH.

Judge McAllister recently delivered the opinion in the case of Lucas R. Williams against the people and others. Williams was indicted in the criminal court for the alleged violation of the act regulating the practice of medicine in Illinois. He pleaded guilty, was tried, convicted, and sentenced to pay $50 fine. He appealed the case upon the claim that he graduated at Rush Medical College February 16, 1875, while the act was passed May 29, 1877, and that consequently the act did not apply to him. The Board of Health granted him a certificate after the passage of the act, but subsequently, in 1880, revoked it. The appellate court reverses the judgment of the court below and remands the case. It holds that the statute of 1877, being penal, must be construed strictly. The State Board of Health was not a judicial body, and its powers did not exceed those conferred in the act. Under it its only powers related to those physicians having diplomas and those having none. As to the former, its only duty was to verify the respective diplomas and identify the persons claiming them. As to non graduates the Board had unlimited power. The right of the Board to re-

cases of tonsilitis
ment, he has n who had certifi-
not force op Williams had a diploma,
cry, but st no right to revoke his certificate
utes, he could not have intended to invest

THE PENNSYLVANIA REGISTRATION LAW,

Section IV of the Pennsylvania registration law of 1881, requires that diplomas outside of the State must receive the endorsement of a recognized Medical Faculty within the State before registration, but before giving such, the Faculty must be satisfied as to the qualifications of the applicant, and as the endorsement of a diploma is an acknowledgement of the qualifications of its holder as well as of its genuineness, the Faculty of the Medico-Chirurgical College of Philadelphia desires to announce that it will endorse no diploma for registration until the holder thereof passes a satisfactory Medical examination The fee for such examination is $30

requisites (1) To hold the fragments firmly in apposition (2) To allow the forearm to be flexed and extended, pronated and supinated (3) To lengthen or lessen the external angle of the arm with fixation (4) To leave the entire elbow joint exposed for the purpose of making local applications during the whole time of wearing the splint, without disturbing the latter Such an apparatus he had accordingly devised, and it consists of two rods of untempered steel, with ball and socket joint, and fixation screws at the elbow and wrist, the rods being secured to the arm and forearm by means of plaster-of-Paris bandages

At this meeting Dr Agnew presented a resolution, which was unanimously adopted, to the effect that, in the opinion of the Academy, any judicial action which tends to prevent the early reporting to the Board of Health, on the part of the medical profession, of cases of contagious disease, is contrary to public policy and detrimental to the public health This had special reference to the recent case of Brown vs Purdy, in which the Drs Purdy were fined $500 because a patient of theirs was sent to the small pox hospital by the sanitary authorities to whom they had reported the case, the plaintiff claiming that she did not have varioloid, as asserted by the physicians, and asking for $10,000 damages Unless medical practitioners can have some guarantee that they are not liable to such prosecutions as this, the number of contagious diseases reported in this city is likely to be uncommonly small for some time to come

At the same meeting a communication was read from the Health Department, announcing that the New Willard Parker Hospital, in East 16th St, is now open for the reception and treatment of cases of contagious disease, and inviting the President and Fellows of the Academy to visit it and inspect its accommodations It is provided with a resident physician and a corps of trained nurses, and is designed for the treatment of patients suffering from such diseases as scarlet fever and diphtheria, who cannot receive proper care in their own homes

General Alexander Shaler, the President of the Board of Health, has been charged with bribery as a member of a commission to select and purchase for the city three sites for armories for militia regiments, and required to furnish bail to the amount of $10,000 On account of his honorable record as a soldier and a citizen, and the high esteem in which he has always been held in the community, it is to be hoped that the General will be able to fully clear himself of these
ave accusations against him It is doubtful, how-
ever, w ther the administration of the Health De-
m as been as efficient under his management
hat of his admirable predecessor, Prof
handler At the same time, the expenses
ent have been considerably greater
Chandler was at its head Thus, a
Col Emmons Clark, the Secretary
Health, in explaining the routine
latter before the State Senate
ttee, showed that soon after
President he put his military
dividing the working corps of

the Department into seven divisions, each under the direction of a chief at a salary of $3,000 a year, thus causing an increased annual expenditure of $21,000 for work which was formerly attended to by the Sanitary Superintendent, Dr. Day, who is still the Executive officer of the Board, and to whom all the chiefs of divisions are responsible. It was also shown that there was greatly increased expenditure for clinical service.

Six children in Newark, N. J., were bitten by a rabid dog while on their way to school on the 2d of December. On the following day Dr. O'Gorman, of that city, published a card advising the parents of the children to send them to Paris to be treated by Pasteur, and asking for a public subscription for the transportation of those whose parents cannot afford the expense. At the same time, he cabled to the great French savant, inquiring if he would take charge of the cases if they were sent to Paris. On December 4 Pasteur replied that he would do so, and accordingly four of them are to be sent, a sufficient amount of money having been subscribed to ensure the payment of their expenses. A consultation of physicians has been held at the office of Dr. Herold, President of the Newark Board of Health, in regard to the matter, and it is probable that Dr. Frank S. Billings, of New York, will accompany the children to France, and make a study of Pasteur's methods with a view to introducing his prophylactic treatment of hydrophobia into the United States. The parents of two of the bitten children refused to allow them to go.

The first human body was successfully incinerated at the new Mount Olivet Crematory at Fresh Pond, Long Island, December 4. It was that of an Austrian formerly living in this city, but who had of late resided in Hoboken, across the river. He died about a month previously, and had especially requested that his remains should be cremated. The whole crematory building is not as yet by any means completed, but the incinerating apparatus has been put in working order. The structure is of brick and marble, and the architecture is a modification of a Greek temple. About forty bodies are now awaiting cremation here. Mr. Erastus Winan has just purchased a farm on Staten Island, on which another crematory is soon to be erected.

One of the dangers from large cemeteries has just been illustrated at the village of Nyack, on the Hudson. For some time past there has been a growing feeling among the inhabitants that the water courses running towards the village might become polluted by the increasing number of bodies buried in the Oak Hill Cemetery, near its northwestern portion, and recently the State Board of Health has been asked to make a full investigation of the matter. This has now been done, and the reports of Dr. Alfred L. Carroll, Secretary and Executive Officer of the Board, Horace Andrews, civil engineer, and William Halles Jr., who made the analyses of the water in the vicinity of the cemetery, which have just been made public, clearly point out the danger from this source, and at the same time make such suggestions as will lead to the obviation of the difficulty as far as possible. In the course of his report Dr. Carroll says "The dangers arising from decomposition of animal matter in burying grounds vary with the character of the soil, but under any circumstances the difference is rather one of degree than of kind. In porous soils such decomposition takes place most rapidly, complete decay of the body sometimes occurring in a very few years, but these soils permit the greatest diffusion of gaseous and dissolved products. In the case under consideration, with gravelly superficies underlaid by almost impervious strata, such wide diffusion of the rapidly produced liquefied results of putrefaction would be particularly favored. It has long been a matter of common experience that low fevers and various forms of 'filth diseases' are apt to prevail in the neighborhood of old burying grounds where population gathers around them." P. L. P.

BOOK REVIEWS

FACE AND FOOT DEFORMITIES. By FREDERICK CHURCHILL, C. M., Surgeon to the Victoria Hospital for Children. With Illustrations of New Appliances for the cure of Birth-mark, Club foot, etc. 8vo, pp. xvi, 195. Philadelphia P. Blakiston Son & Co., 1885. Chicago W. T. Keener.

The reason for combining so diverse topics as are indicated in the title of this book will be found in the author's own words in the preface, as follows "It may be asked why I should associate the face with the foot, as these are the two extreme parts of the body? Chiefly because deformities of these members of the body being more manifest than deformities elsewhere, they constitute a greater hindrance to success in life. They not only deform, but deface by reason of their great disfigurement, the artistic proportions of those parts of the body upon which the eye of the observer most loves to rest."

This short excerpt explains, so far as need be, the meaning of the alliterative title, "Face and Foot," and serves at the same time as a fair example of the writer's very defective and unpleasing literary style. But while his sentences are far less skilfully framed than those which lend a charm to the writings of Jonathan Hutchinson and others of our best medical writers, he nevertheless has much of value to tell in this book about nævus and club foot, the two affections with which it is chiefly concerned. It is to be noted that the comparatively new and highly successful practice of treating nævi by the needle cautery and perforated metallic plates, is here for the first time adequately set forth. Very sensible directions are also given for the detail management of face eruptions, parasites, sebaceous cysts, dental abscesses, hare lip, salivary fistula, excess of hair, etc., as well as affections of the eye. The latter half of the volume (pp. 117 to 185), treats of injuries as well as deformities of the foot, of corns and chilblains, onychia, ulcers, and all the deformities to which ill fitting boots give origin. The congenital and paralytic deformities are also fully considered. The large number of colored lithographs and wood cuts which adorn the book add greatly to its value.

voke diplomas went only to those who had certificates after examination Williams had a diploma, and the Board had no right to revoke his certificate The legislature could not have intended to invest the Board with an absolute power over the reputations and fortunes of graduates of medicine, as no notice or right of appeal was provided for It never intended that the Board should, by a fiat, say who should and who should not practice, and strip them of the value of years of study The case was therefore remanded

THE PENNSYLVANIA REGISTRATION LAW,

Section IV of the Pennsylvania registration law of 1881, requires that diplomas outside of the State must receive the endorsement of a recognized Medical Faculty within the State before registration, but before giving such, the Faculty must be satisfied as to the qualifications of the applicant, and as the endorsement of a diploma is an acknowledgement of the qualifications of its holder as well as of its genuineness, the Faculty of the Medico Chirurgical College of Philadelphia desires to announce that it will endorse no diploma for registration until the holder thereof passes a satisfactory Medical examination The fee for such examination is $30

DOMESTIC CORRESPONDENCE

LETTER FROM NEW YORK

(FROM OUR OWN CORRESPONDENT)

The Late Dr Elsberg—Fractures of the Upper Extremity—New Splint for Fractures of the Lower End of the Humerus—Action of the Academy in the Case of Dr Purdy—The Willard Parker Hospital—General Shaler—Children Bitten by a Mad Dog—Cremation—Dangers of Large Cemeteries

At a meeting of the Academy of Medicine held December 3, Dr Morris H Henry read a review of the life of the late Dr Louis Elsberg and of the advancement of our knowledge of diseases of the throat during his professional career

Dr Samuel W Smith read a paper entitled "Original Deductions based on the Study of One Hundred Cases of Fracture of the Upper Extremities, excluding the Hand" During the reading of the paper Dr Smith exhibited a new apparatus for the treatment of fracture of the clavicle, in which the elbow, secured in a leather string, is drawn inwards and backwards by means of straps passing to a padded band which is placed in the axilla on the opposite side and fastened above the shoulder

Dr Smith also presented a new splint for fractures of the lower end of the humerus involving the joint, which he claimed was the only one that would ensure satisfactory results A varied experience, full of disappointments, in the use of the known splints for the more severe fractures of the condyles, he said, had set him to work to make one with the following requisites (1) To hold the fragments firmly in apposition (2) To allow the forearm to be flexed and extended, pronated and supinated (3) To lengthen or lessen the external angle of the arm with fixation (4) To leave the entire elbow joint exposed for the purpose of making local applications during the whole time of wearing the splint, without disturbing the latter Such an apparatus he had accordingly devised, and it consists of two rods of untempered steel, with ball and socket joint, and fixation screws at the elbow and wrist, the rods being secured to the arm and forearm by means of plaster-of-Paris bandages

At this meeting Dr Agnew presented a resolution, which was unanimously adopted, to the effect that, in the opinion of the Academy, any judicial action which tends to prevent the early reporting to the Board of Health, on the part of the medical profession, of cases of contagious disease, is contrary to public policy and detrimental to the public health This had special reference to the recent case of Brown vs Purdy, in which the Drs Purdy were fined $500 because a patient of theirs was sent to the small pox hospital by the sanitary authorities to whom they had reported the case, the plaintiff claiming that she did not have varioloid, as asserted by the physicians, and asking for $10,000 damages Unless medical practitioners can have some guarantee that they are not liable to such prosecutions as this, the number of contagious diseases reported in this city is likely to be uncommonly small for some time to come

BOOK REVIEWS

Face and Foot Deformities By Frederick Churchill, C M, Surgeon to the Victoria Hospital for Children With Illustrations of New Appliances for the cure of Birth-mark, Club foot, etc 8vo, pp xvi, 195 Philadelphia P Blakiston Son & Co, 1885 Chicago W T Keener

The reason for combining so diverse topics as are indicated in the title of this book will be found in the author's own words in the preface, as follows "It may be asked why I should associate the face with the foot, as these are the two extreme parts of the body? Chiefly because deformities of these members of the body, being more manifest than deformities elsewhere, they constitute a greater hindrance to success in life They not only deform, but deface, by reason of their great disfigurement, the artistic proportions of those parts of the body upon which the eye of the observer most loves to rest "

This short excerpt explains, so far as need be, the meaning of the alliterative title, "Face and Foot," and serves at the same time as a fair example of the writer's very defective and unpleasing literary style But while his sentences are far less skilfully framed than those which lend a charm to the writings of Jonathan Hutchinson and others of our best medical writers, he nevertheless has much of value to tell in this book about nævus and club foot, the two affections with which it is chiefly concerned It is to be noted that the comparatively new and highly successful practice of treating nævi by the needle cautery and perforated metallic plates, is here for the first time adequately set forth Very sensible directions are also given for the detail management of face eruptions, parasites, sebaceous cysts, dental abscesses, hare lip, salivary fistula, excess of hair, etc, as well as affections of the eye The latter half of the volume (pp 117 to 185), treats of injuries as well as deformities of the foot, of corns and chilblains, onychia, ulcers, and all the deformities to which ill-fitting boots give origin The congenital and paralytic deformities are also fully considered The large number of colored lithographs and wood-cuts which adorn the book add greatly to its value

THE USE OF THE MICROSCOPE IN CLINICAL AND PATHOLOGICAL EXAMINATIONS By CARL FRIEDLANDER, Privat-Docent in Pathological Anatomy at Berlin Translated by Henry C Coe, Pathologist Woman's Hospital, New York New York D Appleton & Co , 1885 8vo, 205 pages Jansen, McClurg & Co , Chicago

This is one of the best books of the kind Its descriptions are short, detailed and accurate It does not pretend to cover the field of pathology, but tells how to use the microscope and its various accessories, such as mounting materials and staining reagents, for clinical examination particularly

The chapters upon microscopic accessories and reagents are good, for they give details which are of importance to students, and especially beginners, and are often omitted from other text books At the same time descriptions of complicated accessories which are often described in such works are omitted here, and with advantage, for they are usually useless to those who devote themselves wholly to clinical and ordinary pathological work

A short chapter is devoted to the "Observation of Living Tissues," and one still shorter to an "Examination of the Solid Elements of the Body" "The Examination of Fluids" is treated of at length, and well At first the methods of preparing fluids for examination were given, then in succession and in detail the subjects of blood, sputa, pus, urine, secretions of the genital tract, contents of stomach and intestines, and exudations

It is devoted wholly to descriptions of the methods best adapted to use for making microscopical examinations for clinical purposes By those interested in this subject, and especially by the beginner, will this little book be found valuable The fact that a second edition of it was demanded in Germany in a comparatively short time, is evidence of its worth

THE PHYSICIAN'S VISITING LIST (Lindsay & Blakiston's) FOR 1886 Thirty-fifth year Newly Revised Philadelphia P Blakiston, Son & Co , 1885 Chicago W T Keener

This Visiting-List has stood the test of almost half a century, and its recent improvements should make it still more popular than it has been The dose tables have been rewritten in accordance with the Sixth revision of the U S Pharmacopœia, and contain both the metric and old nomenclature In addition to the Visiting list proper there are pages for memoranda, for addresses, for bills and accounts, memoranda of wants, obstetric engagements, vaccination engagements, obstetric cases, record of deaths, and general memoranda It is compact, convenient, simple and tasteful

INTERNATIONAL CONGRESS

THE COLUMBIA COUNTY MEDICAL SOCIETY ON THE CONGRESS QUESTION

At the regular meeting of the Columbia County Medical Society, State of Pennsylvania, the following resolutions were unanimously passed

WHEREAS, There being a division of sentiment in the medical profession relative to the action taken by the American Medical Association at its meeting in New Orleans, and also as regards the action of the Committee of Arrangements in carrying out its instructions relative to the proposed meeting of the International Medical Congress, to meet in Washington, D C , in 1887,

Resolved, That we reaffirm our allegiance to the Code of Ethics of the American Medical Association, and we hereby give expression to our unqualified endorsement of its action in adding to the Original Committee

Resolved, That this Society approves of the action of the Committee at its meeting in Chicago in deciding to appoint to official positions in said Congress only those who are responsible to the American Medical Association

Resolved, That a copy of this action be forwarded to the Secretary General of the Congress

W M REBER,
Secretary Columbus County Medical Society

THE CLIMATIC TREATMENT OF DISEASE, WESTERN NORTH CAROLINA AS A HEALTH RESORT[1]

BY HENRY O MARCY, A M , M D ,
OF BOSTON

Modern science invests old topics with new interest The fundamental factors of sanitation are now so well understood that the question of climate and its influence upon health and disease may be discussed with the assurance of dealing somewhat, at least, with objective factors, instead of theory and the results of experience alone Every student of modern medicine finds a new inspiration from the great progress already made by the indefatigable labors of a considerable number of trained workers in all the leading countries The one object of research has been to ascertain the causes of communicable diseases

Few will now be found to question the real profit arising from this most difficult problem of scientific research, and that, at least, a clew has been obtained leading to a knowledge of one of the most profound of nature's mysterious workings There are many who accept it as the prophecy of a revelation to come, which shall elevate medicine from the domain of art and place it within the realm of the more exact sciences , a knowledge of fundamental factors upon which to erect anew the Temple of Æsculapius If a contagium vivum plays the rôle in the entire group of zymotic diseases, the study of organic decomposition is not alone a question of chemical interest, but irresistibly leads to conclusions of a biological character, and the scientist finds himself absorbed in watching life processes ,—a struggle for the survival of organisms with their environment, a conflict ending often in the destruction of the higher complex forms of animal life by a foe, so insignificant, so utterly beyond ordinary comprehension, that it seems verily a battle with the powers and principalities of the air

The so called "germ theory of disease" has passed from the realm of theory into that of demonstration as fact, and based upon our present knowledge confessedly fragmentary and imperfect, yet sufficiently exact from which to make deductions, sanitation has become in a large measure a science From this standpoint, climatology is invested with a new interest and value, as seen especially in the contributions of the last few years A surgically clean wound means an aseptic wound The aphorism of Hippocrates, "pure air, pure water, pure soil," signifies now an air, water and soil free from infectious elements of disease, and this must be defined as the most important factor pertaining to a health resort, sought under the name of climate This subject, which is far too large for the present occasion, must be epitomized in a general way as the individual wisely adapted to his surroundings

Life carries with it, as an inherent property, a vital, resisting power by which the individual is able to adapt himself to surroundings and overcome deleterious influences These phenomena we call the "laws of life," beyond the limits of which life itself ceases Thus heat, water, food, oxygen, etc , must be furnished within fixed limits Departures from the ideal standard which we call health lessen the vital, resisting power of organs, as well as of individuals, and pave the way for the introduction of pathological factors Nature has provided man with an armor efficient to withstand and repel the invisible foes with which he is ordinarily surrounded An unbroken skin is a coat of mail invulnerable to his surgical foes The steady police surveillance of the cilia of the epithelium which lines our respiratory passages is ever ready to seize and expel the intruder, be it bacillary, or any other form of atmospheric contamination When the defenders of the castle are disabled, then it especially behooves us to take into watchful consideration the strength and character of ourselves, as well as of our enemies

The chemical and mechanical laws of life have, hitherto, almost entirely engaged the attention of investigators in the study of the circumfusa of the invalid For a number of years committees from the American and British Medical Associations have been engaged in securing data for the comparison of the invasion of acute diseases with meteorological changes Although these latter are largely x factors in the problem, they have a much wider significance than usually supposed, since they make possible conditions not only devitalizing to the individual, but favoring in many instances the growth and development of infectious germs The tides and changes of the great atmospheric ocean, in which we are submerged, are of the utmost significance Its weight, as measured by the barometer, indicates the pressure which our bodies sustain The moisture in suspension not only increases the weight, but modifies its influence upon the individual, and this is measured by the hygrometer The changes of atmospheric temperature, as recorded by the thermometer, are of well recognized importance The atmosphere also varies in its composition, of which, from our present standpoint of consideration, oxygen and ozone may be accepted as the most significant, since these agents materially lessen the growth and development of all the microscopic forms of plant life From the observations of a number of our most competent physiologists, it is probable that the amount of oxygen absorbed in health does not greatly vary whether the individual is at the sea level, or at high altitudes If this is correct, the accepted belief of increased oxygenation of the blood from breathing an air rich in oxygen, as at the sea level, is not true

---

[1] Read before the American Academy of Medicine New York October 29 1885

The effect upon the individual of an ozonized atmosphere is generally conceded to be beneficial, yet, unfortunately, less is known upon this subject than is desired, its antiseptic properties are well recognized, and its influence upon the purity of the atmosphere, if not upon the individual, is undoubted Ozone owes its great influence to its powerful oxidizing qualities The compounds of ammonia, phosphorus and sulphur are acted upon with great rapidity, and the odors resulting from animal decomposition are removed almost instantly It is probably destructive to all the minute vegetable organisms, when in active development, but its effect in destroying the vitality of their spores has not yet been ascertained This has its direct bearing upon the question of climate, since it has been pretty well determined that all the varieties of pathogenic microbes not only do not thrive, but fail to live, except within a narrow range of conditions Pasteur has based his problem of protection from disease by the inoculation of attenuated virus of repeated cultures, upon the belief that these morbific bacteria have lost their specific effects in the presence of free oxygen—that is, these growths are anærobic The experiments of Ogston and Cheyne do not, however, confirm this supposition In a series of cultures of the vaccine coccus, conducted with great care, the cocci bred true and cultivated readily, but the vaccinations which I made from the cultures were entirely without effect A few degrees in temperature will often be sufficient to retard or destroy the development of the bacterial reproduction

Based upon the belief that an aseptic atmosphere is of the first importance in the selection of a climate for the benefit of sufferers from a certain class of diseases, examinations of the atmosphere have been carefully made to demonstrate its purity Miguel and Freudenreich found that microphytes were rare at 800 metres, and absolutely wanting at 2,000 metres above the sea level For physical reasons, high altitudes have been believed to be beneficial in early phthisis, and, influenced by the later demonstrations of a bacillary cause, this aseptic state of the atmosphere is theoretically accepted as promising good results, and sanitary stations for mountain air treatment of consumptives have been established at several selected points in the Alps, where the comforts of home life are furnished to invalids Of these health resorts, Davos and St Moritz are the most popular St Moritz is 6,000 feet and Davos is over 5,000 feet above the sea level, and the latter has become noted for winter treatment, although the average temperature from November to March is only 23° F The number of visitors at Davos last winter was over 1,000, and careful provision is made for home comfort The patients are urged to be active out of doors within the limit of fatigue Each year adds to the number of invalids resorting to these mountain sanitaria, and the statistics show good results It should, however, be borne in mind that the cases sent to these resorts are those selected in the incipient stages of disease, and this is to be taken into the account in the deductions that the recoveries average one fourth , also the time elapsing after the treatment has been too short to determine with accuracy the results This pertains in criticism to the statistics of other similar localities, but it is by no means an easy task to secure satisfactory data, and such a problem can never be subjected to a mathematical analysis

A recent medical visitor writes as follows ' I saw the well known "apostle" of Davos, Dr Spengler, and his son in-law, Dr Peters, whose cordial reception I will not fail to mention here They gave me much valuable information about Davos and its value as a health resort They seem to aim chiefly at strengthening the general system, and the heart in particular I do not think they make systematic use of the milk-cure or of the douche, but the methodical walks up hill form part of the curative system Consumptive patients are benefited by their stay here if the heart be in good functional order, and if they have still a certain amount of strength Erethic, or very weak patients, sometimes lose their sleep as soon as they are here, and, unless they regain it after the first few days of acclimatization, they do better to leave the place altogether Davos seems to be favorable also in the case of torpid, scrofulous patients who want a bracing and exciting atmosphere, for non-irritable anæmics, debilitated and convalescent subjects The fear of tuberculous infection in these large sanitaria may keep away a number of such patients until special hotels have been opened for non-tuberculous persons I spoke with our professional brethren on the occurrence of hæmoptysis, and was told that it was by no means more frequent here than in the plain In a pamphlet, 'Die Landschaft Davos,' I find the following instructive data given by Dr Spengler himself 'Out of 323 patients, 178 never had hæmoptysis, either at home or here (in Davos), 126 had hæmoptysis at home, and none here, sixteen had it both there and here, three first had it here' These figures speak very plainly for themselves "

In America we are indebted to the indefatigable labors of Dr Charles Denison, of Colorado, far more than to any other person, for his masterly study of the Rocky Mountain regions as health resorts

Granting that consumption is dependent upon the development of a bacillus within the lung, what may we legitimately expect from climate for its destruction or expulsion? Its propagation, so far as we now know, is dependent upon a proper soil, which means the furnishing of suitable nutriment in the form of albuminoids, a continuous temperature, and a proper amount of moisture. These supplied, the bacilli reproduce abundantly externally to the individual, and that they do not in any manner lose their pathogenic qualities is shown by their ready reproduction and development, following inoculation, causing the death of healthy animals.

Do climatic changes modify these factors? Much has been claimed for, and written upon the advantages of a dry climate in consumption. There are other reasons why this may give benefit, but I suppose no one will contend that the fluids in the tissues of the lungs are materially lessened thereby, or that, while life continues, these can by any manner of means be so diminished as to prevent bacillary development. The heat point for the bacillary growth must be maintained so long as the individual exists, for its reduction to a point to interfere with its development must be incompatible with the conditions possible for the maintenance of the life of the individual. Given, the depreciation of the vitality of the tissues locally, and that the albuminoids requisite to furnish food for the unwelcome tenants continue, and we safely infer, from what we now know, that an aseptic atmosphere, however, dry or rarefied, cannot alone furnish the factors of cure.

The rôle of bacterial reproduction varies greatly in certain diseases. Thus, in scarlet fever, measles, small-pox, once having run its course, the bacterial development is at an end, and only in the most exceptional conditions can be reproduced in the same individual. In a measure this is true of typhoid, typhus, and yellow fever, and also of diphtheria and perhaps other diseases. Remittent or malarial fever is an exception, and yet after a time the individual either takes on an increased resisting power to the disease, or the conditions necessary for its development are changed and so called acclimitization follows. However, the residents of a malarious country never entirely escape its influence. That it is a new infection, rather than the development of the original seed, appears probable, since ordinarily a residence in a country free from malaria soon causes the disease to disappear. While thus much may be determined from experience, and the sufferers from this disease promised exemption by change of climate, sufficient is not yet known of the rôle of the bacillus malariæ from which to deduce more than the most general conclusions. Enough is known of the bacillus tuberculosis to show that it is found in all countries, making its greatest inroads in thickly settled communities and is most prevalent in cold, damp localities. This latter state may be considered favorable since, thereby, catarrhal conditions of the respiratory passages are induced, and thus a soil favorable for its development is produced. For similar reasons the general vitality, or resisting power of the individual is reduced. That the person thus subject to catarrhal inflammations should be greatly benefited by breathing an aseptic air is easily conceived, since such an individual residing in a city can scarcely escape the breathing of an infectious atmosphere.

Every pathologist knows that a considerably greater percentage of cures in consumption is effected than is generally believed. It is not rare to find localized, cicatricial and calcareous degeneration in the apices of lungs, otherwise healthy, which may be traced to disease incurred even in early life. If caused by bacilli, why did these cases recover? The answer must be, that the conditions for the proper development of the microbe did not pertain, that in some way the vital, resisting power of the tissues was superior to the invasion of the disease, that cells were proliferated, as a protective wall, so to speak, against the invasion of the microbe, which did not furnish the albuminous food necessary for its development. Thus shut in, the disease is necessarily limited and bacterial growth ceases.

Sée, in his recent treatise on "the Bacillary Phthisis," discusses at considerable length, the question of microphytic life, especially that of the bacillus tuberculosis in high altitudes, and considers such a climate of prophylactic character. Recent very interesting experiments, conducted in the pure air of the Adirondack region, show that the development of the bacillus tuberculosis following inoculation and infection of animals does not in any wise differ from the laboratory experiments carried on in the large cities.

Dr. Harold Williams, of Boston, in a carefully prepared paper read before the Massachusetts Medical Society during the present year, reviews certain phases of the question of the adaptability of climate to individuals, and in summing up says: "It seems to me that we must admit, in the present state of our knowledge, the meteorological differences of climate have been proved to be of little importance in the treatment of phthisis, and, furthermore, that clinical evidence would support this conclusion, for the burden of proof lies with those advocates who plead in favor of special climates, and such proof it seems to me is yet to be forthcoming."

This is more than I am willing to admit, since we should look for aid to the infected individual from climatic change, not in the breathing of an "anti-bacillary atmosphere," but in the placing of the patient in surroundings suitable, if possible, to strengthen his weakened, vital, resisting powers, and reinforce his tissue development, so that it may be superior to the attack of the would-be destroyer, and although we do not know all the conditions requisite for counteracting the growth of morbiferous bacilli, we are assured that healthy tissues and blood imperfectly furnish the required pabulum. Were it only necessary to breath an anti bacillary atmosphere, science could solve the problem and give to the sick chamber an antiseptic air fatal to bacterial growth. Many have builded hopes upon such remedial agents and, perhaps, in certain measure correctly, but, given a "pneumatic cabinet" and antiseptic inhalations, we should not expect to affect a diseased gland, a caseous nodule, and only in a certain limited degree, a cavity even, since the air inspired goes almost wholly into the less diseased and healthy portions.

When our present knowledge of infectious diseases is thus reviewed, are we to ignore, as some recent writers have done, the entire question of benefit to be obtained from climatic change? On the contrary, it appears, therefrom, that we have sufficient data by which to add, emphasize and encourage climatic investigations and confirm previous experience, even if the theories, under which it was sought, do not prove true. Equability and dryness of the air are certainly important, well recognised factors in the alleviation of the respiratory tract, and this alone is sufficient to make these conditions of value, in the selection of a residence for such invalids. Atmospheric moisture, in cloud or vapor, is detrimental by lessening the sunlight, and the clear skies of any land are justly prized. This is sometimes called the diathermacy of the atmosphere, and this is increased by the rarefaction of the air. Nearly every one has observed the intensified effect of the sun's rays at high altitudes.

Clinical observations teach that on the invalid able to endure it, active out-of-doors exercise, in elevated localities, has an especial invigorating effect upon the respiratory function and apparatus, the circulation is improved, thereby increasing the oxydation of the tissues, as well as producing a better cellular nutrition and elimination of the effete material. The lowering of the atmospheric pressure also tends to diminish the circulation of the deeper tissues, which in certain conditions of the organs is of great importance—as for example, in renal, hepatic, or cerebral congestions—while, on the other hand, the blood flow to the surfaces is greatly augmented, an important factor in conditions of defective, or perverted cutaneous nutrition. The effect of this is shown in increased appetite and improved digestion, until the imperfectly prepared food, too often forced by necessity, to supply the demand, is taken with a relish never known at home, and digested without knowledge of organs or processes.

With a labor only known to those who have worked in such direction, Dr. Denison has utilized the mass of statistics gathered by the Signal Service Department, and placed before the profession his seasonal maps of the United States. These are worthy the careful study of every physician, and teach many facts of the greatest importance. Under date of June, 1885, he writes in regard to Colorado: "In my practice of twelve years in Colorado, it has been very seldom that I have known of the origination of phthisis here, and with the carefully kept records of nearly twelve hundred cases of asthma, phthisis, chronic pneumonia, etc., I do not remember to have written a certificate of death for one uncomplicated case of phthisis originating in Colorado. Of course there are such cases; I have one under my care at the present time. As civilization progresses here, it will not be strange if the disease becomes much more frequently met with in thickly settled districts, made up as they are of a considerable scattering of regenerated invalids." The weight of evidence is so decidedly in favor of elevation as an important factor in the climate for the consumptive, that it will not answer for any one who has not personally investigated the Rocky Mountain regions, or similar elevated resorts, to say that nothing has been proved for elevation. Everything has been proved, since all the most desirable attributes, dryness, coolness, sunshine, stimulation of increased atmospheric electricity, sandy soil, perfect drainage, and last, but not least, *purity of atmosphere*, are found and increased with elevation above the sea level."

Dr. H. Weber, in his excellent *résumé* of the subject of climatic treatment of phthisis given in the the Croonian lectures, published in the *British Medical Journal* during the present year, emphasizes the advantage gained by the invalid not only from elevation, but also by the cold, dry air, and makes the distinction that in the sunshine the coldness pertains rather to the atmosphere than to the individual. Speaking of his personal experience in the high Alps in November, at the elevation of 10,000 feet, without an overcoat, he says: "As long as I remained in the sunshine I never felt warmer in August or September in the same localities; but in the shade an overcoat would have been just a comfort, though I did not feel cold, in spite of a temperature of only 20° to 25° F., the air being perfectly calm. A black bulb thermometer *in vacuo*, showed in the sun between 88° and 92° F., while an ordinary thermometer registered only between 31° and 32° F." He sums up the advantages attained in mountain health resorts to be as follows: "1st. The atmospheric purity or aseptic nature, the comparative absence of floating matter. 2d. Dryness of the air and soil, comparative absence of mist. 3d. The coolness of the air temperature and the great warmth of the sun-temperature. 4th. The rarefaction and low pressure of the air. 5th. The intensity of the light. 6th. The stillness of the air in winter. 7th. A large amount of ozone. The effects on the invalid suited to such climates are, increase of appetite, improvement of sanguification and general nutrition, strengthening of the heart and circulation, raising of muscular and nervous energy and of activity of the skin."

Observations have been made in some of the South American high altitude stations, as at Janja, of more than 10,000 feet above the sea. The range of temperature during an entire year was between 50° and 60° F., with the sky always clear and sunny, and an atmosphere pure and bracing, which invites to out of doors exercise and enjoyment. In an atmosphere as cold as the winter in the Alps or the Rocky mountains, it is essential to select localities where protection from wind is attained, since the motion of an atmosphere thus cold abstracts heat rapidly. In broad stretches of equable cold, the winds are reduced to a minimum and the absence of moisture greatly increases the hours of sunshine.

The chief objection to the Rocky Mountain health resorts lies in the distance from the centres of population. The White Mountain region affords a very considerable elevation, but, judged in the light of the above experience, too little to secure much good from the rarefaction of the air, since Bethlehem is the higher location of the villages, and this is only 1,800 feet above the sea level.

The Adirondacks are of less elevation, but possess the advantage over the White Mountains in being sparsely inhabited, an almost unbroken forest, an elevated plateau furnishing an equable, cool summer and a decidedly cold winter climate. Through the influence of Dr. Loomis, of New York, a sanitarium has been established for patients to remain the entire year, and good results have been attained, but it is difficult of access, and offers very little advantage from rarefaction of the atmosphere.

The mountains of the Alleghany range have been known to some extent as affording interesting and health giving resorts for summer recreation, and in the southern ranges furnishing summer homes for the residents of Southern States. The entire range is free of malaria, and Ashville, in Western North Carolina, has grown to a village of about five thousand inhabitants, chiefly as a summer resort. The Alleghanies divide, in the northern part of North Carolina, into the Blue Ridge and the Smokies, the latter the boundary line between that State and Tennessee. The triangle thus formed, with South Carolina and Georgia on the south, is filled with cross ranges of mountains and comprises a territory of about fifty thousand square miles. The entire section is elevated in the bed of the streams, or valleys, to about two thousand feet above the sea, and presents a most irregular surface, a sea of mountain peaks, ranging from three thousand to six thousand feet in height. Within an area of fifty miles there are twenty peaks over six thousand feet high, nine tenths of the entire district is an unbroken, primeval forest of the largest growth, chiefly of deciduous trees. It is the oldest geological formation on the continent, of granitic character, and gives the most unmistakable evidence of the corroding tooth of time. Not a lake or a swamp is to be found in the entire region, a fact perhaps without a parallel for an area of equal extent in the world. Feldspar is the predominating factor in the granite, and, owing to its easy decomposition, the rocks have worn more rapidly, giving an excellent soil for tree growth and the purest of water, as seen in an endless series of pearly, musical rivulets.

With a sparse population, such soil and water, there cannot be otherwise than a pure atmosphere. Owing to the difficulties of making railroads in such a mountainous country, until quite recently, the larger portion of this region has been more inaccessible than Colorado, and no part of the United States, east of the Mississippi, equally large, is probably to-day so little known, or possessed of equal natural advantages, so entirely undeveloped.

The possible advantages of a winter residence in this section has, until recently, been untried. Within the last two or three years I have sent a considerable number of invalids to Ashville and other localities, for the most part with excellent results. Owing to my own favorable impressions, I personally surveyed this triangle during the past summer, making several hundred miles on horseback and in carriage. I am indebted to a large number of resident physicians, whose uniform courtesy I am glad to acknowledge, for many of the facts upon which my deductions are based.

Ashville was the central point of observation. Its popularity is likely to prove its ruin as a health resort, too large for a country village, with its purity of surroundings, too small to secure the advantages from sewerage and an uncontaminated water-supply. Its large hotels are badly located in the centre of the business portion of the town, and its beauty of situation is its chief recommendation. Twenty-three hundred feet above the sea, it is splendidly situated on rising ground, with a distant amphitheatre of mountains. As a winter resort it possesses the advantages derived from its southern location, giving a mild climate, not unlike the South of France. From observations now made for a number of years, the mean average of temperature at Ashville is Spring, 52.3°, summer, 71.3°, autumn, 55.3°, winter, 37.2°, year, 55.3°.

Average rain-fall, 40.02 inches, during a period of eight years the thermometer but twice rose above 88°, and only three times fell below 3°. Ashville has offered, hitherto, the essential advantage of being of greater altitude than any other Southern health resort of easy reach by rail, with a dry, pure, and invigorating air, in winter a remarkable freedom from rain and cloud, with warm sunshine, in summer never oppressive heat, and cool nights. Rain makes of the clayey loam a tenaceous mud, which often seriously interferes with out-of doors exercise.

Dr. H. P. Gatchel, of Ashville, who has for years made a careful study of the climate, writes. "The climate of Ashville is no Eden climate. It partakes more or less of the variableness that pertains to the most of our territory. It has some severe winter days and some blustering March weather, but it is on the whole the best climate we have. If it lacks the uniform mildness of a portion of California, it does not, on the other hand, beget that excessive sensitiveness which is engendered in California. It develops a more robust constitution. It seems to afford a favorable medium between the enervating influence of the warm or uniformly mild regions and the overpowering cold of high Northern latitudes. The snow seldom remains many days at a time, even on the high mountains, and its stay in the valleys can generally be measured by hours. The climate of Western North Carolina would be still more desirable if the rain of winter were less than it is. But though this is considerable as compared with the dry interior beyond the ninety-fifth meridian, yet compared with Cincinnati, Louisville, Nashville, and Knoxville, it is moderate. Indeed, the universal testimony of all competent observers establishes the existence of a dry, invigorating atmosphere, the neighboring mountains serving to intercept much of the moisture, and to cause its deposition on the summits and outer slopes. The average rainfall in inches of the different seasons for a period of eleven years is shown to be as follows.

Spring	10.1 inches.
Summer	13.5 "
Autumn	7.1 "
Winter	9.5 "
Total	40.2 inches."

Below, on the French Broad River, are the Warm Springs, noted even by the Indians for their curative powers. Westward, at an elevation of twenty seven hundred feet, is Waynesville, an enterprising town, but here the valley is rather narrow, especially up the Richland Creek, where are located the White Sulphur Springs, justly popular as a summer resort, since the scenery is surpassingly lovely Beyond here the broken ranges extend westward for a hundred miles in picturesque beauty of forest and mountain, but without a single hotel where an invalid can be even comfortable

If tuberculosis is dependent upon the development of a bacillus, then the orthodox belief in the heredity of consumption is subject to revision and modification In evidence upon this question, I quote from a recent letter written by Dr Oliver Hicks, of Rutherfordton, N C

"I have made observations in regard to pulmonary diseases generally, and hereditary tubercular phthisis especially, to which I wish to call your attention, and which I know will influence you in selecting a place of refuge for your phthisical patients My observations and the opinions I have formed are based upon a large practice for twenty years I can show you sons and daughters of ancestors who came to this country and died from tubercular phthisis Many of them are far past the meridian of life, and are in good health, with fair prospects of attaining to ripe old age The grandchildren of these ancestors are in all respects healthy, and are entirely without indication of tubercular or strumous cachexia"

The Tuckaseege and Little Tenneesee rivers water beautiful, wide, elevated valleys, with out-stretching expanse of surrounding forest Their headwaters are in the mountains, which form the dividing chains between South Carolina and Georgia A considerable village, called the Highlands, has been advertised extensively as a health resort It is situated on a broad plateau, covered with oak growth, at an elevation of about four thousand feet, but it is of very difficult access for invalids, being fifty miles from the Western North Carolina railroad and about thirty from rail in South Carolina The roads are never good, and at times well-nigh impassable The rainfall here is excessive, being over seventy inches yearly average for the two years during which observations have been made The changes of temperature are sudden, and during much of the summer, clouds and rain prevail The cooler elevations cause condensation of rain from the moisture ladened winds blowing from over the heated lower lands stretching away to the East and South

Westward is the Nantahala Valley, which is less a valley than a plateau, between the ranges about three thousand feet in elevation Twenty miles by fifty long, it lies in picturesque loveliness, an almost unbroken forest Beneath the great arches of wide stretching birches, maples, and oaks, runs the beautiful river, giving name to the valley, making rippling, laughing music in its merriest mood, flecked with sunshine and shadow, between its banks festooned with thick hedge of kalmia and rhododendron, the wildest, most secluded spot east of the Rocky Mountains The rail will soon reach this valley, and the time will come when the attractions of this locality will draw thousands to enjoy and profit by a sojourn amid these mountains

Farther to the north are the splendid ranges, culminating in the Black, the Roan, the Yellow and Grandfather mountains The growths upon the upper heights are decidedly Alpine in character and afford a greater variety in plant life than any other localities in the United States On top of the Roan, General John B Wilder has erected a hotel, with accommodations for from four to five hundred guests Next year the visitor is promised the ascent by a steam-cable-road in connection with the railroad from Johnston City in East Tennessee The Roan is 6390 feet above the sea and is the highest inhabited spot east of the Rocky Mountains The temperature has been found to be exceedingly equable and the electrical condition of the atmosphere is claimed to offer certain advantages This large hotel has been erected in the belief of great benefit to be derived from a considerable long residence here, based upon the experience of several years during which period a small hotel became very popular

An interesting condensed weekly record is the following from the report of James E Burnett, U S Survey Officer, for the three months ending Oct 15, 1885, station top of Roan Mountain, N C Observations were taken at 6 A M, noon, and 6 P M daily It is to be regretted that the amount of rain fall and clear weather was not recorded

Prof Muttrich, of Berlin, has reached the following conclusion from his forest meteorological researches "That the forest exercises a positive influence on the temperature of the air, that the daily variations of temperature are lessened by the forest, and in summer more than in winter, that the influence of the leafy forest in summer is greater than that of the pine forest, while in winter the tempering influence of the pine forest preponderates over that of the defoliated forest"

So far as I have been able to learn, no studies of a general sanitary character have been made upon this elevated region of the southern Alleghanies

The first writer on the climate of this region was John Rawson, Surveyor General of North Carolina

His history was printed in 1714 and reprinted in 1860 at Raleigh, N C He states "The climate is very healthful, our summer is not so hot as in other places to the eastward in the same latitude Our sky is generally serene and clear, and the air very thin in comparison with many parts of Europe, where consumption and catarrh reign among the inhabitants The winter has several fits of sharp weather, especially when the wind is northwest, which always clears the sky, though never so thick before However, such weather is very agreeable to European bodies, and makes them healthy "

The first scientist who probably visited this region was William Bartram, the botanist, who explored these ranges in the service of the distinguished Dr Fothergill, of London, in 1772, and published the ever interesting report of his travels, in a now rare book, in London in 1778 He never tires of repeating his delight in the beauties of the landscape, the diversity and magnificence of the vegetation, and declares that the Indians, both male and female, are among the finest specimens of physical development he has ever seen of any nationality

F A Michaux, M D also an enthusiastic botanist, gives an interesting account of his travels and collections, which was translated and published in London in 1805 He says "These mountains are getting inhabited very rapidly The salubrity of the air, the goodness of the water, etc , are the causes which attract new settlers hither "

Prof Asa Gray, of Cambridge, reports at considerable length an extensive botanizing tour made in 1841 in the mountains of North Carolina He reviews the labors of the previous explorers, and adds much interesting information of a general, as well as of a special character This is found in the *American Journal of Science* for April, 1842 The late Prof C W Kerr, State Geologist of North Carolina for many years, wrote "By reference to the Sanitary Department of the Census Report of 1870, it will be seen that one of the two or three most healthy localities in the United States is found in the western part of North Carolina, in the Blue Ridge region Indeed, it would be difficult to find a more salubrious climate in the world than the whole mountain section " Of the recent writers, no one has contributed so much of general information and value as Ziegler and Grosscup, in their work entitled "In the Heart of the Alleghanies "

In the Smithsonian Reports for 1856, the late Silas McDowell first called attention to and discussed the thermal or "no frost" zone There are certain considerable localities where frost is unknown, and the seasons, in their vegetation, are quite unlike the adjacent slopes Often in the early spring it is manifest as a green band across the side of a mountain before elsewhere apparent The explanation is the peculiar conformation of the slopes, which modifies the atmospheric currents Sections of this zone are found upon almost every spur of the Blue Ridge south of the Catawba River The season is as long as in South Carolina, while the summer heat is not higher than that of New York No reports from invalids residing in these localities have come to notice, as far as known, but the absence of frost at these elevations adds a very important factor to the rarefaction of the atmosphere, now sought as essential in certain conditions of pulmonary disease of the entire region

The water is pure and abundant, springs bubble up from every mountain-side and clear, crystalline streams run musically through every valley Medicinal waters, sulphur and iron springs, are not rare One great benefit to invalids of all classes lies in the purity of the air, which the extraordinary forest growth does much to render equable in temperature and moisture Dust is unknown The electrical phenomenon of the summer storms is exceptional, a highly ozonized atmosphere results therefrom Notwithstanding the utter disregard of laws of health by the inhabitants, they are a long-lived race of people One intelligent man, past 80, but looking scarcely 60, who delighted in statistics, gave me these, which he had gathered in Macon County With a population of about ten thousand, 136 individuals still living aggregated in age 10,667 years Of the number 26 men, 2,215 years, average 85+ years, 21 women, 1,823 years, average 86+ years, one woman living now in her 107th year

The absence of mosquitoes, gnats and black flies will speak volumes in favor of these mountain forests to those who have sought recreation in the wilds of our border lands in any direction The lack of civilizing comforts is the present drawback, and the invalid who ventures a residence in these remote mountain recesses must provide for himself nearly everything approaching a luxury The lover of nature of either sex will find plenty to occupy and fill the hours with delightful study It is, however, no place for one seriously ill, and the chronic grumbler will never want for occasion to exercise his spleen The absence of good roads and bridges makes locomotion difficult The saddle offers the best of exercise and the surest means of travel, but the railroads approaching from every direction give promise of a new era The mineral wealth, forest growth and productive soil are in evidence of material prosperity to come The pure air, water and climate hold out a hopeful helpfulness to invalids from every land The wise legislator, seeking far reaching results, would do well to consider the advisability of securing, under State control, a large reservation of the higher ranges as a park Its cost, at present, would be merely nominal Like the peaks and glaciers of Switzerland, its indirect returns of monetary gain would be more sure than bonded interest, and its sanitary advantages would be of a value incalculable to millions yet unborn

MEDICAL PROGRESS

OBSTETRICS AND GYNECOLOGY

Leopold's Two Additional Cæsarean Sections, Uterine Suture without Resection of the Muscular Tissue —Altogether, Leopold has performed the Cæsarean five times after the modern method, for which we are indebted to Singer In his first three cases he followed Singer's method exactly (stripping off the serosa, resection of a strip of the muscular tissue on both sides, suture, and dropping of the uterus) In the two cases reported in this paper, he did not resect the muscular tissue, for the reason that he has concluded it is an unnecessary detail Of his five cases, only one died, number four, and she of sepsis, which had set in before the operation Five living children were obtained The conclusions he has reached from these operations are given in this paper as follows 1 The patient to be operated upon is to be examined *per vaginam* as little as possible The external and internal organs of generation are to be carefully disinfected with sublimate (1–2000)or carbolic (three per cent) 2 Operate early—at the end of the first stage of labor 3 Have trusted assistants, thoroughly familiar with the steps of the operation 4 The uterine incision should extend downwards only to the reflection of the peritoneum, and is to be enlarged towards the fundus 5 After removal of the child, and before touching the placenta, draw the uterus out of the abdominal incision, and 6 Control hæmorrhage by compression of the cervix by elastic ligature or bands 7 Resort to stripping of the serous and resection of the muscular coats only when the serous borders do not readily glide over the muscular borders 8 The uterine incision is to be first sutured with silver wire, not including the decidua The inner borders of the muscular walls will come together better if, before drawing on the sutures, the uterus be compressed from side to side When the sutures are drawn together, the borders of the wound readily approximate Do not twist the sutures too tightly The superficial sutures are best of fine silk These superficial sutures should pierce the serous borders twice at the middle of the incision, once toward the end 9 The uterus sutured, the elastic ligature is to be removed, and the abdominal incision treated as after an ordinary laparotomy

The lesson taught Leopold by his fatal case was Where the patient is feverish, the membranes a long while ruptured, a foul discharge from the genitals, then there is probably inflammation extending to the serous covering of the uterus, and disinfection by the vagina or in the abdominal cavity will be, likely enough, of no avail to stop sepsis In such a case, the operation, as outlined above, had better not be undertaken, but, in the present state of our knowledge, the Porro method resorted to —*Archiv fur Gynak*, xxvi, 3—*Amer Journal of Obstetrics*, November, 1885

Strychnine in Post partum Hæmorrhage —Mr Joseph Thompson, in a note on this subject, says Dr Walker calls attention to the influence exerted by strychnine over *post-partum* hæmorrhage, and I can corroborate his observation My father first informed me of its use, and I have been in the habit of giving this remedy (during the last eighteen or twenty years) in all cases where flooding has been expected or has occurred in previous labors, with most satisfactory results I have no notes of cases, but have in my memory several instances where there was a previous history of flooding after labor, but where, when strychnine had been given beforehand, no hæmorrhage came on Strychnine has, no doubt, a marked influence in preventing *post partum* hæmorrhage I usually give five minim doses of the liquor stychniæ in tincture of orange peel three times daily for a month or six weeks before the expected time, and I cannot recall any case of flooding where it had been given in this way —*British Medical Journal*, Dec 5 1885

MEDICINE

Relation of Asthma to Diseases of the Skin —Dr J Duncan Bulkley read a paper on this subject at the recent meeting of the British Medical Association, in which he draws the following conclusions

1 Asthma has been observed in patients with certain diseases of the skin in such a manner as to indicate some occasional relationship between the two

2 Asthma does not occur, probably, in more than 1 per cent of patients with diseases of the skin and those mainly of the class known as exudative or inflammatory disorders

3 This occurrence of asthma in skin patients cannot be looked upon as a coincidence nor is the skin disease to be regarded as a cause of the asthma, but both the skin and bronchial difficulty depend upon the same internal cause, which may be nervous in origin, or may result from some altered condition of the blood

4 While the theory of the dependence of asthma on a state of spasm of the muscular element of the bronchial tubes has very strong evidence in its favor, it is still possible that the paroxysm of asthma may be occasioned by sudden and evanescent swelling of the mucous membrane of the bronchioles, partaking more or less of the characters of the wheals of urticaria, occurring both on the mucous membrane of the mouth and on the skin —*British Medical Journal*, Nov 2, 1885

Sugar in the Blood in Carcinoma —Gabriel Matrai (*Pester Med Chir Pr*, 36, 1885), after an examination of the blood of eleven carcinomatous patients and eleven other persons, states that Freund's theory is incorrect Sugar is found only after the cancerous cachexia has developed, and is due to the cachexia, not to the carcinoma —*St Petersb med Wochenschr*, No 45, 1885

SURGERY

Ligation of the Common Iliac (Artery and Vein) for Pelvic Enchondroma —Professor E von Bergmann *reports the case of a girl, 11 years* old, who had a pediculated enchondroma of the pelvis, arising from the left sacro-iliac articulation, for which he ligated the common iliac artery and vein The operation, which was extra-peritoneal, was completely successful —*Deutsche med Wochenschr*, 42 and 43, 1885 —*St Petersburger med Wochenschr*, No 45, 1885

THE DIAGNOSTIC SIGNIFICANCE OF ANGINA PECTORIS WHEN ASSOCIATED WITH SUDDEN DEATH

Within the last few months the country has been startled by the sudden death of at least six public men Emery A Storrs, the well known lawyer and wit of Chicago, Josh Billings, General McClellan, Mr Hendricks, H B Claflin and Mr Vanderbilt So far as we have been able to learn, an autopsy was not held in the case of any of them Hence the cause of death is not exactly known, although this can be inferred either from the previous history or the mode of death

In the case of Mr Vanderbilt the *exitus lethalis* was extremely sudden and, so far as reported, was not heralded by any prodromata He was stricken down in the midst of apparently vigorous health, while engaged in earnest conversation with a railroad rival In all probability he was under the influence of strong emotion Death was attributed to apoplexy, but, notwithstanding the folly of attempting a diagnosis at this distance and with such meagre facts at command, we are yet led by two considerations to doubt the correctness of that decision These are, the great infrequency of almost instantaneous death from apoplexy, on the one hand, and on the other, the frequency, in men past 60, of rupture, or of sudden arrest of the heart in diastole, in consequence of strong emotion Presumptive evidence, therefore, would indicate that Vanderbilt died of sudden cardiac failure Similarly, the abrupt termination of H B Claflin's life, immediately after the perpetration of a jest, seems to point to a systole of the heart as the cause of death In these two instances there was not, so far as we know, any evidence of preexisting heart disease In the cases, on the contrary, of the first four distinguished men named above, there was a distinct history of angina pectoris or of symptoms allied to it

Although the newspaper accounts of Mr Storrs's last moments did not mention his having suffered pain in the chest, they yet spoke of a distress in the breast for which the attending physician had prescribed, and of which he complained during the night It is not improbable, in view of his subsequent sudden death, that this was either an anginose attack, or that form which Heberden characterized as "*angina sine dolore*" According to the accounts of Josh Billings's last moments, he was sitting in the door of his hotel, chatting cheerfully, when he suddenly complained of agonizing pain in the region of his heart A physician was hastily summoned, but before he arrived the well known humorist had expired General McClellan and Mr Hendricks were both reported to have endured an attack of neuralgia of the heart for hours, and to have expressed thankfulness for the cessation of the agony, although its subsidence, as the next few moments showed, but betokened the inability of the wearied heart to struggle on any longer

In view of these facts is it justifiable to attach diagnostic importance to the occurrence of angina pectoris immediately prior to death? In order to answer this query, the cause of this "suffocative breast pang," must be ascertained if possible Heberden, who, it is well known, gave the name angina pectoris to this pain in the chest, considered it due to a spasm of the heart Contemporaneous and subsequent English authors adopted his view The post-mortem discovery, however, that the hearts of those having died in an attack of angina were in a state of diastole, instead of spastic contraction, proved the incorrectness of Heberden's conclusions Parry was the first to recognize degenerative changes in the coronary arteries of those hearts which had manifested angina, and although his observations were abundantly confirmed, there arose early in this century a strong opposition to the dependence of this symptom upon organic diseases of the heart In consequence of his celebrated case, in which a tumor of the cardiac plexus was discovered *post mortem*, Romberg was led to consider this breast pain as a hyperæsthesia of the cardiac plexus Lancereaux supported this view by two cases in which he found degeneration of the cardiac nerves, together, it should be said, with atheroma of the coronary arteries For a time, therefore, the theory prevailed, at least on the Continent of Europe, that the pain of angina pectoris was of nervous origin and might be quite independent of organic method, for which we are indebted to Sanger. In his first three cases he followed Sanger's method exactly (stripping off the serosa, resection of a strip of the muscular tissue on both sides, suture, and dropping of the uterus). In the two cases reported in this paper, he did not resect the muscular tissue, for the reason that he has concluded it is an unnecessary detail. Of his five cases, only one died, number four, and she of sepsis, which had set in before the operation. Five living children were obtained. The conclusions he has reached from these operations are given in this paper as follows: 1. The patient to be operated upon is to be examined *per vaginam* as little as possible. The external and internal organs of generation are to be carefully disinfected with sublimate (1–2000) or carbolic (three per cent.). 2. Operate early—at the end of the first stage of labor. 3. Have trusted assistants, thoroughly familiar with the steps of the operation. 4. The uterine incision should extend downwards only to the reflection of the peritoneum, and is to be enlarged towards the fundus. 5. After removal of the child, and before touching the placenta, draw the uterus out of the abdominal incision, and 6. Control hæmorrhage by compression of the cervix by elastic ligature or bands. 7. Resort to stripping of the serous and resection of the muscular coats only when the serous borders do not readily glide over the muscular borders. 8. The uterine incision is to be first sutured with silver wire, not including the decidua. The inner borders of the muscular walls will come together better if, before drawing on the sutures, the uterus be compressed from side to side. When the sutures are drawn together, the borders of the wound readily approximate. Do not twist the sutures too tightly. The superficial sutures are best of fine silk. These superficial sutures should pierce the serous borders twice at the middle of the incision, once toward the end. 9. The uterus sutured, the elastic ligature is to be removed, and the abdominal incision treated as after an ordinary laparotomy.

The lesson taught Leopold by his fatal case was: Where the patient is feverish, the membranes a long while ruptured, a foul discharge from the genitals, then there is probably inflammation extending to the serous covering of the uterus, and disinfection by the vagina or in the abdominal cavity will be, likely enough, of no avail to stop sepsis. In such a case, the operation, as outlined above, had better not be undertaken, but, in the present state of our knowledge, the Porro method resorted to.—*Archiv für Gynak.*, xxvi, 3.—*Amer. Journal of Obstetrics*, November, 1885.

Strychnine in Post partum Hæmorrhage.—Mr. Joseph Thompson, in a note on this subject, says: Dr. Walker calls attention to the influence exerted by strychnine over *post-partum* hæmorrhage, and I can corroborate his observation. My father first informed me of its use, and I have been in the habit of giving this remedy (during the last eighteen or twenty years) in all cases where flooding has been expected or has occurred in previous labors, with most satisfactory results. I have no notes of cases, but have in my memory several instances where there was a previous history of flooding after labor, but where, when strychnine had been given beforehand, no hæmorrhage came on. Strychnine has, no doubt, a marked influence in preventing *post partum* hæmorrhage. I usually give five-minim doses of the liquor stychniæ in tincture of orange peel three times daily for a month or six weeks before the expected time, and I cannot recall any case of flooding where it had been given in this way.—*British Medical Journal*, Dec. 5, 1885.

MEDICINE

Relation of Asthma to Diseases of the Skin.—Dr. L. Duncan Bulkley read a paper on this subject at the recent meeting of the British Medical Association, in which he draws the following conclusions:

1. Asthma has been observed in patients with certain diseases of the skin, in such a manner as to indicate some occasional relationship between the two.

2. Asthma does not occur, probably, in more than 1 per cent. of patients with diseases of the skin, and those mainly of the class known as exudative or inflammatory disorders.

3. This occurrence of asthma in skin patients cannot be looked upon as a coincidence, nor is the skin-disease to be regarded as a cause of the asthma, but both the skin and bronchial difficulty depend upon the same internal cause, which may be nervous in origin, or may result from some altered condition of the blood.

4. While the theory of the dependence of asthma on a state of spasm of the muscular element of the bronchial tubes has very strong evidence in its favor, it is still possible that the paroxysm of asthma may be occasioned by sudden and evanescent swelling of the mucous membrane of the bronchioles, partaking more or less of the characters of the wheals of urticaria, occurring both on the mucous membrane of the mouth and on the skin.—*British Medical Journal*, Nov. 2, 1885.

Sugar in the Blood in Carcinoma.—Gabriel Matrai (*Pester Med. Chir. THE DIAGNOSTIC SIGNIFICANCE OF ANGINA PECTORIS WHEN ASSOCIATED WITH SUDDEN DEATH.

Within the last few months the country has been startled by the sudden death of at least six public men: Emery A. Storrs, the well known lawyer and wit of Chicago, Josh Billings, General McClellan, Mr. Hendricks, H. B. Claflin and Mr. Vanderbilt. So far as we have been able to learn, an autopsy was not held in the case of any of them. Hence the cause of death is not exactly known, although this can be inferred either from the previous history or the mode of death.

In the case of Mr. Vanderbilt the *exitus lethalis* was extremely sudden and, so far as reported, was not heralded by any prodromata. He was stricken down in the midst of apparently vigorous health, while engaged in earnest conversation with a railroad rival. In all probability he was under the influence of strong emotion. Death was attributed to apoplexy, but, notwithstanding the folly of attempting a diagnosis at this distance and with such meagre facts at command, we are yet led by two considerations to doubt the correctness of that decision. These are, the great infrequency of almost instantaneous death from apoplexy, on the one hand, and on the other, the frequency, in men past 60, of rupture, or of sudden arrest of the heart in diastole, in consequence of strong emotion. Presumptive evidence, therefore, would indicate that Vanderbilt died of sudden cardiac failure. Similarly, the abrupt termination of H. B. Claflin's life, immediately after the perpetration of a jest, seems to point to a systole of the heart as the cause of death. In these two instances there was not, so far as we know, any evidence of preexisting heart disease. In the cases, on the contrary, of the first four distinguished men named above, there was a distinct history of angina pectoris or of symptoms allied to it.

Although the newspaper accounts of Mr. Storrs's last moments did not mention his having suffered pain in the chest, they yet spoke of a distress in the breast for which the attending physician had prescribed, and of which he complained during the night. It is not improbable, in view of his subsequent sudden death, that this was either an anginose attack, or that form which Heberden characterized as "*angina sine dolore*." According to the accounts of Josh Billings's last moments, he was sitting in the door of his hotel, chatting cheerfully, when he suddenly complained of agonizing pain in the region of his heart. A physician was hastily summoned, but before he arrived the well known humorist had expired. General McClellan and Mr. Hendricks were both reported to have endured an attack of neuralgia of the heart for hours, and to have expressed thankfulness for the cessation of the agony, although its subsidence, as the next few moments showed, but betokened the inability of the wearied heart to struggle on any longer.

In view of these facts is it justifiable to attach diagnostic importance to the occurrence of angina pectoris immediately prior to death? In order to answer this query, the cause of this "suffocative breast pang," must be ascertained if possible. Heberden, who, it is well known, gave the name angina pectoris to this pain in the chest, considered it due to a spasm of the heart. Contemporaneous and subsequent English authors adopted his view. The post-mortem discovery, however, that the hearts of those having died in an attack of angina were in a state of diastole, instead of spastic contraction, proved the incorrectness of Heberden's conclusions. Parry was the first to recognize degenerative changes in the coronary arteries of those hearts which had manifested angina, and although his observations were abundantly confirmed, there arose early in this century a strong opposition to the dependence of this symptom upon organic diseases of the heart. In consequence of his celebrated case, in which a tumor of the cardiac plexus was discovered *post mortem*, Romberg was led to consider this breast-pain as a hyperæsthesia of the cardiac plexus. Lancereaux supported this view by two cases in which he found degeneration of the cardiac nerves, together, it should be said, with atheroma of the coronary arteries. For a time, therefore, the theory prevailed, at least on the Continent of Europe, that the pain of angina pectoris was of nervous origin and might be quite independent of organic changes in the heart walls Indeed, no less an authority than Eulenburg, in his article upon this subject in the fourteenth volume of Ziemssen's "Cyclopædia of Medicine," advocates this view, and, like Landois, would divide angina into several different categories

Nevertheless, there has gradually been manifested a tendency to return to the view that true angina pectoris is dependent upon degenerative changes in the cardiac muscle These again are the result of defective nutrition either in consequence of atheroma of the coronary vessels or of valvular lesions These changes in the muscle may be either acute, with acute circumscribed softening, or chronic, as chronic fibroid degeneration with thinning of the wall affected Leyden, of Berlin, has recently advocated this view, and English writers, Balfour, Bramwell, Fothergill and others coincide with Leyden In consequence of these changes in the walls of the ventricles, chiefly the left, the heart becomes weakened and either ruptures or becomes paralyzed by some sudden increase in internal pressure which would have once been borne without injury If now, these facts be kept in mind, the great significance of angina pectoris in individuals past middle life becomes apparent and a correct ante-mortem diagnosis of the cause of sudden death possible

THE CLINICAL ASPECT OF GLYCOSURIA

Such is the title of an interesting and comprehensive paper read at the late annual meeting of the British Medical Association, by DR PAVY, whose name is sufficient guarantee of the value of the communication His paper, which was the introduction to a discussion on glycosuria, was followed by one on "Acute Febrile Glycosuria," by Dr Markham Skerritt, and a paper on "Glycosuria," by Dr W R Thomas, all of which are to be found in the *British Medical Journal,* of December 5

The first striking feature in Dr Pavy's paper is a table showing the ages in 1,360 cases of diabetes at which the disease set in, which shows that 30 73 per cent , almost one third of the cases, occurred between 50 and 60 years of age, 24 92 between 40 and 50, giving 55 65 per cent between 40 and 60 "From this period there is a sharp and increasing fall in both directions " This table represents the cases from private practice, and Dr Pavy thinks that a table of hospital cases would show that the greater number consists of patients from 15 or 18 up to 35 or 40 years of age Of the cases tabulated 960 were males and females, a disproportion in favor of males that is rather contrary to the experience of some practitioners Eight of the cases occurred under 10 years, thirty-four between 70 and 80, and one over 80 As regards the family history of glycosuria, Dr Pavy says there can be no doubt that the disease runs in families, in support of which he gives some very striking examples This, however, is only in accord with what seems to be the general experience of accurate observers

As is very well known, the appearance of glycosuria may be sudden, or very gradual In this connection Dr Pavy refers to the fact that the disease may exist for some time without exciting suspicion, and be discovered by the white stains left on the black trousers of patients, the stains being due to the drying of the urine which has splashed on the clothing It is especially in old people that the disease comes on insidiously In regard to the sometimes sudden onset, Dr Pavy mentions the case of a lady who suddenly became very thirsty in the course of an evening and was, on examination, at once recognized as suffering from diabetes Is it not probable, however that many of the cases of sudden onset of diabetes are those in which diabetes insipidus has already existed unnoticed? The exact relation of diabetes insipidus to diabetes mellitus is not definitely defined They may exist together, and their coexistence may be proved Or the usual order may be reversed, and diabetes mellitus be followed by diabetes insipidus

As it is to the nervous system that we must look for an explanation of glycosuria, it is all-important that the nervous symptoms arising in the course of the affection should be carefully noted Dr Pavy is satisfied that " certain symptoms of disordered nerve-action, especially spinal are very apt to accompany diabetes " He has seen so many cases of ataxia associated with this disease, that he has for some time past been led to consider that there is some connection between the two They may come on together, or one may precede the other Again, " pains and manifestations of perverted sensibility are noticed, without ataxia " Exophthalmic goitre is sometimes seen in connection with diabetes, but Dr Pavy is not prepared to insist on a relationship between the two, as with diabetes and ataxia He does not believe in the theory involved in the term " acetonæmia," but is " inclined to consider that the coma depends rather on the exhaustion of certain nerve centres than on the action of any direct poison on the blood " As regards the fatty condition of the blood frequently observed in cases of diabetes, and which has been suggested as a possible explanation of the coma, through the production of fatty emboli, he maintains that it is a purely physiological state " Fat exists normally in the blood after the ingestion of a meal containing much fatty matter "

In the discussion, MR LATHAM called attention to the close relation which, he believed, existed between diabetes, gout and rheumatism He thinks that there are two distinct forms of diabetes 1 One dependent upon modified innervation of the liver, the glucose absorbed from the alimentary canal passing unchanged through the portal system into the general circulation, gout being the analogue of this disorder The glycocine from the glycocholic acid of the bile is reabsorbed from the alimentary canal, instead of undergoing normal transformation, gives rise to uric acid, "which, acting on an enfeebled portion of the medulla oblongata, gives rise to gout" 2 Another form of diabetes has its origin in the changes in the muscular system, and has its analogue in rheumatism The constituent of muscular tissue, which, liberated in excess, gives rise to glycocine and uric acid, and sometimes causes rheumatism, has its oxidation partially interfered with, is hydrated into glycollic acid, which is converted into methyl aldehyde when oxidized Hyperpyrexia from rapid oxidation of lactic acid may result, or lactic acid may be oxidized into aldehyde and thence into acetic acid (from which acetone may be produced) if oxidation be interfered with He regards the distinction between the two forms as of importance in regard to treatment In the second class of cases salicylic acid, gr xl–lxx a day, is of great service, the diet being only slightly restricted In the cases of the first class salicylic acid, he says, has no effect The urine from the second class often contains some substance which dissolves cuprous oxide, and interferes with Fehling's test—a very important point

CIRCULAR CONCERNING THE ORGANIZATION OF THE NINTH INTERNATIONAL MEDICAL CONGRESS

The Secretary-General, by order of the Executive Committee, has issued an official circular announcing the Preliminary Organization of the Congress It contains the list of General Officers who will be nominated for election by the Congress, the members of the Executive Committee, the local Committee of Reception at Washington, and the *Rules* adopted by the Committee on Organization, in the three official languages, English, French and German It is being circulated extensively both in Europe and America

This preliminary circular closes with the following paragraphs "A list of the Presidents, Vice-Presidents, Secretaries, and Members of Council for each Section, will be given in the full programme, to be published at a later period in the progress of the work

"The Executive Committee cordially invites members of the medical profession and men eminent in the sciences collateral to medicine, in all countries, to participate in the International Medical Congress of 1887

"Communications and questions relating to the business of the Congress should be addressed to Dr N S Davis, Secretary-General, 65 Randolph street, Chicago, Illinois "

We are informed that the organization of the Sections is already well advanced, and the work of arranging the full programme for the Congress will be prosecuted by the Executive Committee as actively as possible

AMERICAN PUBLIC HEALTH ASSOCIATION

The recent meeting of this important National Organization in Washington was well attended, and many important papers and reports were presented, as our readers will learn from the unusually full report of the proceedings which is being published in our columns The opinion seemed to prevail very generally among those present, that the General Government ought to establish some kind of National Health Organization, but in regard to details as to the form the organization should take, there appeared to be as great a diversity of views as ever Some advocate the reinvigoration of the National Board of Health, some, the establishment of a new Board to be composed of members selected from the several State Boards of Health, others, a Bureau of Health headed by a Commissioner as an attachment to either the Interior, the State or the Treasury Departments of the General Government, while a few at least, advocate a distinct Department of Health on the same basis as the Departments of the Interior, the Treasury, etc , and the official head of which would be a Cabinet Officer The latter would not only constitute the most efficient method, but it would be more in accord with the extent and importance of the interests to be committed to the care of such a department

CLOSE OF VOLUME V

It is hardly necessary to remind our readers that the present number completes the fifth volume of THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, and contains a full index and title-page As the first number in January will commence Vol VI, the present is an excellent time for new subscribers to send their addresses and the five dollars for THE JOURNAL one year A few of our *subscribers* are in arrears, and should send us the amount due without delay

We are informed by the Treasurer that a considerable number of members of the Association have thus far failed to send him their membership dues for the current year All such should forward the amount due to the Treasurer, Richard J Dunglison, M D , Lock Box 1274, Philadelphia, without further delay

CHOLERA AND SMALL-POX — The first of these diseases still prevails to some extent in Spain and in one Province, Palermo, in Italy, while the latter continues to destroy a number of lives in Montreal and its environs each week

SOCIETY PROCEEDINGS

AMERICAN PUBLIC HEALTH ASSOCIATION

Thirteenth Annual Meeting, held at Washington, D C, December 8, 9 and 10, 1885

(Specially reported for THE JOURNAL)

(*Continued from page 694*)

TUESDAY, DECEMBER 8—EVENING SESSION

THE PRESIDENT called the Association to order at eight o'clock, and introduced Dr J M TONER, Chairman of the Reception Committee, who stated that it was expected that the President of the United States would be with them that evening, but a letter, which he asked the Secretary to read, fully explained the President's absence

EXECUTIVE MANSION,
WASHINGTON, DECEMBER 7, 1885

DR J M TONER

My Dear Sir —I am sorry that the condition of the public business is such that I cannot accept the invitation which you kindly tendered me in behalf of the American Public Health Association to attend its annual meeting tomorrow evening I beg to assure you that my expression of regret is not merely formal, but actually indicates a sense of deprivation which attends an inability to give by my presence, as requested, the fullest endorsement of the object and purposes as well as the work of the Association

Surely "the advancement of sanitary science" and its practical application to the public health are of immense importance to the people of our land Of course, the value of efforts in the direction of a better understanding of the causes of disease and protection against the same, is too palpable for suggestion or argument But I do not think the advantages of an improvement in the condition and sanitary surroundings of the homes of our workingmen and of the poor among us is sufficiently appreciated Healthful and comfortable habitations indicate the best feature of a country's prosperity and advancement , and men with good health and wholesome surroundings are apt to be contented and useful citizens The difference in the death rate of cities and localities unexplained by natural and inherent causes, is of itself enough to give great prominence to the work of the Association , and if this beneficent organization shall succeed, as it ought, in impressing upon municipalities the duty of sensible and thorough sewerage , a plentiful and pure supply of water and general cleanliness, together with a proper construction of school buildings for the children of their citizens, it may well point with pride to its achievements With the hope that the Association may be the means of constantly increasing benefits to the country, and with expressions of heartiest sympathy with its work, I am, Yours sincerely,

GROVER CLEVELAND

PRESIDENT CLEVELAND ELECTED AN HONORARY MEMBER

DR TONER then moved that the President of the United States be elected the first honorary member of the Association, which was adopted unanimously

DR TONER then delivered the

ADDRESS OF WELCOME

He said that, however appreciative he was of the importance of the work in which the Association was engaged, he lacked the ability to fully voice the sincere and hearty sentiments of good-will for the medical profession, and all laborers in the sciences which have for their aims the advancement and good of the human race All know the beneficent aims of this Association, and the great value of your recommendations to public health authorities, and look hopefully to the benefits which cities, towns, hamlets and rural homes throughout the land may derive from a thorough and impartial consideration by you, to solve the many complex questions of sanitary science The legislatures of the States and the councils of cities are now willing to be advised by competent sanitarians as to the causes of diseases and the adoption of necessary means for their removal or prevention A knowledge of the laws of health does not come to a man by intuition, but by education and experience He then spoke of the International Sanitary Conference held in Washington in 1882, and the appointment of the several commissions to investigate cholera and yellow fever He then referred to the approaching meeting of the International Medical Congress, to meet in the City of Washington in 1887

DR JAMES E REEVES then delivered

THE PRESIDENT'S ADDRESS

(See page 645, THE JOURNAL of Dec 12)

WEDNESDAY, DECEMBER 9, SECOND DAY

THE PRESIDENT called the Association to order at 9 30 A M The attendance was much larger than the day before, there being 126 who had registered

The following were

ELECTED MEMBERS

Drs G A Doren, Columbus, O , B C Brett, Green Bay, Wis , D I Wallace, Newark, N J , F Edmister, Brooklyn, L Slusser, Canton, O , Robert Martin, Milwaukee, F Montezambert, Quebec, George Cook, Concord, N H , A J Wolff, Hartford, W G Alling and L J Sanford, New Haven, D R Hagan, Chas McMillan, J O Stanton, Wm M Gray and T E Hammond, Washington, D C , W E Taylor, Monmouth, Ill , MM George W Baird, U S Navy, M H Stauffer, Allegheny, Pa

The following were

ELECTED ASSOCIATE MEMBERS

Drs Llewellyn Eliot and E P Bliss, and MM John Frazer, Edward Coverly, and F B Sands, of Washington, D C

The Executive Committee also reported that it had not deemed it expedient to adopt the resolution offered on the previous day, by Dr R Harvey Reed, in the matter of securing legislation for the prevention of the sale of diseased meats

The Secretary reported that the Cosmos Club, of Washington, had extended a cordial invitation to the members of the Association, to call upon them at any time during their stay in Washington

Dr P H Bryce, of Toronto, Canada, read an exhaustive paper on

SMALL-POX IN CANADA, AND THE METHODS OF DEALING WITH IT

After stating that he felt like a lawyer before a criminal court, pleading for a criminal who has boldly declared himself "not guilty" of an epidemic of small-pox, the speaker proceeded to relate the circumstances of the outbreak of the present year, stating that it was not until a prominent politician had died from the disease that the entire outside world and Montreal herself awoke to the situation The number of deaths was about 3,000, or about one to every infected house Unfortunately the epidemic was not confined to Montreal alone Among the French the system of sanitation was unable to grapple with the disease Knowing this, the health authorities of Montreal provided the local boards of health with instructions and did everything in their power to warn them of their danger The speaker described in detail the special regulations which were drawn up by the Ontario authorities and the means taken to prevent the spreading of the epidemic All goods, merchandise and people passing in or out of the province were strictly examined The railways lent ready aid in the cause of inspection, and every car was examined and all the railway officials vaccinated Merchandise certificates were issued and the merchants availed themselves gladly of this system, which prevented the cancelling of a large number of their orders Passengers were asked if they came from Montreal, what street and number, and if it was found that they came from near an infected house, their baggage was taken and fumigated, and themselves quarantined for a time In the Province of Quebec equal precautions were taken to prevent the spreading of the epidemic In conclusion the speaker said he thought it very creditable to Ontario that it had succeeded in establishing an internal quarantine through which no case of disease had passed to the neighboring States He thought that the common sense of justice of the association would lead it to agree with him that the unreasonable continuance of the quarantine at the Suspension Bridge should be removed

Dr Wm H Hingston, of Montreal, said My city has been afflicted as no other city on this side of the Atlantic has ever been afflicted But I must say that no city could have made more tremendous efforts to free itself of its affliction It has been mainly through the aid of the United States authorities that the rules for vaccination were enforced more thoroughly than could otherwise have been possible, and he took the occasion to thank the Union for its assistance Montreal had to create legislation for itself on account of its distance from the seat of government, but these rules were sent by special messenger to Quebec and within forty eight hours they were law No province could have done more to rid itself of its epidemic than had Quebec There were no small-pox hospitals or isolated buildings in which patients could be placed, until the outbreak of the disease Disinfection according to the most modern methods was employed The speaker then described the opposition which the health authorities had met with in their efforts for inspection and disinfection

The deaths from small pox in Montreal, he said in conclusion, numbered, as has been stated, 3,000 But by the death of 3,000 children it must not be supposed that it means 3,000 houses in mourning In some of the States, I believe, there is one child to two or three houses, and in such places this number of deaths would affect about 6,000 homes Now, our birth rate, I am happy to say, is enormous No country in the world can exceed it So if you will divide the 3,000 deaths by 5 or 6, you will probably get the number of houses to day in mourning in Montreal

Dr James M Watson, of New Jersey, moved that hereafter, members engaging in discussion of a paper be restricted to five minutes Adopted

Dr Wm M Swift, Quarantine Officer of New York, spoke in detail of the manner in which inspection of Emigrants is carried on at the port of New York City

Dr A N Bell, of New York, denounced the authorities in Montreal for not having the people vaccinated at the outbreak of small pox in that city, and for delaying this important step so long He considered it a crime for a community to have small-pox The gentleman preceding him spoke of the hardships of quarantining their people, they deserved it This epidemic did not come because Montreal is a filthy city, but on account of the bad system of vaccination in use there

Dr Bushrod W James, of Philadelphia, favored compulsory vaccination for the whole country, quarantining people having small-pox, and putting them into the small-pox hospital

Dr James A Stewart, Commissioner of Health of Baltimore, called attention to the dangers resulting from public funerals of persons dying from epidemic diseases

Dr W K Newell, of Jersey City, thought persons ought to be vaccinated two or three times if necessary, or until the last operation produces no result He had adopted a system of vaccinating twice on each arm Care was necessary as to what vaccine was employed

Dr C W Chancellor, of Maryland, read a paper on

IMPURE AIR AND UNHEALTHY OCCUPATIONS AS PREDISPOSING CAUSES OF PHTHISIS

He stated that in England one-fifth of all the deaths occurring are from pulmonary consumption, in France, one-sixth, and in Germany and Austria about one-seventh In the census year of 1880 one-eighth of the deaths occurring in this country were from consumption The causes which lead to this fearful mortality demand more than ordinary consideration.

It cannot be denied that some occupations are more unhealthy than others. There can be no doubt that the inhabitants of cities are less hardy and more subject to pulmonary disease than those of the country. City people, speaking generally, are pale, of lymphatic temperaments, and their muscular system is but poorly developed. Want of a free circulation of a pure, uncontaminated atmosphere is the most powerful cause of this. In addition to this, in cities the passions are more excitable, indulgence in eating and drinking is more common, with many life is sedentary, and the occupations are altogether more unhealthy than those in the country. Take, for example, those engaged in mercantile life—merchants and clerks. These, for sanitary purposes, may be divided into three classes—first, those who have but little exercise, such as book-keepers, second, those who have exercise but are confined to their stores in a superheated, unhealthy atmosphere, as, for example, salesmen, and third, those who have exercise in the open air, or who do out door work. In the first class the digestive organs suffer, the next from diseases of the pulmonary organs, and the third from the prostrating effects induced by over-mental or bodily exertion or by corroding care.

Salesmen are liable to their diseases because they are constantly exposed to their exciting causes, the principle of which are an impure atmosphere and exposure to sudden changes of temperature.

Referring to artisans and laborers who work in manufactories and shops, many of which are badly located, badly ventilated and often abounding in unhealthy dust, under such circumstances said the speaker, the most substantial nourishment, the most temperate habits, cannot prevent their becoming blanched and weakened by disease. Persons habitually breathing a dust-laden atmosphere, as in some manufactories, are more especially liable to pulmonary complaints.

The problem of how to face this evil is simply, How to environ each worker in the prosecution of his work with a pure atmosphere? The solution of the problem could be easily suggested by the sanitary engineer, but its execution is a matter for the Legislatures of the several States. In the meantime it is extremely desirable and even necessary that consumptive hospitals should be established in every city. London has its half dozen and other European cities are not without some provision, but in this country, even in many of the larger cities there is no provision made for so necessary an object. It would be a great and truly useful work to devote an edifice in every large city to so benevolent a purpose.

DR. I. N. QUIMBY thought that some distinction should be made between consumption acquired by occupation and the hereditary form of the disease. He thought that about 75 per cent was acquired, and about 25 per cent hereditary.

DR. BUSHROD W. JONES, of Philadelphia, spoke of an inflammatory condition that may arise and is caused by the presence of fine particles of dust. This should be regarded as a traumatic cause, irritating the mucous membrane, and a distinction should be made between this and the combined causes as impure air, poor food, badly ventilated rooms, etc.

It was then decided to make the report of the Committee on Disinfectants the special order for Thursday morning.

COMMISSIONS ON WORKSHOPS.

DR. HENRY LOMB, of Rochester, offered a resolution recommending that the Government appoint two commissions of three members each, who should visit different parts of the country and examine workshops, etc., with the view of ascertaining what arrangements are made for the health of the operatives, and to recommend remedial measures.

(*To be continued.*)

DOMESTIC CORRESPONDENCE.

CONJUNCTIVITIS DEPENDENT UPON DISEASE OF THE INTRA-NASAL TISSUES.

TO THE EDITOR OF THE JOURNAL:

Dear Sir:—In connection with the references to the above subject in THE JOURNAL for Nov. 14, p. 538, and Dec. 12, p. 672, permit me to call attention, without comment, to the following passage taken from a paper read by your correspondent April 28, 1883, before the Medico-Chirurgical Faculty of Maryland (*vide* Trans., p. 274). "The inflammation of the conjunctivæ which is so often observed in connection with nasal catarrh is generally explained by the extension of the inflammation process through the nasal duct, but I am inclined to regard it in the majority of instances, as a reflex vaso motor phenomenon, the vessel dilatation being kept up by the constant irritation of the sensitive nasal area. In like manner I would explain the recurrent herpes and keratis which have been observed in connection with this disease, the phenomena in these cases being called forth by trophic disturbances." The subject is also alluded to by Hack, of Freiburg (Ueber eine operative Radical-behandlung bestimmter Formen von Migrane, etc., Wiesbaden, 1884), and is now familiar to most specialists in throat affections.

In regard to the reflex dependence of aural phenomena upon disease of the turbinated nasal structures, your correspondent would also like to direct attention to a few sentences from former publications of his own which antedate the recent discussions of this subject in the medical journals. "There is still another way, however, in which morbid conditions of the nose may react upon the circulation and upon the nutrition of the aural chambers, viz. through the reflex agency of the vaso motor and trophic nerves. I am led to the assumption of reflex irritation by the pain and congestion in the ear which occasionally follow the manipulation of instruments within the nasal cavities, or the application of caustics or other remedies to their lining membrane, and furthermore, by the existence of symptoms referable to the ear (tinnitus, pain, etc.), which cannot be explained on any other hypothesis."—*Trans. Med.-Chir. Faculty, Maryland, 1883*, p. 275.

"My experience is, that long standing occlusion of the nostril from deflected septum is always associated with hypertrophic catarrhal conditions of the turbinated bodies and the mucous covering of the septum behind the deflected portion This becomes the starting point of inflammatory disease of the lower air passages and middle ear Inflammation of the former occurs either as the result of mouth breathing and direct extension, or, as I have pointed out elsewhere (*Am Jour Med Sc* , July, 1883), may be the outcome of the constant hyperæmia induced by reflex nasal irritation, the vessel dilatation being kept up by the prolonged stimulation of the reflex centres from chronic nasal inflammation In the same way, I believe that reflected irritation from the turbinated tissues of the nose may react upon the circulation and nutrition of the aural chambers I have recently called attention (*Trans M C Fac* , *Md* , and *Trans Am Laryngol Assoc* , 1883) to this reflex agency of the vaso motor and trophic nerves in the production of middle ear disease, to the recognition of which I was led by the accidental production of symptoms referable to the ear (such as tinnitus, pain, stoppage, etc) during operation procedures in the nose Although my experiments upon this point have as yet taken no definite form, it is quite possible that the aural affection in these cases may find its explanation in pathological conditions of the reflex sensitive area which I have shown to exist in the nasal mucous membrane (*Am Jour Med Sc* , l c) At least, in several cases I have succeeded in reproducing them by artificial stimulation of this area This is a fact of considerable practical importance in the solution of many obscure and intractable cases of middle ear disease whose etiology has been heretofore unrecognized"—*Trans Va State Med Soc* , p 121

Baltimore, Dec 18, 1885

BOOK REVIEWS

Practical Histology and Pathology By Heneage Gibbs M D , Lecturer on Normal and Morbid Histology in the Medical School of the Westminster Hospital Third Edition 8mo, pp 200 Philadelphia P Blakiston, Son & Co 1885 Chicago W T Keener

The scope of the work can be seen readily from the following headings of chapters "Microscope," "On Preparing Tissues for Examination," "On Section Cutting," "On Staining," "On Double Staining," "On Mounting," "On Injecting the Vascular System," "Method of Obtaining Animal Tissues for Examination," "On Preparing and Mounting Pathological Specimens," "On Bacteria," "On Staining Bacteria" The first chapters deal with microscopical technique and are very good, though we cannot commend them as highly as the little book of Friedlander, which was noticed in these pages a few weeks ago More formulæ for staining fluids are given in this than in the latter work, but the directions for manipulating specimens are not so detailed and explicit The chapter pertaining to pathological tissues is short and least satisfactory The chapter on the staining of bacteria is devoted almost exclusively to the staining of tubercle bacilli

The Science and Art of Midwifery By William Thompson Lusk, A M , M D , Professor of Obstetrics and Diseases of Women and Children in the Bellevue Hospital Medical College, Consulting Physician to the Maternity Hospital, etc , etc New Edition, revised and enlarged, with numerous illustrations 8vo, pp xviii, 763 New York D Appleton & Co , 1885 Chicago Jansen, McClurg & Co

It is now just four years since the first edition of this work was given to the public, and the favorable reception of that and the second edition rather preclude the necessity of an extended notice of this, the third edition Many changes in the text have been made in the present edition, and in some cases entire subjects have been rewritten, changes that have been rendered necessary by the great strides that have been made in scientific midwifery during the past three or four years The facts that the book has been so favorably received in this country and abroad, and that it has been translated into Spanish, French and Italian are sufficient to show that it has most unusual merits

ASSOCIATION ITEMS

REPORT OF THE LIBRARIAN

I have the honor to present the accompanying catalogue of additions made to the Library of the Association by donations, exchanges, purchase and subscription, during the past year The Catalogue submitted herewith shows that since last report, 183 distinct titles have been added, including 56 volumes of Transactions, Hospital Reports, Reports of Boards of Health, and Medical Journals not previously received and catalogued Also, that there has been an addition to the library of a number of valuable works by standard American authors, sent for review to the Editor of The Journal, and by him transmitted to the Library, which, with this increase, now contains 2,249 distinct titles, and comprehends about 6,500 volumes, including pamphlets

I would again draw the attention of the Association to the fact, that the present quarters of the Library are inadequate, and hope that some means may be found to make this valuable collection more accessible to the profession I recommend, as on former occasions, that the system of exchanges be continued and wherever possible, increased Also, that $200 be placed at the disposal of the Librarian, to be expended in binding periodicals, transactions, etc , and in the purchase of such journals, etc , as are needed to complete sets already on our shelves

My thanks are again due, and hereby expressed to the Editor of The Journal of the Association for his active cooperation, by prompt transmission to me of books, pamphlets, journals, etc, sent to him for review or as exchanges

Respectfully submitted

C H A KLEINSCHMIDT, M D,
Librarian
